1.0 INTRODUCTION

1.1 Purpose

The "Disposal of Coal Combustion Residuals (CCR) from Electric Utilities rule" (40 Code of Federal Regulations (40 CFR) Part 257), effective October 19, 2015, requires that existing CCR surface impoundments meeting the requirements of §257.73(b) conduct initial and periodic structural stability assessments in accordance with §257.73(d). This letter provides the structural stability assessment for the Monticello Steam Electric Station's (MOSES's) CCR Impoundments, identified as the Bottom Ash Ponds (BAPs) – the Southwest Ash Settling Pond (SASP), West Ash Settling Pond (WASP), and the Northeast Ash Water Retention Pond (NAWRP).

1.2 Site Background

The MOSES generates bottom ash, fly ash, boiler slag, and scrubber gypsum during electricity generation. The following surface impoundments, collectively referred to as the Bottom Ash Ponds (BAPs), shown on Figure 1, are in operation at the MOSES:

- Southwest Ash Settling Pond (SASP);
- West Ash Settling Pond (WASP); and
- Northeast Ash Water Retention Pond (NAWRP).

Each of these ponds are active, clay-lined, excavated impoundments surrounded and separated by engineered earthen berms. The WASP and NAWRP receive a slurry of bottom ash/boiler slag and water from the dewatering bins through two sets of pipes entering above the crest of the northern embankment. The WASP and NAWRP are used to separate the solids from the water using gravity sedimentation. A set of pipes pass above the crest near the northwestern corner of the SASP; however, these pipes are blanked off and have reportedly never been put into service. The SASP, connected to the WASP with two weirs, is used for overflow from the other two ponds. Water decanted from the WASP and the SASP ponds is returned to the power plant via the Low Pressure Ash Water (LPAW) pump station.

Four other surface impoundments are present at MOSES: the Rubber-lined Pond, (previously referred to as the scrubber pond), the North Operating Pond, the Low Volume Waste Pond, and the Runoff Collection Pond (RCP) which is located in the southeastern quadrant of the BAP area. The RCP collects stormwater runoff from the facility and is not hydraulically connected to the BAPs. These ponds are not subject to the CCR Rule.

1.3 Previous Slope Stability Evaluations

Golder performed previous evaluations on the BAPs as part of the reports listed below:

- Ash and Scrubber Pond Stability Investigation Report, Luminant Monticello SES, Titus County, Texas, dated December 2012
- Addendum to Ash and Scrubber Pond Stability Investigation Report, Luminant Monticello Power Plant, Titus County, Texas, dated March 2014.

These studies found the pond slopes to be adequately stable.

2.0 SUBSURFACE CONDITIONS

The MOSES site is located in the West Gulf Coastal Plain subprovince, in Titus County, Texas. The primary rock units in the region comprise sedimentary rocks of the Mesozoic and Cenozoic eras. The principal geologic unit in the region of the site is the Wilcox Group which is composed of interbedded sand, silt, silty shale, clay and lignite (Cook-Joyce Inc., 1985). The surficial soils of comprise of moderately well-drained to poorly drained loamy soils (USDA, 1990).

2.1 Site Geology

2.1.1 Subsurface Investigations and Laboratory Testing

Information from previous subsurface investigations was used to characterize the subsurface site conditions. Golder conducted a subsurface investigation for the surface impoundments in December 2012. Golder completed eight borings within the pond footprints with boring depths of 50 feet below ground surface (bgs). The boring map and select, representative boring logs are included in Appendix A.

As part of the investigation, laboratory testing was performed on selected samples, in accordance with commonly accepted methods and practices. Undisturbed and disturbed soil samples were tested to determine water content, Atterberg limits, grain size distribution, and shear strength. Water content determination was performed in accordance with ASTM D2216; Atterberg limits were determined in accordance with ASTM D4318; and grain size distribution was performed in accordance with ASTM D422. Shear strength testing consisted of unconsolidated-undrained (UU) and consolidated-undrained (CU) triaxial compression tests in general accordance with ASTM D2850 and D4767, respectively. Laboratory test summary sheets results are presented in Appendix B. The test results can be found in Appendix C.

The findings from the above subsurface investigations were reviewed for their applicability to this study, and are summarized in the following sections.

2.1.2 Subsurface Site Conditions

All eight borings of the subsurface investigation, were drilled along the crest of the BAPs embankments at approximate elevation 386.5 feet mean sea level (ft-msl). Hence, the borings consisted of fill and native soils. The soils encountered in the borings generally consisted of stiff to hard sandy clays and compact to dense sands. The subsurface stratigraphy generally consisted of interchanging layers of clayey sand and sandy clay. The clayey sand layers ranged in thickness from 2 to 20 feet where encountered. The sandy clay and clay layers varied in thickness from 2 to 33 feet where encountered. Four of the borings terminated in a sandy clay/clayey sand layer, while a layer of compact to dense, silty or poorly graded sand was encountered beneath the sandy clay/clayey sand layers in four borings.

Water was encountered in each of the eight borings. Water elevations encountered during drilling ranged from 352.1 to 375.05 ft-msl with an average of El. 358.5 ft-msl.

Groundwater levels measured in 2015, from wells surrounding the BAPs, indicate that the groundwater level varies from approximately EL 364 ft-msl in the southeast corner to EL 358 ft-msl in the northwest corner.

3.0 STRUCTURAL STABILITY ASSESSMENT - §257.73(d)(1)(i)-(vii)

The CCR rules require conducting periodic structural stability assessments by a qualified professional engineer to document whether the design, construction, operation and maintenance is consistent with recognized and generally accepted good engineering practices for the maximum volume of CCR and CCR wastewater that can be impounded therein.

3.1 Foundations and Abutments - §257.73(d)(1)(i)

As noted above, the foundation soils generally consist of stiff to hard sandy clays and compact to dense sand. As discussed below, the embankment fill appear to be well-compacted. The foundation soils and abutments are stable.

3.2 Slope Protection - §257.73(d)(1)(ii)

The downstream slopes of the BAP embankments are protected from erosion and deterioration by the establishment of a vegetative cover. The vegetative cover is inspected weekly for erosion, signs of seepage, animal burrows, sloughing, and plants that could negatively impact the embankment.

The interior slopes are protected from wave action by concrete revetment mats or riprap.

3.3 Dikes (Embankment) - §257.73(d)(1)(iii)

The BAPs at the MOSES were originally constructed in 1974 as a two-basin system. In 1990, the ponds were segregated and relined with a 3-foot thick clay liner. In addition, the interior slopes of the NAWRP, and the east side interior slopes of the WASP were lined with concrete revetment mats. Riprap was placed on all the remaining interior slopes of the ponds for erosion protection.

No construction documentation or testing details of the original embankment fill are available. Based on the borings, the embankments were likely constructed using a clayey fill from an on-site borrow source (Pastor, Behling and Wheeler, 2015). Golder's subsurface investigation of 2012, which comprised boreholes drilled into the embankment, found the embankment soils to generally consist of stiff to hard sandy clay, clayey sand, and clay, consistent with well-compacted fill.

No significant repairs have been performed to the BAP embankments since their initial construction, except the addition of an interior berms and a 3-foot thick clay liner in 1989. A shallow slope failure was observed at the northwestern corner of the WASP, on July 1, 2016. Based on our observations and previous inspections, it appears that the slope failure passes through fill placed against the original embankment slope and does not threaten the stability of the embankment.

Based on a review of past inspection reports and on recent observations, the BAP embankment is sufficient to withstand the range of loading conditions to which they are subjected.

3.4 Vegetated Slopes - §257.73(d)(1)(iv)

As of June 14, 2016 the US Court of Appeals for the District of Columbia Circuit issued an Order that remanded and vacated the CCR rule requirement that vegetation on the exterior portions of dikes on CCR surface impoundments be maintained not to exceed six inches in height. EPA will issue a new rulemaking in the future to address this issue.

Each of the surface impoundments at the MOSES are inspected weekly. Luminant maintains the vegetation in a manner that ensures adequate inspections can be conducted.

3.5 Spillways - §257.73(d)(1)(v)

There are no spillways on any of the surface impoundments.

3.6 Hydraulic Structures - §257.73(d)(1)(vi)

Two valve-controlled outlet structures with discharge pipes pass through the BAP embankment: a 3-foot diameter pipe through the western embankment near the southwestern corner of the WASP; and a pipe through the southern embankment of the SASP. These below-grade pipes are connected to concrete surge tanks, which are connected to a concrete chamber and pumps located west of the WASP.

Concrete weirs – two connecting the NAWRP to the WASP, and two connecting the WASP to the SASP – are present on the interior berms. Flow between the ponds is controlled with sluice gates.

All other piping to the BAPs passes above the crest of the embankments.

No significant deterioration, deformation, distortion, bedding deficiencies, sedimentation, or debris were observed that may negatively affect the operation of the surface impoundments.

3.7 Downstream Slopes Adjacent to Water Body - §257.73(d)(1)(vii)

The south side of the NAWRP and the east side of the SASP border the Storm Water Collection Pond. The water level in this pond is maintained below EL 365 ft-msl, and the base of the BAPs is at EL 361 ft-msl. Since the maximum water level in the Stormwater Collection Pond is only 4 feet above the base of the adjacent ponds, rapid removal of water will not significantly affect the stability of the BAP embankment.

3.8 Structural Stability Deficiencies - §257.73(d)(2)

No structural stability deficiencies were identified during this assessment.

4.0 CONCLUSION

Based on our review of the information provided by Luminant, on information prepared by Golder Associates Inc., and on our on-site observations, no structural stability deficiencies were identified in the surface impoundments during this assessment.

Golder appreciates the opportunity to assist Luminant with this project. If you have any questions, or require further assistance from Golder, please contact the undersigned at (281) 821-6868.

Golder Associates

Established in 1960, Golder Associates is a global, employee-owned organization that helps clients find sustainable solutions to the challenges of finite resources, energy and water supply and management, waste management, urbanization, and climate change. We provide a wide range of independent consulting, design, and construction services in our specialist areas of earth, environment, and energy. By building strong relationships and meeting the needs of clients, our people have created one of the most trusted professional services organizations in the world.
