Re: Hennepin Power Plant West Ash Pond System; IEPA ID # W1550100002-01-03

Dear Mr. LeCrone:

In accordance with 35 I.A.C. § 845.220(c) Dynegy Midwest Generation, LLC is submitting a corrective action construction permit application for the Hennepin Power Plant West Ash Pond System (IEPA ID # W1550100002-01-03). One hard copy is provided with this submittal.

The permit application was prepared in accordance with 35 I.A.C. § 845.220 (a) and (c). This submittal includes the completed permit application forms as required by § 845.210.

Sincerely,

Cynthia Vodopivec
SVP, Environmental, Health & Safety

Enclosures

Form CCR 1	Illinois Environmental Protection Agency CCR Surface Impoundment Permit Application Form CCR 1 – General Provisions

Bureau of Water ID Number:
W1550100002-01, 03

CCR Permit Number:
No Permit Issued

Facility Name:
Hennepin Power Plant

For IEPA Use Only

SECTION 1: FACILITY, OPERATOR, AND OWNER INFORMATION (35 Ill. Adm. Code 845.210(b))

Facility, Operator, and Owner Information

1.1	Facility Name		
	Hennepin Power Plant		
1.2	Illinois EPA CCR Permit Number (if applicable)		
	No Permit Issued		
1.3	Facility Contact Information		
	Name (first and last) Phil Morris	Title Senior Director - Environmental	Phone Number 618-343-7794
	Email address phil.morris@vistracorp.com		
1.4	Facility Mailing Address		
	Street or P.O. box 1500 Eastport Plaza Dr		
	City or town Collinsville	State IL	Zip Code 62234
1.5	Facility Location		
	Street, route number, or other specific identifier 13498 East 800th Street		
	County name Putnam	County code (if known)	
	City or town Hennepin	State Illinois	Zip Code 61327
1.6	Name of Owner/Operator		
	Dynegy Midwest Generation, LLC		

Facility, Operator, and Owner Info

1.7 Owner/Operator Contact Information

Name (first and last)	Title	Phone Number
Phil Morris	Senior Director - Environmental	618-343-7794

Email address: phil.morris@vistracorp.com

1.8 Owner/Operator Mailing Address

Street or P.O. box: 1500 Eastport Plaza Dr

City or town	State	Zip Code
Collinsville	IL	62234

SECTION 2: LEGAL DESCRIPTION (35 Ill. Adm. Code 845.210(c))

Legal Description

2.1 Legal Description of the facility boundary

See Attachment A.

SECTION 3: PUBLICLY ACCESSIBLE INTERNET SITE REQUIREMENTS (35 Ill. Adm. Code 845.810)

Internet Site

3.1 Web Address(es) to publicly accessible internet site(s) (CCR website)

www.luminant.com/illinois-ccr/

3.2 Is/are the website(s) titled "Illinois CCR Rule Compliance Data and Information"

☑	Yes	☐	No

SECTION 4: IMPOUNDMENT IDENTIFICATION

Impoundment Identification

4.1 List all the impoundment identification numbers for your facility and check the corresponding box to indicate that you have attached a written description for each impoundment.

W1550100002-01 (see Attachment A)	☑	Attached written description
W1550100002-03 (see Attachment A)	☑	Attached written description
	☐	Attached written description
	☐	Attached written description

Form CCR 2CA	Illinois Environmental Protection Agency CCR Surface Impoundment Permit Application Form CCR 2CA – Corrective Action Construction

Bureau of Water ID Number:
W1550100002

CCR Permit Number:
No Permit Issued

Facility Name:
Hennepin Power Plant

For IEPA Use Only

SECTION 1: DESIGN AND CONSTRUCTION PLANS (35 Ill. Adm. Code 845.220)

Design and Construction Plans

1.1	CCR surface impoundment name.
	Old West Ash Pond (Pond No. 1 and No. 3); Old West Ash Polishing Pond
1.2	Identification number of the CCR surface impoundment (if one has been assigned by the Agency).
	W1550100002-01,03
1.3	Describe the boundaries of the CCR surface impoundment (35 Ill. Adm. Code 845.210 (c)).
	See Attachment A
1.4	State the purpose for which the CCR surface impoundment is being used.
	See Attachment C
1.5	How long has the CCR surface impoundment been in operation?
	See Attachment C
1.6	List the types of CCR that have been placed in the CCR surface impoundment.
	See Attachment D
1.7	List the name of the watershed within which the CCR surface impoundment is located.
	See Attachment F

Design and Construction Plans (Continued)

1.8	What is the size in acres of the watershed within which the CCR surface impoundment is located?	
	See Attachment C	
1.9	Check the corresponding boxes to indicate that you have attached the following:	
	☑	Drawings satisfying the requirements of 35 Ill. Adm. Code 845.220(a)(1)(F).
	☑	A description of the type, purpose, and location of existing instrumentation.
	☑	Area capacity curves for the CCR Impoundment.
	☑	A description of each spillway and diversion design features and capacities and provide the calculations used in their determination.
	☑	The construction specifications and provisions for surveillance, maintenance, and repair of the CCR surface impoundment.
	☑	A description of the physical and engineering properties of the foundation and abutment materials on which the CCR surface impoundment is constructed.
	☑	A statement of the type, size, and physical and engineering properties of the materials used in constructing each zone or stage of the CCR surface impoundment.
	☑	A statement of the method of site preparation and construction of each zone of the CCR impoundment.
	☑	A statement of the approximate dates of construction of each successive stage of construction of the CCR surface impoundment.
1.10.1	Is there any record or knowledge of structural instability of the CCR surface impoundment?	
	☐ Yes	☑ No
1.10.2	If you answered yes to Item 1.10.1, provide detailed explanation of the structural instability.	

SECTION 2: NARRATIVE DESCRIPTION OF THE FACILITY (35 Ill. Adm. Code 845.220)

Narrative Description

2.1	List the types of CCR expected in the CCR surface impoundments.
	See Attachment D

Narrative Description (Cont.)	2.2	Have you attached a chemical analysis of each type of expected CCR?			
		☑	Yes		
	2.3	Estimate of the maximum capacity of the surface impoundment in gallons or cubic yards.			
		See Attachment C			
	2.4	Enter the rate at which CCR and non-CCR waste streams currently enter the CCR impoundment in gallons per day and dry tons.			
		See Attachment C	GPD	See Attachment C	dTn
	2.5	Estimate length of time the CCR surface impoundment will receive CCR and non-CCR waste streams.			
		See Attachment C			
	2.6	Have you attached an on-site transportation plan that includes all existing and planned roads in the facility that will be used during the operation of the CCR surface impoundment?			
		☑	Yes		
SECTION 3: MAPS (35 Ill. Adm. Code 845.220)					
Maps	3.1	Check the corresponding boxes to indicate that you have attached the following maps:			
		☑	A site location map on the most recent United Sates Geological Survey (USGS) quadrangle of the area from the 7 ½ minute series (topographic) or on another map whose scale clearly shows the information required in 35 Ill. Adm. Code 845.220(a)(3).		
		☑	Site plans maps satisfying the requirements of 35 Ill. Adm. Code 845.220(a)(4).		
SECTION 4: ATTACHMENTS					
Attachments	4.1	Check the corresponding boxes to indicate that you have attached the following:			
		☑	A narrative description of the proposed construction of, or modification to, a CCR surface impoundment and any projected changes in the volume or nature of the CCR or non-CCR waste streams.		
		☑	Plans and specifications fully describing the design, nature, function, and interrelationship of each individual component of the facility.		
		☑	The signature and seal of a qualified professional engineer.		
		☑	Certification that the owner or operator of the CCR surface impoundment completed the public notification and public meetings required under 35 Ill. Adm. Code 845.240.		
		☑	A summary of the issues raised by the public during the public notification and public meetings.		
		☑	A summary of any revisions, determinations, or other considerations made in response to those issues raised by the public during the public notification and public meetings.		
		☑	Certification that all contractors, subcontractors, and installers utilized to construct, install, modify, or close a CCR surface impoundment are participants in a training program that is approved by and registered with the U.S. Department of Labor's Employment and Training Administration and that includes instruction in erosion control and environmental remediation.		

		☑	Certification that all contractors, subcontractors, and installers utilized to construct, install, modify, or close a CCR surface impoundment are participants in a training program that is approved by and registered with the U.S. Department of Labor's Employment and Training Administration and that includes instruction in the operation of heavy equipment and excavation.
SECTION 5: GROUNDWATER MONITORING PROGRAM			
Groundwater Monitoring	5.1	Indicate that you have attached the following components of a new groundwater monitoring program or any modifications to an existing groundwater monitoring program by checking the corresponding boxes:	
		☑	A hydrogeologic site investigation meeting the requirements of 35 Ill. Adm. Code 845.620, if applicable.
		☑	Design and construction plans of a groundwater monitoring system meeting the requirements of 35 Ill. Adm. Code 845.630.
		☑	A proposed groundwater sampling and analysis program that includes selection of the statistical procedures to be used for evaluating groundwater monitoring data as required by 35 Ill. Adm. Code 845.640 and 845.650.
SECTION 6: CORRECTIVE ACTION (35 Ill. Adm. Code 845.220(c))			
Corrective Action	6.1	Indicate that you have attached a corrective action plan as specified in 35 Ill. Adm. Code 845.670 by checking the box below:	
		☑	Corrective action plan as specified in 35 Ill. Adm. Code 845.670.
		☑	Corrective action groundwater monitoring program, including identification of revisions to the groundwater system for corrective action.
		☑	Any interim measures necessary to reduce the contaminants leaching from the CCR surface impoundment, and/or potential exposures to human or ecological receptors, including an analysis of the factors specified in 35 Ill. Adm. Code 845.680(a)(3).
SECTION 7: GROUNDWATER MODELING (35 Ill. Adm. Code 845.220(c))			
Groundwater Modeling	7.1	Indicate that you have attached the following by checking the corresponding boxes:	
		☑	The results of groundwater contaminant transport modeling and calculations showing how the corrective action will achieve compliance with the applicable groundwater standards.
		☑	All modeling inputs and assumptions.
		☑	Description of the fate and transport of contaminants with the selected corrective action over time.
		☑	Capture zone modeling, if applicable.
		☑	Any necessary licenses and software needed to review and access both the model and the data contained within the models required by 35 Ill. Adm. Code 845.220(c)(2).

CONSTRUCTION PERMIT APPLICATION
Hennepin Power Plant – West Ash Pond System

Appendix A
LEGAL DESCRIPTION
§845.210(c)
Legal description of the facility

Appendix B.1
CORRECTIVE ACTION GROUNDWATER MONITORING PLAN
§845.680(a)(1)
Plan that establishes how data will be collected, documented, and evaluated to assess remedy effectiveness

Appendix B.2
HYDROGEOLOGIC SITE CHARACTERIZATION REPORT
§845.620
Hydrogeology, groundwater quality data, conceptual site model

Appendix C
HISTORY OF CONSTRUCTION
§845.220(a)(1)
Construction and operational history of the CCR surface impoundment

Appendix D
TYPES OF CCR AND CHEMICAL CONSTITUENTS
§845.220(a)(2)(A)
Types of CCR expected in the CCR surface impoundment, including chemical analysis of each type

Appendix E & F
SITE PLAN MAP & TRANSPORTATION MAP
§845.220(a)(3) and (a)(4)
Maps showing the facility and existing CCR surface impoundments, site boundaries, groundwater monitoring wells, access roads and transportation corridors

Appendix G
CORRECTIVE ACTION PLAN
§845.670
Identifies the selected remedy based on the results of the Corrective Measures Assessment

Appendix H
GEOTECHNICAL INFORMATION
Geotechnical information and calculations to support permit-level design

Appendix I
PUBLIC NOTIFICATION
§845.220(a)(9)
Certification that public notification and public meeting have been completed required under *§845.240*

Appendix J
CONTRACTOR CERTIFICATION
415 ILCS 5/22.59(b)(4)
Certification that CCR owner/operator will utilize contractors who are participants in an approved training program

Appendix A
CORRECTIVE ACTION ALTERNATIVE ANALYSIS (CAAA)
§845.670(e)
Evaluation of potential viable corrective actions identified in the Corrective Measures Assessment

Appendix B
DRAWINGS AND MATERIAL SPECIFICATIONS
Permit-level design drawings and specifications

Appendix A
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT
§845.670(f)(4)
Evaluation of potential risks to human and ecological receptors

Appendix B
CAAA SUPPORTING INFORMATION REPORT
§845.670(e)
Information to support preparation of CAAA

Appendix C
CORRECTIVE MEASURES ASSESSMENT
§845.660
Assessment of potential corrective measure technologies to address GWPS exceedances at the CCR surface impoundment

Appendix D
NATURE AND EXTENT REPORT AND ADDENDUM
§845.650(d)(1)
Documents the nature and extent of constituents detected above the GWPS that are attributable to the CCR surface impoundment

Appendix E
GROUNDWATER POLISHING REPORT
§845.220(c)(2)
Presents results of geochemical modeling used to evaluate chemical mechanisms on groundwater polishing under current conditions and after implementation of the corrective measure

Appendix A
FEASIBILITY LEVEL DRAWINGS
Conceptual design drawings showing approximate extents and details of alternatives presented in the CAAA

Appendix B.1
GROUNDWATER MODELING TECHNICAL MEMORANDUM
§845.220(c)(2)
Presents additional groundwater modeling simulations and incorporates data collected since 2022 modeling (Appendix B.2) to support alternatives presented in the CAAA

Appendix B.2
2022 GROUNDWATER MODELING REPORT
§845.220(c)(2)
Presents results of 2022 MODFLOW and MT3DMS groundwater flow and transport models to evaluate potential alternatives

Appendix C
LABOR/MILEAGE ESTIMATES
Detailed material quantity, labor and mileage estimates for alternatives presented in the CAAA

Section 845.220 - Construction Permits								
845.220(a)	All construction permit applications must contain the following information and documents.							
845.220(a)(1)	Design and Construction Plans (Construction History)	CPA	Appendix C	1042	X			
845.220(a)(2)	Narrative Description of the Facility. The permit application must contain a written description of the facility with supporting documentation describing the procedures and plans that will be used at the facility to comply with the requirements of this Part. The descriptions must include, but are not limited to, the following information:	CPA	Section 2.2	18			X	
845.220(a)(2)(A)	The types of CCR expected in the CCR surface impoundment, including a chemical analysis of each type of expected CCR;	CPA	Section 2.2	18		X		
845.220(a)(2)(B)	An estimate of the maximum capacity of each surface impoundment in gallons or cubic yards;	CPA	Section 2.2	18		X		
845.220(a)(2)(C)	The rate at which CCR and non-CCR waste streams currently enter the CCR surface impoundment in gallons per day and dry tons;	CPA	Section 2.2	18		X		
845.220(a)(2)(D)	The estimated length of time the CCR surface impoundment will receive CCR and non-CCR waste streams; and	CPA	Section 2.2	18		X		
845.220(a)(2)(E)	An on-site transportation plan that includes all existing and planned roads in the facility that will be used during the operation of the CCR surface impoundment.	CPA	Section 2.2	18			X	
845.220(a)(3)	Site Location Map. All permit applications must contain a site location map on the most recent United States Geological Survey (USGS) quadrangle of the area from the 7½ minute series (topographic), or on such other map whose scale clearly shows the following information:	CPA	Appendix F	1197		X		
845.220(a)(3)(A)	The facility boundaries and all adjacent property, extending at least 1000 meters (3280 feet) beyond the boundary of the facility;	CPA	Appendix F	1197		X		
845.220(a)(3)(B)	All surface waters;	CPA	Appendix F	1197		X		
845.220(a)(3)(C)	The prevailing wind direction;	CPA	Appendix F	1197		X		
845.220(a)(3)(D)	The limits of all 100-year floodplains;	CPA	Appendix F	1197		X		
845.220(a)(3)(E)	All natural areas designated as a Dedicated Illinois Nature Preserve under the Illinois Natural Areas Preservation Act [525 ILCS 30];	CPA	Appendix F	1197		X		
845.220(a)(3)(F)	All historic and archaeological sites designated by the National Historic Preservation Act (16 USC 470 et seq.) and the Illinois Historic Sites Advisory Council Act [20 ILCS 3410]; and	CPA	Appendix F	1197		X		
845.220(a)(3)(G)	All areas identified as critical habitat under the Endangered Species Act of 1973 (16 USC 1531 et seq.) and the Illinois Endangered Species Protection Act [520 ILCS 10].	CPA	Appendix F	1197		X		
845.220(a)(4)	Site Plan Map. The application must contain maps, including cross-sectional maps of the site boundaries, showing the location of the facility. The following information must be shown:	CPA	Appendix E	1195		X		
845.220(a)(4)(A)	The entire facility, including any proposed and all existing CCR surface impoundment locations;	CPA	Appendix E	1195		X		
845.220(a)(4)(B)	The boundaries, both above and below ground level, of the facility and all CCR surface impoundments or landfills containing CCR included in the facility;	CPA	Appendix E	1195		X		
845.220(a)(4)(C)	All existing and proposed groundwater monitoring wells; and	CPA	Appendix E	1195		X		
845.220(a)(4)(D)	All main service corridors, transportation routes, and access roads to the facility.	CPA	Appendix E	1195		X		
845.220(a)(5)	A narrative description of the proposed construction of, or modification to, a CCR surface impoundment and any projected changes in the volume or nature of the CCR or non-CCR waste streams.	CPA	Section 2.4	20			X	
845.220(a)(6)	Plans and specifications fully describing the design, nature, function and interrelationship of each individual component of the facility.	CPA	Appendix G	1199			X	
845.220(a)(7)	A new groundwater monitoring program or any modification to an existing groundwater monitoring program that includes but is not limited to the following information:	CPA	Appendix B.1	34			X	
845.220(a)(7)(A)	A hydrogeologic site investigation meeting the requirements of Section 845.620, if applicable;	CPA	Appendix B.2	124	X			
845.220(a)(7)(B)	Design and construction plans of a groundwater monitoring system meeting the requirements of Section 845.630; and	CPA	Section 2.6	22			X	
845.220(a)(7)(C)	A proposed groundwater sampling and analysis program that includes selection of the statistical procedures to be used for evaluating groundwater monitoring data, as required by Sections 845.640 and 845.650.	CPA	Appendix B.1	34			X	
845.220(a)(8)	The signature and seal of a qualified professional engineer	CPA	Section 2.7	24			X	
845.220(a)(9)	Certification that the owner or operator of the CCR surface impoundment completed the public notification and public meetings required under Section 845.240, a summary of the issues raised by the public, a summary of any revisions, determinations, or other considerations made in response to those issues, and a list of interested persons in attendance who would like to be added to the Agency's listserv for the facility.	CPA	Appendix I	2937			X	
845.220(c)	Corrective Action Construction. In addition to the requirements in subsection (a), all construction permit applications that include any corrective action performed under Subpart F must also contain the following information and documents:							
845.220(c)(1)	Corrective action plan (see Section 845.670);	CPA	Appendix G	1199			X	
845.220(c)(2)	Groundwater modeling, including:	CPA	Appendix G	1199			X	
845.220(c)(2)(A)	The results of groundwater contaminant transport modeling and calculations showing how the closure will achieve compliance with the applicable groundwater standards;	CPA	Appendix G	1199			X

845.220(c)(2)(B)	All modeling inputs and assumptions;	GWTM	Section 2	1372			X	
845.220(c)(2)(C)	Description of the fate and transport of contaminants, with the selected closure over time; and	CPA	Appendix G	1199			X	
845.220(c)(2)(D)	Capture zone modeling, if applicable.	CPA	Appendix G	1199			X	
845.220(c)(3)	Any necessary licenses and software needed to review and access both the models and the data contained within the models required by subsection (c)(2);	CPA	Section 2.9	25			X	
845.220(c)(4)	Corrective action groundwater monitoring program, including identification of revisions to the groundwater monitoring system for corrective action; and	CPA	Section 2.9	25			X	
845.220(c)(5)	Any interim measures necessary to reduce the contaminants leaching from the CCR surface impoundment, and/or potential exposures to human or ecological receptors, including an analysis of the factors specified in Section 845.680(a)(3).	CPA	Section 2.9	25			X	
Section 845.620 - Hydrogeologic Site Characterization								
845.620(a)	The owner or operator of the CCR surface impoundment must design and implement a hydrogeologic site characterization.	CPA	Appendix B.2	124	X			Additional hydrogeologic site characterization information is also provided in the Nature & Extent Report - location depicted on the visual roadmap above.
Section 845.670 - Corrective Action Plan								
845.670(b)	Within one year after completing the assessment of corrective measures as specified in 35 I.A.C. § 845.660, and after completion of the public meeting in 35 I.A.C. § 845.660(d), the owner or operator of the CCR surface impoundment must submit, in a CP application [or modification to the facility's operating permit] to IEPA, a CAP that identifies the selected remedy. This requirement applies in addition to, not in place of, any applicable standards under any other State or federal law.	CPA	Appendix G	1199			X	
845.670(c)	The CAP must meet the following requirements:							
845.670(c)(1)	Be based on the results of the CMA conducted under 35 I.A.C. § 845.660;	CAAA	Appendix C	1484				
845.670(c)(2)	Identify a selected remedy that at a minimum, meets the standards listed in subsection (d);	CAAA	Section 2	1250			X	
845.670(c)(3)	Contain the corrective action alternatives analysis specified in subsection (e); and	CAAA	Section 2	1250			X	
845.670(c)(4)	Contain proposed schedules for implementation, including an analysis of the factors in subsection (f).	CAP	Table 2	1221			X	
845.670(d)	The selected remedy in the CAP must:							
845.670(d)(1)	Be protective of human health and the environment;	CAAA	Section 2.2.1	1256			X	
845.670(d)(2)	Attain the GWPS specified in 35 I.A.C. § 845.600;	GWTM	Section 4	1385			X	
845.670(d)(3)	Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in 35 I.A.C. § 845.600 into the environment;	CAAA	Section 2.2.2	1257			X	
845.670(d)(4)	Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, taking into account factors such as avoiding inappropriate disturbance of sensitive ecosystems; and	CAAA	Section 2.5	1271			X	
845.670(d)(5)	Comply with standards for management of wastes as specified in 35 I.A.C. § 845.680(d).	CAAA	Section 2	1250				
845.670(e)	CAAA. In selecting a remedy that meets the standards of subsection (d), the owner or operator of the CCR surface impoundment must consider the following evaluation factors:							
845.670(e)(1)	The long- and short-term effectiveness and protectiveness of each potential remedy, along with the degree of certainty that the remedy will prove successful based on consideration of the following:	CAAA	Section 2.2	1256			X	
845.670(e)(1)(A)	Magnitude of reduction of existing risks;	CAAA	Section 2.2.1	1256			X	
845.670(e)(1)(B)	Magnitude of residual risks in terms of likelihood of further releases due to CCR remaining following implementation of a remedy;	CAAA	Section 2.2.3	1258			X	
845.670(e)(1)(C)	The type and degree of long-term management required, including monitoring, operation, and maintenance;	CAAA	Section 2.2.4	1258			X	
845.670(e)(1)(D)	Short-term risks that might be posed to the community or the environment during implementation of a remedy, including potential threats to human health and the environment associated with excavation, transportation, and re-disposal of contaminants;	CAAA	Section 2.2.5	1259			X	
845.670(e)(1)(E)	Time until GWPS in 35 I.A.C. § 845.600 are achieved;	CAAA	Section 2.2.6	1264			X	
845.670(e)(1)(F)	The potential for exposure of humans and environmental receptors to remaining wastes, considering the potential threat to human health and the environment associated with excavation, transportation, re-disposal, containment, or changes in groundwater flow;	CAAA	Section 2.2.7	1265			X	
845.670(e)(1)(G)	The long-term reliability of the engineering and institutional controls, including an analysis of any off-site, nearby destabilizing activities; and	CAAA	Section 2.2.8	1266			X	
845.670(e)(1)(H)	Potential need for replacement of the remedy.	CAAA	Section 2.2.9	1267			X	
845.670(e)(2)	The effectiveness of the remedy in controlling the source to reduce further releases based on consideration of each of the following potential factors:	CAAA	Section 2.2.2	1257			X	
845.670(e)(2)(A)	The extent to which containment practices will reduce further releases; and	CAAA	Section 2.2.2	1257			X	
845.670(e)(2)(B)	The extent to which treatment technologies may be used.	CAAA	Section 2.2.2	1257			X

845.670(f)	The owner or operator must specify, as part of the CAP, a schedule for implementing, of and completing, remedial activities. The schedule must require the completion of remedial activities within a reasonable time, taking into consideration the factors in this subsection (f). The owner or operator of the CCR surface impoundment must consider the following factors in determining the schedule of remedial activities:							
845.670(f)(1)	Extent and nature of contamination, as determined by the characterization required under 35 I.A.C. § 845.650(d);	CAP	Section 3.3	1213			X	
845.670(f)(2)	Reasonable probabilities of remedial technologies achieving compliance with the GWPS established by 35 I.A.C. § 845.600 and other objectives of the remedy;	CAP	Section 3.3	1213			X	
845.670(f)(3)	Availability of treatment or disposal capacity for CCR managed during implementation of the remedy;	CAP	Section 3.3	1213			X	
845.670(f)(4)	Potential risks to human health and the environment from exposure to contamination before completion of the remedy;	CAP	Section 3.3	1213			X	
845.670(f)(5)	Resource value of the aquifer, including:							
845.670(f)(5)(A)	Current and future uses, including potential residential, agricultural, commercial industrial and ecological uses;	CAP	Section 3.3	1213			X	
845.670(f)(5)(B)	Proximity and withdrawal rate of users;	CAP	Section 3.3	1213			X	
845.670(f)(5)(C)	Groundwater quantity and quality;	CAP	Section 3.3	1213			X	
845.670(f)(5)(D)	The potential impact to the subsurface ecosystem, wildlife, other natural resources, crops, vegetation, and physical structures caused by exposure to CCR constituents;	CAP	Section 3.3	1213			X	
845.670(f)(5)(E)	The hydrogeologic characteristic of the facility and surrounding land; and	CAP	Section 3.3	1213			X	
845.670(f)(5)(F)	The availability of alternative water supplies; and	CAP	Section 3.3	1213			X	
845.670(f)(6)	Other relevant factors.	CAP	Section 3.3	1213			X	
Section 845.680 Implementation of the Corrective Action Plan								
845.680(a)	Within 90 days after the Agency's approval of the corrective action plan submitted under Section 845.670, the owner or operator must initiate corrective action. Based on the schedule approved by the Agency for implementation and completion of corrective action, the owner or operator must:							
845.680(a)(1)	Establish and implement a corrective action groundwater monitoring program that:							
845.680(a)(1)(A)	At a minimum, meets the requirements of the monitoring program under Section 845.650;	CA GMP	Section 2.1	44			X	
845.680(a)(1)(B)	Documents the effectiveness of the corrective action remedy; and	CA GMP	Section 3	48			X	
845.680(a)(1)(C)	Demonstrates compliance with the groundwater protection standard under subsection (c).	CA GMP	Section 3	48			X	
845.680(a)(2)	Implement the corrective action remedy approved by the Agency under Section 845.670; and	CAP	Section 1.4	1205			X	
845.680(a)(3)	Take any interim measures necessary to reduce the contaminants leaching from the CCR surface impoundment, and/or potential exposures to human or ecological receptors. Interim measures must, to the greatest extent feasible, be consistent with the objectives of, and contribute to the performance of, any remedy that may be required by Section 845.670. The following factors must be considered by an owner or operator in determining whether interim measures are necessary:							
845.680(a)(3)(A)	Time required to develop and implement a final remedy;	CAP	Section 3.4	1216			X	
845.680(a)(3)(B)	Actual or potential exposure of nearby populations or environmental receptors to any of the constituents listed in Section 845.600;	CAP	Section 3.4	1216			X	
845.680(a)(3)(C)	Actual or potential contamination of sensitive ecosystems or current or potential drinking water supplies;	CAP	Section 3.4	1216			X	
845.680(a)(3)(D)	Further degradation of the groundwater that may occur if remedial action is not initiated expeditiously;	CAP	Section 3.4	1216			X	
845.680(a)(3)(E)	Weather conditions that may cause any of the constituents listed in Section 845.600 to migrate or be released;	CAP	Section 3.4	1216			X	
845.680(a)(3)(F)	Potential for exposure to any of the constituents listed in Section 845.600 as a result of an accident or failure of a container or handling system; and	CAP	Section 3.4	1216			X	
845.680(a)(3)(G)	Other situations that may pose threats to human health and the environment.	CAP	Section 3.4	1216			X

1. INTRODUCTION

Dynegy Midwest Generation, LLC (DMG) is the owner of the inactive coal-fired Hennepin Power Plant (HPP), also referred to as the Hennepin Power Station (HEN), in Hennepin, Putnam County, Illinois. According to the Illinois Environmental Protection Agency (IEPA), this power plant had five coal combustion residuals (CCR) surface impoundments, as listed in **Table 1** below. This Construction Permit Application (application) is for groundwater corrective action activities at the West Ash Pond System (WAPS) only. The WAPS is a CCR multi-unit which contains the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). Closure of WAPS was completed in 2020; this included leaving CCR in place within the OWAP, removing all CCR from the OWPP, placing it within the OWAP, and installing a geomembrane final cover system over the consolidated OWAP [1, 2].

Table 1 – CCR Surface Impoundments at Hennepin Power Plant

Impoundment Name	Status	Acronym	IEPA ID Number	Vistra CCR Unit ID	National Inventory of Dams Number
East Ash Pond	Inactive	EAP	W1550100005-05	803	IL50363
Old West Ash Pond (Pond No. 1 and Pond No. 3)	**Closed**	**WAPS (West Ash Pond System)**	**W1550100002-01**	**804**	**IL50698**
Old West Polishing Pond			**W1550100002-03**	**804**	
Ash Pond No. 2	Closed	AP2	W1550100002-04	802	IL50363
Ash Pond No. 4		AP4	W1550100002-07	805	None

Note – Bold indicates impoundments included in this Corrective Action Construction Permit Application

This Construction Permit Application for Groundwater Corrective Action activities was developed in accordance with Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments [3]

1.1 Legal Description

Section 845.210(c): All permit applications must contain a legal description of the facility boundary and a description of the boundaries of all units included in the facility.

A legal description of the facility is provided in **Appendix A**.

1.2 Previous Assessments

Section 845.210(d): Previous Assessments, Investigations Plans, and Programs

The WAPS is also regulated by Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257, herein referred to as the Federal CCR Rule [4] and subsequently became regulated by 35 I.A.C. § 845 [3]. Several assessments and plans were completed for the WAPS to satisfy the requirements of both the Federal CCR Rule and 35 I.A.C. § 845; some of which are referred to within and attached to this application.

Section 845.210(d)(1): The Agency may approve the use of any hydrogeologic site investigation or characterization, groundwater monitoring well or system, or groundwater monitoring plan, bearing the seal and signature of an Illinois Licensed Professional Geologist or Licensed Professional Engineer, completed before April 21, 2021 to satisfy the requirements of this Part.

A hydrogeologic site investigation and characterization report was prepared for the WAPS in 2017 [5] and is included as **Appendix B.2**. A Corrective Action Groundwater Monitoring Plan has been developed to support this Construction Permit Application and is provided in **Appendix B.1**.

Section 845.210(d)(2): For existing CCR surface impoundments, the owner or operator of the CCR surface impoundment may use a previously completed location restriction demonstration required by Section 845.300 (Placement Above the Uppermost Aquifer), Section 845.310 (Wetlands), Section 845.320 (Fault Areas), Section 845.330 (Seismic Impact Zones), and Section 845.340 (Unstable Areas) provide4845.d that the previously completed assessments meet the applicable requirements of those Sections.

No such previous assessments for Placement Above the Uppermost Aquifer, Wetlands, Fault Areas, Seismic Impact Zones, and/or Unstable Areas are included within this Construction Permit Application.

Section 845.210(d)(3): For existing CCR surface impoundments, the owner or operator of the CCR surface impoundment may use a previously completed assessment to serve as the initial assessment required by Section 845.440 (Hazard Potential Classification Assessment), Section 845.450 (Structural Stability Assessment) and Section 845.460 (Safety Factor Assessment) provided that the previously completed assessment: A) Was not completed more than five years ago; and B) Meets the applicable requirements of those Sections.

No such previous assessments for the Hazard Potential Classification, Structural Stability, and/or Safety Factors are included within this Construction Permit Application.

Section 845.210(d)(4): For inactive closed CCR surface impoundments, the owner or operator of the CCR surface impoundment may use a post-closure care plan previously approved by the Agency.

A post-closure care plan for the WAPS was previously submitted to the IEPA on December 20, 2017 [6]. The post-closure care plan was subsequently approved by the IEPA in 2018 [7].

2. CONSTRUCTION PERMIT

2.1 History of Construction

Section 845.220(a)(1): Design and Construction Plans (Construction History)

The initial History of Construction report for the WAPS and subsequent update prepared in 2021 are provided in **Appendix C**.

2.2 Narrative Description of Facility

Section 845.220(a)(2): Narrative Description of the Facility. The permit application must contain a written description of the facility with supporting documentation describing the procedures and plans that will be used at the facility to comply with the requirements of this Part. The descriptions must include, but are not limited to, the following information:

The Facility Narrative Description details are described in the following sections.

Section 845.220(a)(2)(A): The types of CCR expected in the CCR surface impoundment, including a chemical analysis of each type of expected CCR;

The types of CCR expected in the WAPS and analysis of the chemical constituents found within the CCR in the WAPS is provided in **Appendix D**.

Section 845.220(a)(2)(B): An estimate of the maximum capacity of each surface impoundment in gallons or cubic yards;

Prior to closure, the OWAP was estimated to contain approximately 590,000 cubic yards (CY) of CCR [8]. During closure, approximately 158,000 CY of additional material was placed beneath the final cover system. This included approximately 69,000 CY of CCR and non-CCR materials removed from the OWPP, 28,000 CY of materials excavated from the adjacent Hennepin Power Plant coal yard, and 61,000 CY of clean fill materials that were obtained on-site. This results in a total maximum capacity of the WAPS of approximately 748,000 CY.

Section 845.220(a)(2)(C): The rate at which CCR and non-CCR waste streams currently enter the CCR surface impoundment in gallons per day and dry tons;

There are no waste streams currently entering or will enter the WAPS in the future as final closure of the WAPS has been completed.

Section 845.220(a)(2)(D): The estimated length of time the CCR surface impoundment will receive CCR and non-CCR waste streams; and

There are no CCR or other non-CCR waste streams that are currently entering the WAPS or will enter the WAPS in the future as closure of the WAPS has been completed.

Section 845.220(a)(2)(E): An on-site transportation plan that includes all existing and planned roads in the facility that will be used during the operation of the CCR surface impoundment.

An On-Site Transportation Plan was developed as required by 35 I.A.C. § 845.220(a)(2)(E) and is provided for the WAPS in **Appendix E** that includes all on-site access roads and the surrounding roadways.

2.3 Site Maps

Section 845.220(a)(3): Site Location Map. All permit applications must contain a site location map on the most recent United States Geological Survey (USGS) quadrangle of the area from the 7½ minute series (topographic), or on another map whose scale clearly shows the following information:

A. The facility boundaries and all adjacent property, extending at least 1000 meters (3280 feet) beyond the boundary of the facility;

B. All surface waters;

C. The prevailing wind direction;

D. The limits of all 100-year floodplains;

E. All-natural areas designated as a Dedicated Illinois Nature Preserve under the Illinois Natural Areas Preservation Act [525 ILCS 30];

F. All historic and archaeological sites designated by the National Historic Preservation Act (16 USC 470 et seq.) and the Illinois Historic Sites Advisory Council Act [20 ILCS 3410]; and

G. All areas identified as critical habitat under the Endangered Species Act of 1973 (16 USC 1531 et seq.) and the Illinois Endangered Species Protection Act [520 ILCS 10].

A Site Location Map for the WAPS showing the information required in 35 I.A.C. § 845.220(a)(3) is provided in **Appendix F**. The Site Location Map consists of the most recent USGS topographic map (2024) which contains the facility and at least 1,000 meters of the surrounding area. Information included on the Site Location Map meets the requirements for a Flood Hazard Map, Topographic Vicinity Map, Designated Nature Map, Designated Historic and Archeological Site Map, and Identified Critical Habitat Map.

The data in the Site Location Map was collected by performing a comprehensive search of the Illinois Department of Natural Resources (IDNR) natural heritage database [9] for natural and protected areas within 1,000 meters of the WAPS. Within Putnam and adjacent Bureau County, a total of 21 sites were identified from the Illinois Natural Areas Inventory and 8 were identified from the Illinois Nature Preserves list. None of the natural areas or preserves fall within 1,000 meters of the WAPS.

The IDNR natural heritage database also includes a list of Endangered Species by County [10] and notes that a total of 52 threatened and endangered species as located within Putnam County and adjacent Bureau County, including 33 endangered and 19 threatened species. A review of the U.S. Fish and Wildlife Service (USFWS) Threatened & Endangered Species Active Critical Habitat Report [11] identified critical habitat for the endangered Indiana Bat located in adjacent Bureau County, on the opposite bank of the Illinois River from the Site and located within 1,000 meters of the WAPS.

A search of the IDNR Historic and Architectural Resources Geographic Information System (HARGIS) database [12] for historical sites within 1,000 meters of the Site located no results.

The 100-year flood plain limits were obtained from the Federal Emergency Management Area (FEMA) Flood Map Service Center [13]. The 100-year flood plain of the Illinois River is directly adjacent to the WAPS but does not extend over the existing final cover system.

Section 845.220(a)(4): Site Plan Map. The application must contain maps, including cross-sectional maps of the site boundaries, showing the location of the facility. The following information must be shown:

A. The entire facility, including any proposed and all existing CCR surface impoundment locations;

B. The boundaries, both above and below ground level, of the facility and all CCR surface impoundments or landfills containing CCR included in the facility;

C. All existing and proposed groundwater monitoring wells; and

D. All main service corridors, transportation routes, and access roads to the facility.

The Site Plan Map for the WAPS showing the information required in 35 I.A.C. § 845.220(a)(4) is provided in **Appendix E**.

2.4 Narrative Description of Proposed Construction

Section 845.220(a)(5): A narrative description of the proposed construction of, or modification to, a CCR surface impoundment and any projected changes in the volume or nature of the CCR or non-CCR waste streams.

The proposed modification for the WAPS will consist of supplementing the completed source control [1, 2] with the installation of a vertically- and laterally-continuous permanent and low-permeability deep cutoff wall (DCW) that will extend from the perimeter dikes of the WAPS into competent, low-permeability shale bedrock beneath the WAPS to form a continuous containment system (CCS). The CCS, as outlined in the Corrective Action Plan for the WAPS (see **Appendix G**), will result in CCR within the WAPS being physically isolated from the environment on all sides by a permanent, passive system of continuous low-permeability barriers, including the final cover system on the top, the DCW on the sides, and competent shale bedrock on the bottom. The CCS will control the source of releases of constituents listed in 35 I.A.C. § 845.60 and serve as the groundwater corrective action for the WAPS.

2.4.1 Proposed Corrective Action Construction

Corrective action construction will involve the construction of multiple elements of the CCS. These will include construction of the DCW, extending the final cover system over the DCW, and site restoration. No operations and maintenance activities are planned, outside of ongoing post-closure care activities, as the CCS will be a passive and low-maintenance structure.

Information associated with each of these construction elements of the CCS is provided below.

2.4.1.1 Deep Cutoff Wall Installation

The DCW that will encircle the entire perimeter of the former OWAP, with a total length of approximately 5,200 feet, will complement the existing site features and form a continuous containment system. The DCW will extend at least 1 foot into competent, low-permeability shale bedrock beneath the WAPS, which has a typical depth of approximately 90 feet below ground surface (bgs). The DCW will be constructed using either cement-bentonite or soil bentonite methods and will have a target hydraulic conductivity of 1×10^{-7} centimeters per second (cm/sec).

Construction of the DCW is expected to include the following tasks:

- The cutoff wall alignment will conflict with some perimeter areas of the WAPS' completed geosynthetic and soil final cover system. To allow for cutoff wall construction, the final cover system will be temporarily removed within the proposed limits of construction disturbance (limits of disturbance).
  - This will include stripping topsoil and cover soil from the geomembrane and temporarily stockpiling the materials for future final cover restoration.
  - Existing geosynthetic materials will be removed and disposed of at an off-site landfill.
  - Additional conflicting site infrastructure within the limits of disturbance including, but not limited to access roads, piezometers, monitoring wells, stormwater channels, stormwater letdown structures, and pressure relief vents, will also be abandoned and/or otherwise removed as part of the activities.
- A level working platform and temporary construction access roads will be constructed within the limits of disturbance to allow DCW construction equipment (*i.e.*, cranes, haul trucks, and light vehicles) access and traffic.
  - The working platform will require the grading of existing subsurface materials, which may include CCR and/or soils, in order to provide a level subgrade. This will likely require the excavation of materials in some areas and placement of fill in others.
  - The working platform will be designed to support surcharges induced from expected construction equipment, which may include large cranes.
  - The existing steel sheet pile wall located between the OWAP and OWPP will be removed. The wall will be either stored on-site, outside of the WAPS, or sold for off-site recycling or re-use.
- The DCW will be installed along its alignment through a process where the wall is excavated in vertical panels and the excavation is continually backfilled with either stabilizing slurry of a mixture of bentonite and subgrade soils.
  - A quality assurance and quality control (QA/QC) program will be implemented during construction of the DCW. This will include performing site-specific bench scale testing and mix design to develop an engineered wall backfill that meets the target wall hydraulic conductivity of 1×10^{-7} cm/sec prior to wall construction, collecting multiple samples of wall backfill material during construction for hydraulic conductivity and strength testing, and recording continuous logs of materials encountered during wall construction, including conditions at the tip of the DCW where it is keyed (*i.e.,* embedded) into competent shale bedrock. The purpose of this process is to verify that the as-constructed wall meets the design intent included within this Construction Permit Application.
  - 40,0000 to 60,000 CY of excavation spoils are expected to be generated during DCW installation. The spoils are expected to be predominantly non-CCR material and will be placed into off-road dump trucks and disposed of appropriately onsite. Spoils containing CCR materials will be placed into off-road dump trucks and disposed of in the East Ash Pond (EAP) as contouring fill in accordance with the submitted closure plan [14].

2.4.1.2 Final Cover System Extension

After the DCW is installed, the final cover system will be extended across the top of the DCW and restored to the original final closure design grades that are currently present at the WAPS. This will include placing a new low-permeability barrier layer within disturbed areas, welding it to the existing undamaged geomembrane barrier layer, extending the barrier layer over the top of the DCW, and terminating the geomembrane in a new anchor trench.

After the geomembrane is extended, a geotextile cushion will be extended over the top of the geomembrane barrier layer. Protective cover soil and a vegetative support layer will then be placed over the geotextile cushion. All final cover system materials and installation practices will be performed in accordance with the design and specifications that were prepared for the completed WAPS closure and will be consistent with the existing IEPA-approved closure plan [6]. QA/QC procedures will also be performed during final cover system extension where samples of geomembrane and cover soils are tested for conformance with the project specifications. All geomembrane seams and/or welds will also be subjected to QA/QC testing in accordance with the specifications utilized for the completed WAPS closure.

2.4.2 Site Restoration

After the final cover system extension is complete, site restoration activities will be initiated. This will include replacing any existing site infrastructure that was abandoned or otherwise removed from the limits of disturbance during CCS construction and establishing vegetation on disturbed areas.

2.5 Plans and Specifications

Section 845.220(a)(6): Plans and specifications fully describing the design, nature, function and interrelationship of each individual component of the facility.

Permit-level design plans and specifications for key construction materials are included within the Corrective Action Plan for the WAPS, provided in **Appendix G**. These plans were prepared in accordance with 35 I.A.C. § 845.670(a)(6) and are consistent with the narrative description provided in **Appendix G**, per 35 I.A.C. § 845.220(a)(5).

A permit-level evaluation of the stability of the WAPS perimeter dikes during installation of the DCW was prepared to support this Construction Permit Application. The stability assessment indicated that DCW installation activities using large construction equipment such as cranes is not expected to result in significant distress to the WAPS perimeter dikes, and that a safety factor of at least 1.30, in accordance with 845.460(a)(1), is expected to be maintained during DCW construction. This assessment and supporting geotechnical information is provided in **Appendix H**.

2.6 Groundwater Monitoring Program

Section 845.220(a)(7): A new groundwater monitoring program or any modification to an existing groundwater monitoring program that includes but is not limited to the following information:

A Corrective Action Groundwater Monitoring Plan is included in **Appendix B.1** of this application.

Section 845.220(a)(7)(A): A hydrogeologic site investigation meeting the requirements of Section 845.620, if applicable;

Hydrogeologic site investigations for the WAPS are provided in **Appendix B.2**.

Section 845.220(a)(7)(B): Design and construction plans of a groundwater monitoring system meeting the requirements of Section 845.630; and

Design and construction plans of a groundwater monitoring system as required by 35 I.A.C. § 845.630 are provided in the Operating and Closure and Post Closure Care Plan [6, 15]. The Corrective Action Groundwater Monitoring Plan (**Appendix B.1)** includes content requirements specific to 35 I.A.C. § 845.630 (Groundwater Monitoring System), 35 I.A.C. § 845.640 (Groundwater Sampling and Analysis), 35 I.A.C. § 845.650 (Groundwater Monitoring Program), and 35 I.A.C. § 845.680 (Implementation of the Corrective Action Plan) for the WAPS.

Section 845.220(a)(7)(C): A proposed groundwater sampling and analysis program that includes selection of the statistical procedures to be used for evaluating groundwater monitoring data (see Sections 845.640 and 845.650).

A groundwater sampling and analysis program that meets the requirements of 35 I.A.C. § 845.640 and 845.650 is provided in **Appendix B.1.**

2.7 Certification

Section 845.220(a)(8): The signature and seal of a qualified professional engineer

I, Lucas P. Carr, being a Registered Professional Engineer in good standing in the State of Illinois, do hereby certify, to the best of my knowledge, information, and belief, that the information contained in this Construction Permit Application has been prepared in accordance with the accepted practice of engineering. The content of this Construction Permit Application is not to be used other than for its intended purpose and meaning, or for extrapolations beyond the interpretations contained herein.

Lucas P. Carr
Printed name

5/6/2025
Signature Date

062-066694 IL 11/30/2025
Registration No. State Exp. Date

Affix Seal

2.8 Public Meeting Information

Section 845.220(a)(9): Certification that the owner or operator of the CCR surface impoundment completed the public notification and public meetings required under Section 845.240, a summary of issued raised by the public, a summary of any revisions, determinations, or other considerations made in response to those issues, and a list of interested persons in attendance who would like to be added to the Agency's listserv for the facility.

Certification that public notification and public meetings have been completed as required by 35 I.A.C. § 845.240 are provided in **Appendix I**.

2.9 Corrective Action Construction

Section 845.220(c)(1): Corrective action plan (see Section 845.670);

The Corrective Action Plan as required by 35 I.A.C. § 845.220(d)(4) is provided in **Appendix G**.

Section 845.220(c)(2): Groundwater modeling, including:

A. *The results of groundwater contaminant transport modeling and calculations showing how the corrective action will achieve compliance with the applicable groundwater standards;*
B. *All modeling inputs and assumptions;*
C. *Description of the fate and transport of contaminants with the selected corrective action over time; and*
D. *Capture zone modeling, if applicable.*

Groundwater modeling as required by 35 I.A.C. § 845.220(c)(2) is provided within Appendix B.1 of Corrective Action Alternatives Analysis Supporting Information Report, which is included as Appendix B of the Corrective Action Alternatives Analsyis, which is Appendix A of the Corrective Action Plan provided as **Appendix G** of this application.

Section 845.220(c)(3): Any necessary licenses and software needed to review and access both the models and the data contained within the models required by subsection (c)(2).

Consistent with previously submitted construction permit applications, electronic copies of the model files are provided within Appendix B.1 of the Corrective Action Alternatives Analysis Supporting Information Report. The Corrective Action Alternatives Analysis Supporting Information Report is included as Appendix B of the Corrective Action Alternatives Analysis, which is Appendix A of the Corrective Action Plan that is provided as **Appendix G** of this application. Publicly available software can be used to review and access the models and the data; no additional licenses or software are required.

Section 845.220(c)(4): Corrective action groundwater monitoring program, including identification of revisions to the groundwater monitoring system for corrective action.

The corrective action groundwater monitoring program as required by 35 I.A.C. § 845.220(c)(4) is provided in **Appendix B.1** of this application. The corrective action groundwater monitoring plan establishes how data will be collected, documented, and evaluated to assess remedy effectiveness for all currently documented and potential future releases from the WAPS. The presence of exceedances at the waste boundary will continue to be evaluated under the Operating Permit Groundwater Monitoring Plan (GMP) previously submitted to IEPA [15].

Section 845.220(c)(5): Any interim measures necessary to reduce the contaminants leaching from the CCR surface impoundment, and/or potential exposures to human or ecological receptors, including an analysis of the factors specified in Section 845.680(a)(3).

No interim measures are necessary or planned ahead of permit approval and completion of final design. The Corrective Action Plan, provided in **Appendix G**, provides an analysis of the factors specified in 35 I.A.C. § 845.680(a)(3).

3. ADDITIONAL INFORMATION

Certification that DMG will utilize contractors, subcontractors, and installers who are participants in an approved training program, in accordance with 415 Illinois Compiled Statutes (ILCS) 5/22.59(b)(4), is provided in **Appendix J**.

1. INTRODUCTION

1.1 Overview

In accordance with requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845: Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments, Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Corrective Action Groundwater Monitoring Plan (GMP) on behalf of Hennepin Power Plant (HPP), operated by Dynegy Midwest Generation, LLC (DMG). This GMP will apply specifically to the coal combustion residuals (CCR) Unit referred to as the West Ash Pond System (WAPS), CCR identification (ID) number (No.) 804, Illinois Environmental Protection Agency (IEPA) ID No. W1550100002-01 and W1550100002-03, and National Inventory of Dams (NID) No. IL50698. WAPS is comprised of two sub-units including the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). Both sub-units were originally constructed as a single unit with a single perimeter dike and subsequently internally divided into sub-units as part of operational practices. This document and all past engineering and hydrogeological studies consider the WAPS as a single CCR unit. The WAPS is a closed, unlined CCR SI that was previously used to manage CCR and non-CCR waste streams at the HPP.

This Corrective Action GMP includes 35 I.A.C. § 845 content requirements specific to 35 I.A.C. § 845.630 (*Groundwater Monitoring System*), 35 I.A.C. § 845.640 (*Groundwater Sampling and Analysis*), 35 I.A.C. § 845.650 (Groundwater Monitoring Program), and 35 I.A.C. § 845.680 (*Implementation of the Corrective Action Plan*) for the WAPS at the HPP.

A checklist in **Table 1-1** provides references to sections, tables, and figures within this document that meet the specific requirements of 35 I.A.C. § 845.630, 35 I.A.C. § 845.640, 35 I.A.C. § 845.650, and 35 I.A.C. § 845.680.

This Corrective Action GMP is included as Appendix B.1 to the Construction Permit Application for the HPP WAPS. The Corrective Action Plan proposes a continuous containment system which includes a deep cutoff wall combined with previously implemented source control (*i.e.,* closure) as the selected remedy for the WAPS. As described in the Corrective Action Plan, the proposed remedy meets the performance standards of 35 I.A.C. § 845.670(d) and addresses all current and potential future releases from the WAPS. Likewise, this Corrective Action GMP establishes how data will be collected, documented, and evaluated to assess remedy effectiveness for all currently documented and potential future releases from the WAPS[1] per the process outlined in **Figure 1-1**.

Adaptive site management strategies are an integral part of corrective action groundwater monitoring. The adaptive site management approach consistent with National Research Council, Interstate Technology & Regulatory Council and United States Environmental Protection Agency (USEPA) methodologies will allow timely incorporation of new site information throughout corrective action to ensure the achievement of the groundwater protection standard (GWPS). The adaptive site management approach expedites progress toward meeting the GWPS while acknowledging uncertainties, such as the persistence of current groundwater flow directions and potential related changes in geochemical conditions. The structured decision-making process

[1] The presence of exceedances at the waste boundary will continue to be evaluated under the Operating permit GMP previously submitted to IEPA [4].

proposed in this Corrective Action GMP includes specific metrics used to evaluate remedy progress, criteria which would trigger adaptive management evaluation, and options for those management actions.

1.2 Site Location and Background

The HPP is an approximately 504-acre property consisting of 19 parcels positioned adjacent to the Illinois River, including a retired coal-fired power plant, CCR landfill and SIs, and farmland. The HPP is located in the northwest quarter of Section 26, Township 33 North, Range 2 West, Putnam County, Illinois and approximately 3 miles north-northeast of the Village of Hennepin (**Figure 1-2**).

The HPP construction history includes construction of Unit 1 in 1953 and Unit 2 in 1969, with capacities of 70 megawatts (MW) and 210 MW, respectively. The plant initially burned high-sulfur Illinois coal and switched to sub-bituminous Powder River Basin coal in 1999 [1]. The HPP ceased operations in 2019 when the power plant was retired.

The WAPS is one of three CCR units at the HPP regulated under 35 I.A.C. § 845. The other two CCR units regulated under 35 I.A.C. § 845 (Ash Pond Number [No.] 2 and No. 4 multi-unit [AP2/AP4] and the East Ash Pond) are located adjacent to each other and the Landfill, east of the HPP. The WAPS is located west of the HPP. Areas surrounding the WAPS include agricultural land, with scattered groupings or rows of trees to the southeast, and low-lying floodplains of the Donnelley Wildlife Management Area to the southwest and west. The WAPS and surrounding properties are shown on **Figure 1-3**.

1.3 Conceptual Site Model

Significant site investigation has been completed at the HPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the WAPS has been well characterized and detailed in the Hydrogeologic Site Characterization Report (HCR) [2] included in the Operating Permit Application[2] and the Nature and Extent Report [3][3]. A conceptual site model (CSM) has been developed and is discussed below.

The WAPS is characterized by two hydrostratigraphic units. The units, listed from surface downward, are summarized as follows:

- **Uppermost Aquifer (UA)**: Includes the Cahokia Alluvium which consists of fine-grained river deposits comprised of silts and clays (upper UA), fine-medium sands (middle UA), and highly permeable glacial outwash sands and gravels of the Henry Formation (lower UA). The UA contains variable amounts of cobbles and boulders within a sand and gravel matrix. Both the prevalence and size of the cobbles and boulders increase with depth.

- **Bedrock Confining Unit**: Comprised of interbedded layers of shales with thin limestone, sandstone, and coal beds. Representative hydraulic conductivity for shale ranges from 5×10^{-6} to 5×10^{-10} centimeters per second (cm/s) and this unit defines the lower boundary

[2] The HCR was previously included as Attachment H of the Hennepin Power Plant Old West Ash Pond No. 1 and No. 3 and Old West Polishing Pond Operating Permit Application, submitted to IEPA on October 25, 2021.
[3] The Nature and Extent Report was previously submitted to IEPA [3] and is provided with updates as Appendix D of the Corrective Action Alternatives Assessment (CAAA). The CAAA serves as Appendix A to the Corrective Action Plan to which this report is attached.

of the UA. Borings along the perimeter of the nearby East Ash Pond System confirm the presence of shale bedrock between elevations ranging from 399.2 to 410.2 feet [2].

The direction of groundwater flow and hydraulic gradient within the UA varies with the elevation of the Illinois River. During normal river stage the direction of groundwater flow is most often toward the river, but comparison of groundwater and river elevation data indicate reversals in this flow direction during times of high river elevations. The relative duration of these events is short, which leads to the determination of a predominant groundwater flow direction toward the river Flow directions are generally consistent between seasons. Groundwater elevations and contours for the May 30, 2023 groundwater monitoring event (Event 1 [E001]) are presented in **Figure 1-4**.

1.4 Groundwater Quality

Groundwater monitoring in accordance with the proposed Operating GMP and sampling methodologies provided in the operating permit application for groundwater compliance at the WAPS began in the second quarter of 2023 [4]. The proposed compliance monitoring wells yield groundwater samples that represent the quality of downgradient groundwater at the CCR boundary (as required in 35 I.A.C. § 845.630(a)(2)).

The E001 quarterly groundwater monitoring event was completed on June 1, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), and the statistical analysis plan submitted with the operating permit application (Appendix A of the Groundwater Monitoring Plan) constituent concentrations observed at compliance wells were evaluated for compliance the GWPSs summarized in 35 I.A.C. § 845.600 to determine exceedances[4] of the GWPS. The statistical determination identified the following GWPS exceedances at compliance groundwater monitoring wells [5]:

- Arsenic at wells 21R and 51
- Boron at wells 21R, 22, 23, and 35
- Cadmium at well 22
- Sulfate at wells 23 and 35

Pursuant to 35 I.A.C. § 845.650(e), an Alternative Source Demonstration (ASD) presented evidence demonstrating that sources other than the WAPS were the cause of the cadmium GWPS exceedance at well 22 [6], and the ASD was subsequently approved by the IEPA [7].

Subsequent compliance sampling events (following E001) were evaluated for exceedances of the GWPS as described in 35 I.A.C. § 845.600 [8, 9, 10, 11, 12, 13]. Exceedances identified during the subsequent events were consistent with those listed above. In addition to the exceedances listed above, the following exceedances were identified:

- Lithium at well 22
- Total dissolved solids (TDS) at well 35

[4] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of DMG's operating permit application for the HPP WAPS. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, DMG has not identified any actual exceedances.

In accordance with 35 I.A.C. § 845.660, a Corrective Measures Assessment was developed to address current and potential future GWPS exceedances originating from the WAPS, exclusive of the cadmium exceedance addressed in the ASD, and was submitted to IEPA on May 8, 2024 [14]. The 35 I.A.C. § 845.650 groundwater monitoring requirements will continue to ensure that there will be timely detection of changes in groundwater quality during the stay. The selected remedy will meet the performance standards of 35 I.A.C. § 845.670(d) and once implemented and completed, the selected remedy presented in the Corrective Action Plan will attain the GWPSs.

1.5 Supplemental Site Investigation

A limited investigation was conducted in 2024 in accordance with 35 I.A.C. § 845.650 to assess the hydraulic conductivity of the bedrock in preparation for design of the proposed bedrock cutoff wall. Three borings were advanced along the perimeter of the HPP WAPS through unconsolidated materials and into competent bedrock. Soil lithology was logged continuously from borings completed at these locations, and packer testing was conducted on select intervals from each boring to evaluate ranges in bedrock hydraulic conductivities. During the bedrock investigation, one aquifer solids sample was collected to further assess nature, degree, and extent of arsenic groundwater impacts downgradient of the HEN WAPS [15].

2. CORRECTIVE ACTION GROUNDWATER MONITORING PLAN

This Corrective Action GMP is being provided to propose a groundwater monitoring program specific to the WAPS that will comply with 35 I.A.C. § 845.680. The Corrective Action GMP will monitor and evaluate groundwater quality specifically to document the effectiveness of the corrective action remedy. The groundwater monitoring program will include sampling and analysis procedures that are consistent and that provide an accurate representation of groundwater quality.

2.1 Corrective Action Groundwater Monitoring Program and Parameters

2.1.1 35 I.A.C. § 845 Corrective Action Groundwater Monitoring

The proposed 35 I.A.C. § 845 corrective action monitoring well network will consist of eight wells to document the effectiveness of the corrective action remedy and ultimately demonstrate compliance with GWPSs (**Figure 2-1**). The wells included in the corrective action monitoring well network include select compliance monitoring wells from the Operating GMP network (*e.g.*, those with previously reported exceedances of the GWPS) (**Section 1.4**).

As appropriate to meet the corrective action monitoring objectives and evaluate the effectiveness of the corrective action remedy (as described in **Section 3**), the corrective action monitoring program involves assigning each well to a monitoring category or purpose (**Table 2-1**). These monitoring categories include:

- **Inside Plume**: monitoring wells installed at the CCR boundary with GWPS exceedances.
- **Plume Definition**: wells located along the lateral or vertical boundary of the plume.

A summary of the well locations and associated purpose as it relates to the above categories is presented in **Table 2-1** and **Figure 2-1**. Monitoring well depths and construction details are listed in **Table 2-2**, and boring logs and monitoring well construction forms are provided in **Appendix A**. Groundwater samples will be collected and analyzed for the laboratory and field parameters in **Table 2-3**. Laboratory parameters include major ions for evaluating groundwater chemistry and constituents of concern (COCs) (*i.e.*, reported exceedances in accordance with the Operating GMP) the Corrective Action is intended to address. Sampling to evaluate corrective action effectiveness will begin the quarter after the corrective action remedy is implemented and commissioned.

2.2 Sampling Schedule

All wells in the corrective action GMP network, as presented in **Table 2-1**, will be sampled quarterly to provide a complete picture of corrective action effectiveness. Groundwater elevations will be determined at the time of sample collection from each well. Sampling will end in accordance with 35 I.A.C. § 845.680(c), when compliance with the GWPS has been demonstrated "at all points within the plume of contamination that lies beyond the waste boundary […] for a period of three consecutive years" (details in **Section 3.3**).

Consistent with 35 I.A.C. § 845.650(b)(4), quarterly sampling may be reduced to a semiannual frequency with IEPA approval after completion of five years of monitoring. A request for reduced sampling frequency will include a demonstration that corrective action monitoring effectiveness

will not be compromised; sufficient data has been collected to evaluate ongoing remedy effectiveness; and existing data show trends consistent with anticipated remedy performance (details in **Section 3.1**).

2.3 Groundwater Sample Collection

Groundwater sampling procedures have been developed and the collection of groundwater samples is being implemented to meet the requirements of 35 I.A.C. § 845.640. In addition to groundwater well samples, quality assurance samples will be collected as described in **Section 2.5** (**Table 2-3**). Groundwater samples will be collected and analyzed in accordance with the Multi-Site Sampling and Analysis Plan [16][5].

2.4 Laboratory Analysis

Laboratory analysis will be performed consistent with the requirements of 35 I.A.C. § 845.640(j) by a state-certified laboratory using methods approved by IEPA and USEPA. Laboratory methods may be modified based on laboratory equipment availability or procedures, but the Reporting Limit (RL) for all parameters analyzed, regardless of method, will be lower than the applicable groundwater quality standard [17]. Concentrations lower than the RL will be reported as less than the RL.

2.5 Quality Assurance Program

Consistent with the requirements of 35 I.A.C. § 845.640(a)(5), the sampling and analysis program includes procedures and techniques for quality assurance/quality control (QA/QC)[5]. Additional quality assurance samples to be collected will include the following:

- Field duplicates will be collected at a frequency of one per group of ten or fewer investigative water samples.
- One equipment blank sample will be collected and analyzed for each day of sampling. If dedicated sampling equipment is used, then equipment blank samples will not be collected.
- The duplicate and equipment blank quality assurance samples will be supplemented by the laboratory QA/QC program, which typically includes:
  - Regular generation of instrument calibration curves to assure instrument reliability
  - Laboratory control samples and/or quality control check standards that have been spiked, and analyses to monitor the performance of the analytical method
  - Matrix spike/matrix spike duplicate analyses to determine percent recoveries and relative percent differences for each of the parameters detected
  - Analysis of replicate samples to check the precision of the instrumentation and/or methodology employed for all analytical methods
  - Analysis of method blanks to assure that the system is free of contamination

Water quality meters used to measure pH and turbidity will be calibrated according to manufacturer's specifications. At a minimum, it is recommended that calibration of pH occur daily prior to sampling and checked for accuracy at the end of each day. Unusual or suspect pH

[5] The Multi-Site Sampling and Analysis Plan and Multi-Site Quality Assurance Project plan are living documents which are subject to routine evaluation and updates in accordance with USEPA recommended best practices [24, 25].

measurements during sampling events will be flagged, evaluated, and additional calibration may be performed throughout the sampling events. Turbidity meters will be checked daily, prior to and following sampling. Unusual measurements or erratic meter performance will be flagged and evaluated for overall effects on the data prior to reporting.

2.6 Groundwater Monitoring Well Maintenance Plan

Consistent with the requirements of 35 I.A.C. § 845.630(e)(2), maintenance will be performed according to the Multi-Site Sampling and Analysis Plan [16] as needed to assure that the monitoring wells provide representative groundwater samples. Monitoring wells will be inspected during each groundwater sampling event; inspections will consist of the following:

- Visual inspection, clearing of vegetation, replacement of markers, and painting of protective casings as needed to assure that monitoring wells are clearly marked and accessible
- Visual inspection and repair or replacement of well aprons as needed to assure that they are intact, drain water away from the well, and have not heaved
- Visual inspection and repair or replacement of protective casings as needed to assure that they are undamaged, and that locks are present and functional
- Checks to assure that well caps are intact and vented, unless in flood-prone areas in which case caps will not be vented
- Routine measurement of monitoring well depths to determine the degree of siltation within the wells. Wells will be redeveloped as needed to remove siltation from the screened interval if it impedes flow of water into the well
- Checks to assure that wells are clear of internal obstructions, and flow freely

If wells are damaged or become otherwise inoperable, they will be replaced by wells screened at the same elevation and as close to the original well as possible (ideally within 10 feet) and notification will be provided to IEPA. If a replacement well cannot be installed within approximately 10 feet of the original well location, notification will be sent to IEPA and a monitoring well will be installed as close as possible to the original monitoring well and given a new well identification number. Any well replacement activities will also be documented in the Annual Groundwater Monitoring and Corrective Action Report.

2.7 Statistical Analysis

A Multi-Site Statistical Analysis Plan (StAP) (**Appendix B**), has been developed to summarize the statistical procedures that will be used to evaluate the groundwater results.

2.8 Data Reporting

Groundwater monitoring and analysis completed in accordance with 35 I.A.C. § 845 under an approved monitoring program will be reported to IEPA annually by January 31 as required by I.A.C. § 845.550, for data collected the preceding year. The Annual Groundwater Monitoring and Correct Action Report will include the status of the groundwater monitoring and Corrective Action Plan for the WAPS in addition to other requirements detailed in 35 I.A.C. § 845.610(e).

2.9 Compliance with Applicable Groundwater Protection Standards

As provided in 35 I.A.C. § 845.680(c)(2), corrective action is considered complete when compliance with the GWPS has been achieved by demonstrating that concentration of

constituents listed in 35 I.A.C. § 845.600 have not exceeded the GWPSs for a period of three consecutive years, using the statistical procedures and performance standards in 35 I.A.C. § 845.640(f) and (g).

Attainment of GWPSs and conclusion of corrective action monitoring is discussed below in **Section 3.3**.

If a new exceedance is determined during monitoring under the Operating GMP, the Corrective Action groundwater monitoring program will be evaluated for monitoring of additional locations and/or constituents using the adaptive site management methods presented herein.

3. EFFECTIVENESS OF THE CORRECTIVE ACTION REMEDY

The methods for evaluating the effectiveness of the corrective action remedy described in this section are based on the following guidance documents:

- "Methods for Evaluating the Attainment of Cleanup Standards Volume 2: Groundwater," Office of Policy, Planning, and Evaluation, 1992 [18].
- "Groundwater Remedy Completion Strategy: Moving Forward with the End in Mind," Office of Solid Waste and Emergency Response, 2014 [19].
- "Adaptive Site Management – A Framework for Implementing Adaptive Management at Contaminated Sediment Superfund Sites," USEPA, Office of Superfund Remediation and Technology Innovation, 2022 [20].
- "Environmental Cleanup Best Management Practices: Effective Use of the Project Life Cycle Conceptual Site Model," USEPA Office of Solid Waste and Emergency Response, 2011 [21].

Evaluation of corrective action remedy effectiveness will occur in three phases (**Figure 3-1**): remedy progress evaluation, stability evaluation, and attainment evaluation [18].

1. Remedy progress evaluation occurs after implementation of corrective actions to assesses if the remedy is functioning as anticipated.
2. The stability evaluation, which assesses if a new post-treatment steady state in the groundwater has been reached.
3. Attainment evaluation occurs after a new steady state has been achieved and assesses if COC concentrations are below the GWPS.

COCs are parameters with exceedances of the GWPS to be addressed by the Corrective Action Plan. Corrective action monitoring at HEN WAPS includes the following COC parameters:

- Arsenic, boron, lithium, sulfate, and TDS

The effectiveness of the remedy at each phase is evaluated using performance metrics designed to assess the goals of that phase. Performance metrics answer questions designed to evaluate multiple aspects of remedy effectiveness with the ultimate goal of holistically guiding management decisions [19]. These metrics may be evaluated using qualitative (subject to expert judgement) or quantitative (numerical outcomes) methods.

This section details the goals and performance metrics of each phase of remedy evaluation. Within each phase, the well groups described in **Section 2.1** have distinct applicable metrics and/or potential management actions consistent with the role of that well group within the corrective action monitoring framework. The remedy evaluation metrics documented here are specific to wells within the Corrective Action monitoring program.

3.1 Remedy Progress Evaluation

The goal of remedy process evaluation is to determine if a groundwater remedy is on track to achieve cleanup standards within the proposed time frame and to inform adaptive management decisions if performance metrics are not achieved. Evaluation of remedy progress includes evaluating the response of COCs in individual monitoring wells and in the plume as a whole. Remedy progress is evaluated using performance metrics as described below. **Table 3-1** details

the questions used to assess remedy progress and metrics which would trigger additional evaluation of adaptive site management options. **Figure 3-2** presents an outline of the decision-making process regarding adaptive management actions (the first step of which is assessing remedy progress per **Table 3-1**).

Documentation of remedy progress metrics will be provided in the Annual Groundwater Monitoring and Corrective Action Report (**Section 2.8**) beginning after the second year of data collection: a minimum of eight data points is required to complete meaningful statistical analysis required for evaluation of the remedy progress metrics, which will be available after two years of quarterly sampling. Per USEPA guidance [19], a thorough review of corrective action progress and remedy effectiveness will be conducted every five years. A Five-Year Annual Groundwater Monitoring and Corrective Action Report will evaluate the comprehensive data set and, if triggered by the results of the remedy progress evaluation metrics (**Table 3-1**), evaluate whether adaptive management actions are needed (**Figure 3-2**). The five-year time frame allows adaptive management decisions to be based on a robust data sufficient to complete meaningful statistical analysis while remaining responsive to changing site conditions [19]. The remedy progress evaluation metrics and triggers for additional evaluation are described below.

3.1.1 Comparison to Groundwater Protection Standard

The plume wells in this monitoring plan were defined based on exceedances of the GWPS. The question posed to evaluate whether exceedances of the GWPS occur, and associated method of evaluation is (**Table 3-1**):

- Are COC concentrations greater than the GWPS? – Compare data points or summary statistics to site-specific GWPS values.

COC concentrations below the GWPS in plume wells may indicate that remedial actions are approaching completion and that moving to the next phase of remedy effectiveness evaluation may be warranted (see **Section 3.2**). Persistence of COC concentrations above the GWPS in Plume Definition wells may indicate that the plume is no longer properly delineated. Therefore, the trigger criterion for further evaluation is a central tendency measure of the last eight data points exceeding the GWPS.

3.1.2 Agreement with Groundwater Model

A groundwater flow and transport model[6] was used to compare the anticipated time to reach the GWPS for the different corrective actions considered at the WAPS.

The question posed to evaluate agreement of corrective action remedy progress with the groundwater model results is provided in **Table 3-1** and summarized below:

- Are concentrations of COCs at individual wells consistent with modeling expectations? – Evaluate if the observed results track with the predicted results in general direction and magnitude using expert professional judgement.

Only plume and Plume Definition wells included in the flow and transport model are evaluated according to this metric. Trigger criteria for additional adaptive site management evaluation include monitoring results failing to follow the general magnitude and direction of groundwater

[6] The Groundwater Modeling Technical Memorandum is included as an attachment to the Corrective Actions Alternative Analysis presented as part of the Corrective Action Plan.

model results at one or more locations. It is acceptable to conclude that if no further adaptive site management evaluation is triggered if future observations do not precisely match modeled results on an individual well basis if the direction of remedy progress is adequate.

3.1.3 Trend Analysis

Evaluation of COC trends in wells both within and outside of the plume is a major component of remedy progress evaluations [18, 19]. Decreasing COC concentrations within the groundwater plume provides critical support for remedy effectiveness evaluations. Changing concentrations in wells defining the plume may indicate unanticipated plume migration or a need for better Plume Definition. Both short-term and long-term trends are important to evaluate remedy performance [18]. All trend analyses are performed in accordance with the Multi-Site StAP (**Appendix B**) and the USEPA Unified Guidance for groundwater statistics [22].

The questions posed to evaluate if COC concentrations are decreasing in Inside Plume wells and the associated methods for evaluation are provided in **Table 3-1** and summarized as follows:

- Are average plume COC concentrations decreasing? – Evaluate trend based on quarterly average of COC concentrations of Inside Plume wells, both for the last eight sampling events and since corrective action was initiated.

The questions posed to evaluate if COC concentrations are changing in Inside Plume wells and Plume Definition wells and the associated methods for evaluation are provided in **Table 3-1** and summarized below:

- Are concentrations of COCs at individual wells changing? – Evaluate trend of COC concentrations, both for the last eight sampling events and since corrective action was initiated.

The goal of the corrective action is to reduce COC concentrations in the groundwater. Therefore, trigger criteria have been established for the two types of corrective action monitoring wells as follows:

- Inside Plume well triggers for adaptive site management evaluation are based on no decreasing trend in COC concentrations (short-term or long-term).
- Plume Definition well triggers are based on increasing COC concentrations, which may indicate improper delineation of the plume. Therefore, the trigger criterion for adaptive site management evaluation at Plume Definition wells is increasing short- or long-term trend.

3.1.4 Adaptive Management Actions

The goal of adaptive management actions is to understand why performance metrics are not met and, if the remedy is found to be unsuccessful in meeting remediation goals, drive supplemental corrective actions or, in extreme cases, re-evaluation of remedy selection. This section describes in greater detail the steps in the flow chart presented in **Figure 3-2** (adapted from Figure 2 in [19]).

As the remedy progress evaluation metrics are evaluated annually, failure to meet the metrics (as described in **Table 3-1**) leads to further action. If the data available at the time of the Five-Year Review are anticipated to be inadequate for determining the need for adaptive site

management actions, additional data may be collected before the Five-Year Review including collecting samples from additional wells or measuring additional parameters.

If the remedy progress is not found to be adequate during the Five-Year Review, the most critical question is whether or not the remedy is likely to achieve the GWPS in a reasonable time frame. This may be evaluated using methods such as regression analysis or analysis of groundwater flow. If the remedy progress is not judged to be adequate but the remedy is likely to achieve the GWPS in a reasonable time frame, the CSM or the groundwater model may require updating to reflect evolving field conditions[7]. Additional data collected may also suggest ways to optimize the monitoring network or performance metrics [19].

If the remedy does not appear likely to achieve the GWPS in a reasonable time frame, it may be due to changing hydrogeochemical dynamics within the plume or an additional source of COCs not accounted for in the CSM. If available data suggests either occurrence, the Five-Year Review will describe additional activities planned to investigate if the existing remedy is still a viable option for attaining the GWPS. If the remedy is still viable, an update to the CSM and groundwater model is likely required [19, 21] and will be conducted after additional investigation is completed.

If the remedy does not appear likely to achieve the GWPS in a reasonable time frame, the plume is appropriately delineated, there is no alternative source of COCs not accounted for in the CSM, and the plume is appropriately delineated; or if the investigation into the hydrogeochemical changes or alternative source of COCs determines that the remedial action is no longer solely viable as a corrective action, an evaluation of additional remedial actions will be initiated.

If the remedy progress evaluation metrics indicate that concentrations across the monitoring network are below the GWPS, the remedy progress phase may be considered complete, and the monitoring program may move to the Stability Evaluation phase (see **Section 3.2**).

3.2 Stability Evaluation

Evaluation of groundwater stability reflects the idea that implementation of a remedy will, by necessity, cause changes to the physical and chemical environment of the groundwater. Before assessing if compliance with the GWPS has been attained (Section 3.3), any transient effects of treatment on the groundwater (e.g., rebounding concentrations) should be allowed to dissipate [18]. Stability is evaluated to assess if a new stable equilibrium has been reached after final closure has been implemented. Stability is achieved when groundwater elevations are stable (accounting for seasonal variability); average COC concentrations are stable across all wells; and COC concentrations are stable at each well.

Trends in groundwater elevation and COC concentrations at each plume well will be evaluated using the most recent eight data points (*i.e.*, two years of data when sampling quarterly) according to methods presented in the Multi-Site StAP (**Appendix B**). This metric is met for a plume well when there is no statistically significant trend for three consecutive years.

Plume COC concentrations will be evaluated for trend using the most recent eight data points, with the average concentration across plume wells per sampling event considered as one data

[7] As stated in Section 1.4.1 of the Corrective Action Plan, "Estimated times to reach GWPS will be periodically reviewed and updated based on observed corrective action performance via an adaptive site management strategy."

point, according to methods presented in the Multi-Site StAP (**Appendix B**). This metric is met when there is no statistically significant trend in groundwater elevation or COC concentrations.

3.3 Attainment Evaluation and Conclusion of Corrective Action Monitoring

The ultimate goal of groundwater corrective action is to attain compliance with the GWPS for each COC in Inside Plume wells. After stability has been achieved per the metrics discussed in **Section 3.2**, attainment evaluation will begin. Per 35 I.A.C. § 845.680(c), corrective action is considered complete when compliance with the GWPS has been demonstrated "at all points within the plume of contamination that lies beyond the waste boundary […] for a period of three consecutive years". Attainment of the GWPS will be evaluated in accordance with the Multi-Site StAP (**Appendix B**). Corrective Action monitoring is considered complete for the site when COCs in the corrective action monitoring well network do not exceed the GWPS for three years.

Turbidity [9]	SM 2130 B	8	NA	NA	NA	NA	8	flow-through cell or hand-held turbidity meter	NA	none	immediately

[O: JRK 11/26/2024; C: CJC 12/10/2024]

Notes:
[1] Analytical method numbers are from SW-846 unless otherwise indicated. Analytical methods may be updated with more recent versions as appropriate.
[2] Field duplicates will be collected at a frequency of one per group of 10 or fewer investigative water samples. Field duplicates will not be collected for radium analysis.
[3] Field blanks will be collected at the discretion of the project manager; Equipment blanks will be collected at a rate of 1 per sampling event if non-dedicated equipment is used.
[4] Matrix Spike/Matrix Spike Duplicate (MS/MSD) samples will be collected at a frequency of one per group of 20 or fewer investigative water samples per CCR unit/multi-unit. Additional volume to be determined by laboratory.
[5] Sample volume is estimated and will be determined by the laboratory.
[6] Determined by reported exceedances under the Operating Groundwater Monitoring Plan
[7] Metals may be analyzed via USEPA methods 6010 or 6020 depending on laboratory instrument availability.
[8] Parameter collected for quality assurance and quality control for field sampling purposes only; not required to be collected or reported under 35 IAC § 845; collection of parameter may be discontinued without notification.
[9] If turbidity exceeds 10 NTU, a duplicate sample filtered through a 0.45 micron filter may be collected for metals analysis in addition to the unfiltered sample. Both samples would be submitted for analysis.
< = less than
°C = degrees Celsius
HNO_3 = nitric acid
mL = milliliter
NA = not applicable
NTU = nephelometric turbidity unit

Table 3-1. Adaptive Site Management Metrics and Trigger Criteria
Corrective Action Groundwater Monitoring Plan
Hennepin Power Plant
West Ash Pond System
Hennepin, IL

QUESTION	Are COC concentrations greater than the GWPS?		Are concentrations of COCs at individual wells consistent with modeling expectations?[a]		Are the average COC concentrations decreasing?	Are concentrations of COCs at individual wells changing?	Adaptive Site Management Outcome
EVALUATION[b]	Compare data points or summary statistics to site-specific GWPS		Do the observed results track with the predicted results in general direction and magnitude? (Professional judgement)		Evaluate trend on quarterly average of well concentrations, both for last 8 data points and since corrective action initiated or closure completed	Evaluate trend of COCs at each well, both for last 8 data points and since corrective action initiated	
Inside Plume	Central tendency concentration of last eight data points above the GWPS	**AND**	Results inconsistent with model	**AND MORE THAN ONE OF**	Neither trend decreasing	Neither trend decreasing	**Additional Evaluation Triggered (See Figure 3-2)**
Lateral/Vertical Plume Definition	Central tendency concentration of last eight data points above the GWPS		Results inconsistent with model		--	Either trend increasing	

[O: CJC 10/23/2024; C: AOC 10/30/2024]

Notes:
a. Only applies to wells included in the flow and transport model
b. To be documented in Annual Monitoring and Corrective Action Reports
-- = No relevant trigger criteria
COC = constituent of concern
GWPS = groundwater protection standard

LICENSED PROFESSIONAL CERTIFICATIONS

This certification is based on the description of the statistical methods selected to evaluate groundwater as presented in the following 35 I.A.C. § 845 Multi-Site Statistical Analysis Plan. The procedures described in the plan will be used to establish background conditions and implement compliance and corrective action monitoring as necessary and required by 35 I.A.C. § 845.640, § 845.650, and § 845.680. The 35 I.A.C. § 845 Multi-Site Statistical Analysis Plan was prepared in accordance with the requirements of 35 I.A.C. § 845.640(f), with reference to the acceptable statistical procedures provided in the United States Environmental Protection Agency (USEPA)'s *Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Unified Guidance* (*Unified Guidance,* USEPA 2009), and is intended to provide a logical process and framework for conducting the statistical analysis of the data obtained during groundwater monitoring. In accordance with 35 I.A.C. § 845.640(f)(1), the statistical method chosen for analysis of background groundwater quality is the tolerance interval procedure for each constituent listed in 35 I.A.C. § 845.600(a)(1) at this CCR unit per 35 I.A.C. § 845.640(f)(1)(C). Groundwater Protection Standards (GWPS) will be established in accordance with 35 I.A.C. § 845.600(a) (greater of the background concentration or numerical limit specified in 35 I.A.C. § 845.600(a)(1)). The GWPS will be compared to the appropriate confidence interval for the observed concentrations for each constituent in each compliance well. Consistent with the *Unified Guidance*, the same general statistical method of confidence interval testing against a fixed GWPS is recommended in compliance and corrective action programs. Confidence intervals provide a flexible and statistically accurate method to test how a parameter estimated from a single sample compares to a fixed numerical limit. Confidence intervals explicitly account for variation and uncertainty in the sample data used to construct them.

Description of the statistical methods chosen for analysis of groundwater monitoring data and application of these methods for determining exceedances of the GWPS identified in 35 I.A.C. § 845.600(a) is provided in this 35 I.A.C. § 845 Multi-Site Statistical Analysis Plan.

35 I.A.C. § 845.640 Statistical Analysis (PE)

I, Eric J. Tlachac, a qualified professional engineer in good standing in the State of Illinois, certify that the statistical methods summarized above and described in this document (35 I.A.C. § 845 Multi-Site Statistical Analysis Plan) are appropriate for evaluating the groundwater monitoring data collected as described in the attached document and are in substantial compliance with 35 I.A.C. § 845.640.

1. INTRODUCTION

In April 2021, the Illinois Environmental Protection Agency (IEPA) issued a final rule for the regulation and management of coal combustion residuals (CCR) in surface impoundments (SIs) under the Standards for the Disposal of CCR in Surface Impoundments: Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845. Facilities regulated under 35 I.A.C. § 845 are required to develop and sample a groundwater monitoring well system to evaluate whether impounded CCR materials are impacting groundwater quality. The groundwater quality evaluation must include certification from a qualified professional engineer that the selected statistical method is appropriate for evaluating groundwater monitoring data for the CCR surface impoundment. The procedures described in the evaluation will be used to establish background conditions and implement Compliance and Corrective Action Monitoring as necessary and required by 35 I.A.C. § 845.640, § 845.650, § 845.680, and § 845.780. This Statistical Analysis Plan was prepared in accordance with the requirements of 35 I.A.C. § 845.640(f), with reference to the acceptable statistical procedures provided in United States Environmental Protection Agency's (USEPA's) Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Unified Guidance (Unified Guidance) (USEPA, 2009).[1]

1.1 Statistical Analysis Objectives

This Multi-Site Statistical Analysis Plan provides a framework for conducting the statistical analyses of groundwater data collected during operation, post-closure care, and corrective action monitoring (if required). This Multi-Site Statistical Analysis Plan does not include procedures for groundwater sample collection and analysis conducted in accordance with the Multi-Site Sampling and Analysis Plan (SAP; Ramboll, 2022) or data quality evaluation conducted in accordance with the Multi-Site Quality Assurance Project Plan (QAPP; Ramboll, 2022).[2]

1.2 Statistical Analysis Plan Approach

The analyses described in this document are intended to support monitoring programs described in detail in the CCR unit-specific Operating Permit Groundwater Monitoring Plans (GMPs), Closure Construction Permit GMPs, and Corrective Action GMPs. When necessary and contingent upon equivalent statistical power, an alternative test consistent with the performance standards in 35 I.A.C. § 845.640(g), not included in this Statistical Analysis Plan, may be chosen due to site-specific data requirements.

35 I.A.C. § 845 outlines three phases of groundwater monitoring:

- Baseline Monitoring in accordance with 35 I.A.C. § 845.650(b)(1)
- Compliance Monitoring in accordance with 35 I.A.C. § 845.650 and 35 I.A.C. § 845.780(b)
- Corrective Action Monitoring in accordance with 35 I.A.C. § 845.680(a)

Each phase of the groundwater monitoring program requires specific statistical procedures to accomplish the intended purpose. During the first phase, background groundwater quality will be established, utilizing upgradient and background wells. Compliance Monitoring, which

[1] Despite being currently archived on USEPA's website, the Unified Guidance remains a valid reference for developing a statistical analysis plan (personal communication with Alison O'Connor, February 11, 2025).

[2] The Multi-Site Sampling and Analysis Plan and Multi-Site Quality Assurance Project plan are living documents which are subject to routine evaluation and updates in accordance with USEPA recommended best practices (USEPA 2020; USEPA 2023).

encompasses data collection and statistical evaluation conducted during unit operation and the post-closure care period, will then evaluate whether exceedances occur for 20 required constituents (per 35 I.A.C. § 845.600(a)(1)) relative to the groundwater protection standard (GWPS) established by 35 I.A.C. § 845.600. Corrective Action Monitoring evaluates remedy progress and completion and will be initiated upon implementation of the Corrective Action GMP.

2. GROUNDWATER DATA EVALUATION AND STATISTICAL ASSUMPTIONS

The following subsections outline the statistical tests and procedures utilized to evaluate data collected for consistency with statistical assumptions and evaluate data distribution. These methods may be used in any phase of groundwater monitoring.

2.1 Sample Independence

Independence of sample results is a major assumption for most statistical analyses. To ensure physical independence of groundwater sampling results, the minimum time between sampling events must be longer than the time required for groundwater to move through the monitoring well. Therefore, the minimum time interval between sampling events is a function of the groundwater velocity and well bore volume (diameter of the well and surrounding filter pack). The sampling schedules for Baseline Monitoring, Compliance Monitoring, and Corrective Action Monitoring are specified in 35 I.A.C. § 845 and may conflict with the statistical assumption of independence of sample results.

2.2 Non-Detect Data Processing

Groundwater sample analysis results below the reporting limit (RL), also referred to as the practical quantitation limit (PQL), will not be used in statistical calculations due to the inherent uncertainty in results that are estimated between the method detection limit (MDL) and RL/PQL, and error assumptions inherent to the statistical calculations. Results below the RL/PQL will be considered non-detect data. For statistical characterization evaluations (*e.g.*, distribution testing, and trend analysis), non-detects were replaced with the half of the RL for the analysis. For statistical test procedures that involve the calculation of a mean and standard deviation (as described in **Section 3**):

- If the frequency of non-detect data are less than or equal to 15 percent (%), half of the RL will be substituted for these data.
- If the non-detect frequency is greater than 15% and less than or equal to 50% and the data are normally or log-normally distributed (**Section 2.3**), the Kaplan-Meier method will be used to estimate the mean and standard deviation adjusted for the presence of left-censored values.
- If the non-detect frequency is greater than 50% or data are not normally or log-normally distributed (**Section 2.3**), a non-parametric test or calculation will be used.

2.3 Testing for Normality

In accordance with 35 I.A.C. § 845.640(g)(1), "the statistical method used to evaluate groundwater monitoring data must be appropriate for the distribution of constituents". The Unified Guidance document recommends the Shapiro-Wilk normality test for sample sizes of 50 or less, and the Shapiro-Francia normality test for sample sizes greater than 50. Log-transformation of datasets to achieve normal distributions is preferred to using non-parametric methods. However, if data normality cannot be achieved through log transformation, a non-parametric method is used.

2.4 Outlier Evaluation and Management

Groundwater analytical data may be screened for the existence of outliers using methods described by the Unified Guidance. Outliers are extreme data points that may represent an anomaly or erroneous data point. To test for outliers, one or more of the following outlier tests will be utilized:

- Dixon's test, for well-constituent pairs with less than 25 samples, assumes normally distributed data.
- Rosner's test, for well-constituent pairs with more than 20 samples, assumes normally distributed data.
- Grubb's test for well-constituent pairs with seven or more samples, assumes normally distributed data.

In addition, time series, box-whisker plots, and probability plots will be used to provide visual tools to identify potential outliers, and evaluation of seasonal, spatial, or temporal variability for both normally and non-normally distributed data.

When necessary, a confirmatory sample will be collected to allow the facility to distinguish between an outlier and a true release from the facility (35 I.A.C. § 845.650(d)). If re-sampling is necessary, this sample will be collected within 60 days following outlier identification. Rigorous data validation and review is preferred to formal outlier testing and exclusion to ensure that all data used in statistical evaluations is representative of field conditions. Quality control/quality assurance data are collected and data verification is completed in accordance with the QAPP. Project staff familiar with the site and historical data will review the data generated each quarter and facilitate additional validation as needed. Data quality control, groundwater geochemistry, and sampling procedures will be evaluated as potential sources of error leading to an outlier result. Exclusion of potential outliers without an identified source of error may be considered only for data that could cause extremely elevated background concentrations.

2.5 Trend Analysis

Statistical analyses confirming the lack of trend are a fundamental step to confirm the assumption that groundwater quality values (*i.e.,* constituent means) are stationary or constant over time. These analyses allow for evaluation of variation in the background and compliance data for each constituent over time. A statistically significant increasing trend in the background data could indicate an existing release from the CCR unit or alternative source, requiring further investigation. In addition, statistically significant trending background data can result in increased standard deviation and, therefore, greater prediction or tolerance limits. Consequently, the increased prediction or tolerance limit will have less statistical power or ability to identify a release from a CCR unit.

A linear regression, coupled with a t-test for slope significance at a 95% confidence level (or 0.05 significance level), may be used on datasets for each constituent with few non-detects and a normally distributed variance of the mean to evaluate time trends. The Theil-Sen trend line, coupled with the Mann-Kendall test for slope significance at a 95% confidence level (or 0.05 significance level), may be used for datasets with frequent non-detects or non-normal variance. Similarly, trend analyses could also be used on compliance data to evaluate a possible release from the CCR unit.

2.6 Spatial Variation

Spatial trends and/or variation between background wells could indicate an existing release from a CCR unit. If the spatial variability is not due to an existing release, intrawell comparisons in compliance wells may be used to account for spatial variability and monitor for a future release. However, the CCR units being monitored have been placed into service prior to the start of groundwater monitoring and it is unknown whether a previous release has occurred. Accordingly, intrawell comparisons in compliance wells cannot be used to determine the occurrence of a future release, and interwell comparisons between compliance wells and background wells will be used.

2.7 Temporal Variation

Time series plots can be used to identify temporal dependence. Potentially significant temporal components of variability can be identified by graphing single constituent data from multiple wells together on a time series plot. With temporal dependence, the time series plot has a pattern of parallel traces, in which the individual wells will tend to rise and fall together across the sequence of sampling dates. Time series plots can be helpful by plotting multiple constituents over time for the same well, or averaging values for each constituent across wells on each sampling event and then plotting the averages over time. In either case, the plots can signify whether the general concentration pattern over time is simultaneously observed for different constituents. If so, it may indicate that a group of constituents is highly correlated in groundwater or that the same artifacts of sampling and/or lab analysis impacted the results of several monitoring parameters.

2.8 Updating Background

Updating the background dataset periodically by adding recent results to an existing background dataset can improve the statistical power and accuracy of the statistical analysis, especially for non-parametric prediction intervals. The Unified Guidance recommends updating statistical limits (background) when at least four to eight new measurements (every 2 to 4 years under a semiannual monitoring program or 1 to 2 years under a quarterly monitoring program) are available for comparison to historical data. Methods discussed in **Section 2.4** and professional judgement will be used to evaluate whether any individual data points appear to drive an anomalously high background level. A t-test for equal means (if normal data distribution) or a Mann-Whitney or Wilcoxon test for equal medians (if non-normal data distribution) will be conducted to verify that the two groups of background sample populations are statistically different prior to updating any background datasets. A 0.05 significance level will be utilized when evaluating the two populations, with the null hypothesis that the two populations have equal means or medians. In addition, time series graphs or other trend evaluation statistics (such as a Mann-Kendall test) will be conducted on the new background dataset to verify the absence of a release or changing groundwater quality. If the tests indicate that there are no statistical differences between the two background populations, the new data will be combined with the existing dataset. If the two populations are found to be different, the data will be reviewed to evaluate the cause of the difference. If the differences appear to be caused by a release (*i.e.,* if the new data are significantly higher, or lower for pH), then the previous background dataset may continue to be used. Furthermore, verified outliers will not be added to an existing background dataset. Spatial variability among background wells will also be assessed when background datasets are updated to determine whether pooling data is appropriate.

3. COMPLIANCE MONITORING PROGRAM

Compliance Monitoring encompasses data collection and statistical evaluation conducted during unit operation (35 I.A.C. § 845.640 and 845.650) and the post-closure care period (35 I.A.C. § 845.780). Compliance Monitoring is designed to evaluate whether concentrations of constituents listed in 35 I.A.C. § 845.600(a)(1) in compliance wells exceed GWPS or background in a statistically significant manner.

3.1 Monitoring Program Outline

3.1.1 Establish Background and GWPS

A site-specific GWPS will be established for constituents listed in 35 I.A.C. § 845.600(a)(1) for each CCR unit. The GWPS will be the concentration specified in 35 I.A.C. § 845.600(a)(1), unless the background concentration is greater. For this exception, background concentrations will be used to define the GWPS. Background concentrations will be calculated using a parametric or non-parametric upper tolerance limit (UTL), depending on the data distribution, consistent with 35 I.A.C. § 845.640(f)(1)(C). The procedure for calculating a UTL is outlined in **Figure 1** and described in **Section 3.2**. If only one background result is detected, that value will be used as the UTL.

3.1.2 Evaluate Background and GWPS Exceedances

Per 35 I.A.C. § 845.610(b)(3), groundwater monitoring data from compliance monitoring wells will be evaluated for statistically significant exceedances over background and the site-specific GWPS. In accordance with recommendation in the Unified Guidance for compliance monitoring, exceedances are evaluated by comparing a confidence interval (CI) to a fixed standard. The null hypothesis of this comparison is that compliance well groundwater concentrations do not exceed the standard unless the statistical test indicates otherwise.

GWPS exceedances will be determined by comparing the lower confidence limit (LCL) of the compliance well concentrations to the GWPS, except for pH where the LCL will be compared to the upper end of the GWPS range, and the upper confidence limit (UCL) compared to the low end of the GWPS range. A GWPS exceedance is determined if the LCL is greater than the GWPS, and, for pH, either the LCL is greater than the upper end of the GWPS range or the UCL is less than the low end of the GWPS range. The method of calculating the CI (outlined in **Figure 2** and described in **Section 3.3**) will be determined by sample size, trends in the data, and data normality. The significance level (alpha) for this calculation will be fixed at 0.01 (99% confidence) as recommended by Unified Guidance. If there are too few data points to calculate an LCL (a minimum of four data points is typically required), the most recent data point will be compared to the GWPS.

In the event that statistical analyses identify an exceedance of the GWPS for one or more parameters, the exceedance parameters and wells of concern may be immediately re-sampled. Compliance Monitoring statistics will be updated using the verification resample. If the Compliance Monitoring statistics using the compliance verification resample data result in an exceedance of the GWPS, the exceedance is confirmed.

Comparison of groundwater monitoring data to background is required by 35 I.A.C. § 845.610(3)(B), but these background "exceedances" do not carry any compliance implications.

Background exceedances will be determined by comparing the LCL of the compliance well concentrations to the background UTL, with the exception of pH where the UCL of the compliance well concentrations will also be compared to the background lower tolerance limit (LTL). A background exceedance is determined if the LCL is greater than the background UTL, or, for pH, either the LCL is greater than the UTL or the UCL is less than the LTL. If there are too few data points to calculate an LCL (a minimum of four data points is required), the most recent data point will be compared to the background UTL (and LTL for pH).

Additionally, an exceedance of either background or GWPS will be identified if the constituent monitored was not detected in all previous samples at a compliance well and the two most recent samples have both detections and exceed the GPWS (or are less than the low end of the GWPS range for pH) or background UTL (or are less than the LTL for pH).

3.2 Upper Tolerance Limit

The method for calculating a UTL depends primarily on the proportion of non-detects and the data distribution (**Figure 1**). A parametric UTL will be used to calculate the GWPS when the background data are normally distributed and have a non-detect frequency of 50% or less. The Unified Guidance recommends 95% confidence level and 95% coverage (95/95 tolerance interval). When the non-detect frequency is 15% or less, half the RL will be substituted for non-detects (simple substitution), and the normal mean and standard deviation will be calculated. The Kaplan-Meier method will be used when the detection frequency is between 15% and 50%. The Kaplan-Meier method assesses the linearity of a censored probability plot to determine whether the background sample can be approximately normalized. If so, then the Kaplan-Meier method will be used to compute estimates of the mean and standard deviation adjusted for the presence of left-censored values. The Kaplan-Meier estimate of the mean and standard deviation will be substituted for the sample mean and standard deviation.

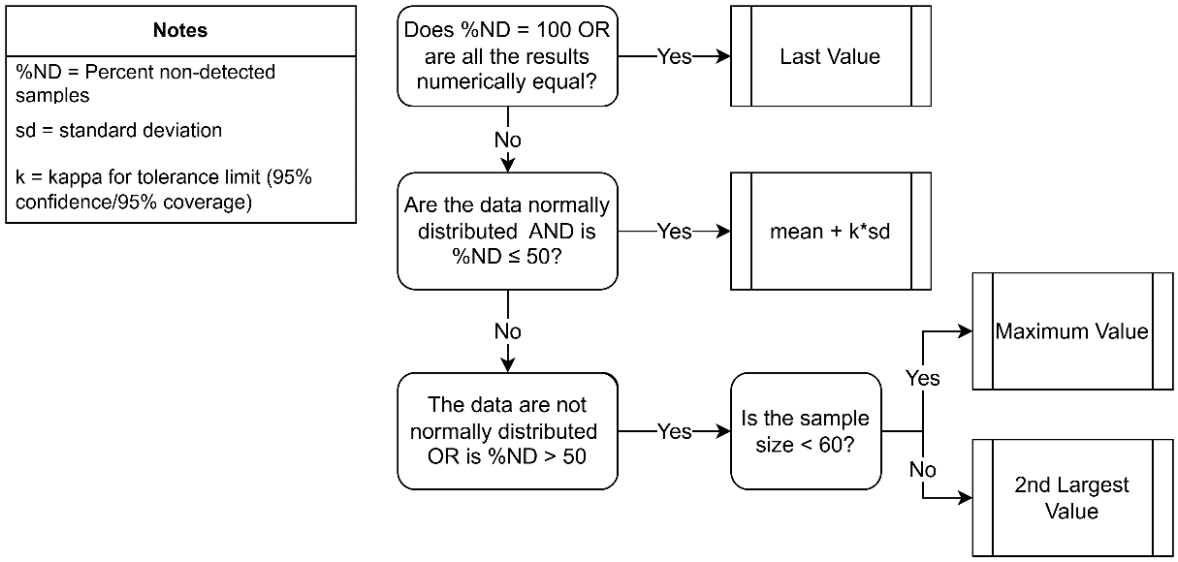

Figure 1. Flow chart illustrating the statistical methods used for calculating background under Compliance Monitoring.

The parametric UTL on a future mean will be calculated from the background dataset as follows:

$$UTL = \overline{x} + \kappa\,(n, \gamma, \alpha - 1) \cdot s$$

$\overline{x}$ = background sample mean

s = background sample standard deviation

$\kappa\,(n, \gamma, \alpha - 1)$ = one-sided normal tolerance factor based on the chosen coverage (γ) and confidence level (α -1) and the size of the background dataset (n). Values may be calculated per Millard (2013) or looked up in Table 17-3 in Appendix D of the Unified Guidance.

If the UTL is constructed on the logarithms of original observations to achieve normality, where $\overline{y}$ and s_y are the log-mean and log-standard deviation, the limit will be exponentiated for back-transformation to the concentration scale as follows:

$$TL = \exp\left[\overline{y} + \kappa\,(n, \gamma, \alpha - 1) \cdot s_y\right]$$

$\overline{y}$ = background sample log-mean

s_y = background sample log-standard deviation

If the background data set is non-parametric or has a non-detect frequency greater than 50%, a non-parametric UTL is used. The maximum concentration is used as the non-parametric UTL for sample sizes less than 60 and the second largest concentration is used as the non-parametric UTL for sample sizes greater than or equal to 60. As described in the Unified Guidance, the advantages include the resulting UTL reflecting actual concentration magnitudes, and the UTL more likely representing a detected concentration (unless all the data were non-detect).

3.3 Confidence Intervals

The method for calculating a CI depends on whether or not there is a trend in the data, the proportion of non-detects, and the data distribution (**Figure 2**). The following sections describe the procedure for calculating the CI in each case.

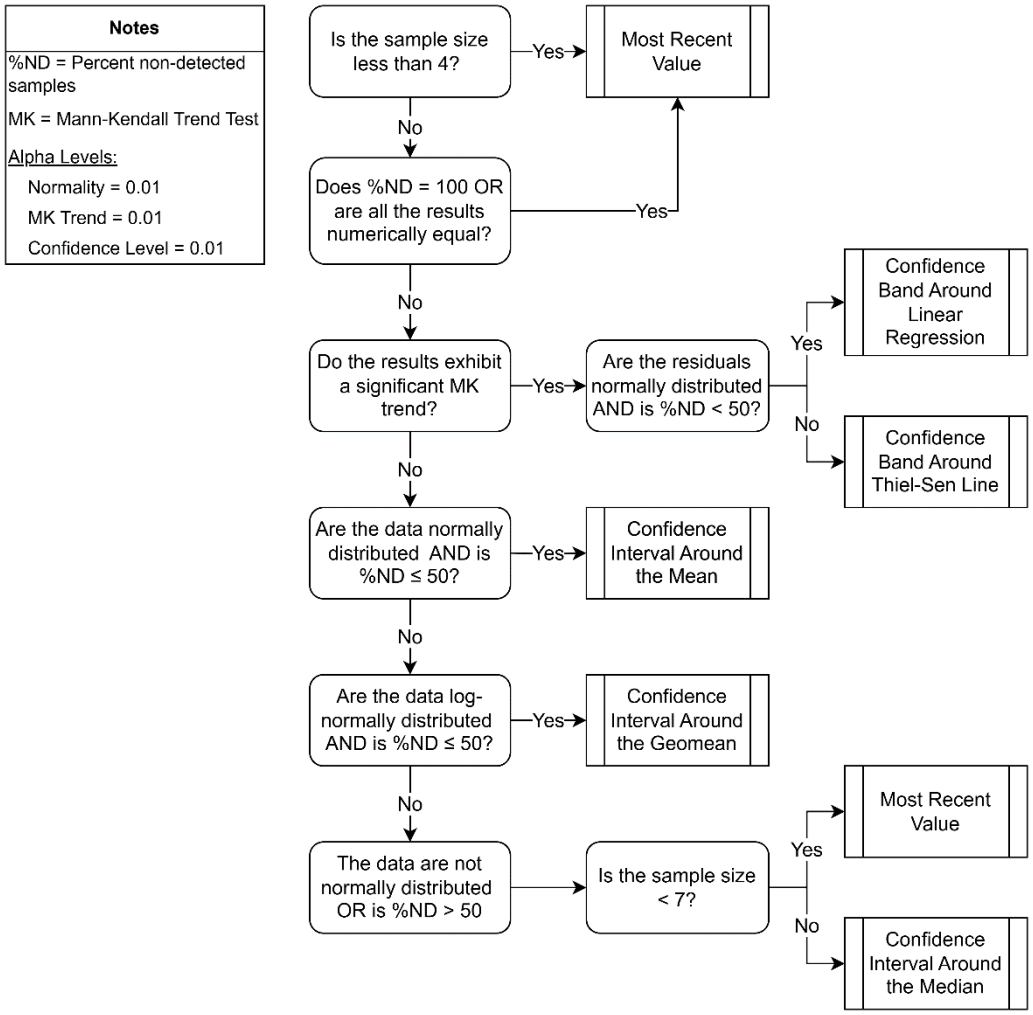

Figure 2. Flow chart illustrating the statistical methods used for calculating confidence intervals in Compliance Monitoring.

3.3.1 Confidence Intervals Around Trending Data

If compliance data exhibit a statistically significant trend based on results from a Mann-Kendall trend test and consists of a sufficient sample size (see below), CIs accounting for trends will be constructed to account for the trend-induced variation. If this is not accounted for, a wider CI will inevitably be calculated for a given confidence level and sample size (n). A wider CI will result in less statistical power, or ability to demonstrate an exceedance or return to compliance. When a linear trend line has been estimated, a series of CIs is estimated at each point along the trend. This creates a simultaneous confidence band that follows the trend line. As the underlying population mean increases or decreases, the confidence band also increases to reflect this change at that point in time.

Linear regression will be used when the compliance data set consists of at least eight samples, the frequency of non-detects is below 50%, and residuals around the trend line are normally distributed. The linear regression of concentration against sampling date (time) will be computed as follows:

$$\hat{b} = \sum_{i=1}^{n} (t_i - \overline{t}) \cdot x_i / (n-1) \cdot s_t^2$$

x_i = i^{th} concentration value and

t_i = i^{th} sampling date

$\overline{t}$ = sampling mean date

s_t^2 = variance of the sampling dates

This estimate leads to the following regression equation:

$$\hat{x} = \overline{x} + \hat{b} \cdot (t - \overline{t})$$

$\overline{x}$ = mean concentration level

$\hat{x}$ = estimated mean concentration at time t

The regression residuals will also be computed at each sampling event to ensure uniformity and lack of significant skewness. Regression residuals will be computed at each sampling event as follows:

$$r_i = x_i - \hat{x}_i$$

The estimated variance around the regression line, or mean squared error, will be computed as follows:

$$s_e^2 = \frac{1}{n-2} \sum_{i=1}^{n} r_i^2$$

The CI around a linear regression trend line given confidence level (1-α) and a point in time (t_0), will be computed as follows:

$$LCL_{1-\alpha} = \hat{x}_0 - \sqrt{2s_e^2 \cdot F_{1-2\alpha,2,n-1} \cdot \left[\frac{1}{n} + \frac{(t_0 - \overline{t})^2}{(n-1) \cdot s_t^2}\right]}$$

$$UCL_{1-\alpha} = \hat{x}_0 - \sqrt{2s_e^2 \cdot F_{1-2\alpha,2,n-2} \cdot \left[\frac{1}{n} + \frac{(t_0 - \overline{t})^2}{(n-1) \cdot s_t^2}\right]}$$

$\hat{x}_0$ = estimated mean concentration from the regression equation at time t_0

$F_{1-2\alpha,2,n-2}$ = upper (1-2α)th percentage point from an *F*-distribution with 2 and (*n*-2) degrees of freedom

If the compliance data set consists of at least seven samples but has a non-detect frequency greater than 50% or the residuals are not normally distributed, the Thiel-Sen trend line will be used as a non-parametric alternative to linear regression for calculation of the CI. The Thiel-Sen trend line estimates the median concentration over time by combining the median pairwise slope with the median concentration value and the median sample date. To compute the Thiel-Sen line,

the data will first be ordered by sampling event x_1, x_2, x_n. All possible distinct pairs of measurements (x_i, x_j) for $j > i$ will be considered and the simple pairwise slope estimate will be computed for each pair as follows:

$$m_{ij} = (x_j - x_i)/(j - i)$$

With a sample size of n, there will be a total of $N = n(n\text{-}1)/2$ pairwise estimates m_{ij}. If a given observation is a non-detect, half the RL will be substituted. The N pairwise slope estimates (m_{ij}) will be ordered from least to greatest (renamed $m_{(1)}$, $m_{(2)}$,..$m_{(N)}$). The Thiel-Sen estimate of slope (Q) will be calculated as the median value of the list depending on whether N is even or odd as follows:

$$Q = \begin{cases} m_{([N+1]/2)} \; if \; N \; is \; odd \\ (m_{(N/2)} + m_{([N+2]/2)})/2 \; if \; N \; is \; even \end{cases}$$

The sample concentration magnitude will be ordered from least to greatest, $x_{(1)}$, $x_{(2)}$, to $x_{(n)}$ and the median concentration will be calculated as follows:

$$\tilde{x} = \begin{cases} x_{([n+1]/2)} \; if \; n \; is \; odd \\ (x_{(n/2)} + x_{([n+2]/2)})/2 \; if \; n \; is \; even \end{cases}$$

The median sampling date ($\tilde{t}$) with ordered times ($t_{(1)}$, $t_{(2)}$, to $t_{(n)}$) will also be determined in this way. The Thiel-Sen trend line will then be computed for an estimate at any time (t) of the expected median concentration (x) as follows:

$$x = \tilde{x} + Q \cdot (\mathrm{t} - \tilde{t}) = (\tilde{x} - Q \cdot \tilde{t}) + Q \cdot \mathrm{t}$$

To construct a confidence band around the Thiel-Sen line, sample pairs (t_i, x_i) will be formed with a sample date (t_i) and the concentration measurement from that date (x_i). Bootstrap samples (B) will be formed by repeatedly sampling n pairs at random with replacement from the original sample pairs. This will be repeated 500 times. For each bootstrap sample, a Thiel-Sen trend line will be constructed using the equation above. A series of equally spaced t_j values will be identified along the range of sampling dates represented in the original sample, j=1 to m. The Thiel-Sen trend line associated with each bootstrap replicate will be used to compute an estimated concentration ($\hat{x}_j^B$). A CI will be constructed for the lower αth percentile $\hat{x}_j^{[\alpha]}$from the distribution of estimated concentrations at each time point (t_j). For a UCL, compute the upper (1-α)th percentile, $\hat{x}_j^{[1-\alpha]}$ at each t_j; for an LCL, compute the lower αth percentile, $\hat{x}_j^{[\alpha]}$ at each t_j.

3.3.2 Parametric Confidence Intervals around a Mean

If compliance data do not show a trend and are normal or log-normal, one-sided parametric CIs around a sample mean will be constructed for each constituent and well pair. The LCL will be calculated as:

$$LCL_{1-\alpha} = \overline{x} - t_{1-\alpha,n-1} \cdot \frac{s}{\sqrt{n}}$$

The UCL will be calculated as:

$$UCL_{1-\alpha} = \overline{x} + t_{1-\alpha,n-1} \cdot \frac{s}{\sqrt{n}}$$

$\overline{x}$ = compliance sample mean

s = compliance sample standard deviation

n = compliance sample size

$t_{1-\alpha,n-1}$ = obtained from a Student's t-table with (n–1) degrees of freedom at the chosen alpha level (0.01) (Table 16-1 in Appendix D of the Unified Guidance)

If compliance data are distributed lognormally, the LCL will be computed around the lognormal geometric mean as:

$$LCL_{1-\alpha} = \exp\left(\overline{y} - t_{1-\alpha,n-1} \cdot \frac{s_y}{\sqrt{n}}\right)$$

The UCL will be computed around the lognormal geometric mean as:

$$UCL_{1-\alpha} = \exp\left(\overline{y} + t_{1-\alpha,n-1} \cdot \frac{s_y}{\sqrt{n}}\right)$$

$\overline{y}$ = compliance sample log-mean

s_y = compliance sample log-standard deviation

3.3.3 Non-Parametric Confidence Intervals around a Median

Non-parametric confidence intervals around the median will be computed if the compliance data do not show a trend and contain greater than 50% non-detects or are non-normally distributed. The mathematical algorithm used to construct non-parametric CIs is based on the probability p that any randomly-selected measurement in a sample of n concentration measurements will be less than an unknown p x 100th percentile of interest (where P is between 0 and 1). Then the probability that the measurement will exceed the p x 100th percentile is (1–p). The number of sample values falling below the p x 100th percentile out of a set of n should follow a binomial distribution with parameters n and success probability p, where 'success' is defined as the event that a sample measurement is below the p x 100th percentile. The probability that the interval formed by a given pair of order statistics will contain the percentile of interest will then be determined by a cumulative binomial distribution *Bin(x;n,p)*, representing the probability of x or fewer successes occurring in n trials with success probability p. P will be set to 0.50 for an interval around the median. In accordance with the Unified Guidance, a confidence interval around the median will only be calculated if at least seven data points are available.

The sample size n will be ordered from least to greatest. Given p = 0.50, candidate interval endpoints will be chosen by ordered data values with ranks rounded upward to the next higher integers. The ranks of the endpoint will be denoted L^* and U* and are calculated using the following equations (Conover, 1999, p. 144):

$$L^* = np - Z_{1-\alpha}\sqrt{np(1-p)}$$

$$U^* = np + Z_{1-\alpha}\sqrt{np(1-p)}$$

4. CORRECTIVE ACTION MONITORING PROGRAM

Corrective Action Monitoring is performed after a corrective action remedy has been selected and implemented. 35 I.A.C. § 845.680(a)(1) specifies that the corrective action groundwater monitoring program must meet the requirements listed in 35 I.A.C. § 845.650 (*i.e.*, Compliance Monitoring), document the effectiveness of the selected remedy, and demonstrate compliance with the GWPS. Post-Closure Care monitoring as described in **Section 3** will operate concurrently with Corrective Action Monitoring, fulfilling the requirements of 35 I.A.C. § 845.650. This document describes the statistical methods used to document the progress of the selected remedy and demonstrate compliance with the GWPS.

Evaluation of corrective action remedy effectiveness will occur in three phases: remedy progress evaluation, stability evaluation, and attainment evaluation (USEPA, 1992).

1. Remedy progress evaluation occurs after implementation of corrective actions to assess if the remedy is functioning as anticipated.
2. The stability evaluation, which occurs after treatment has been concluded and a re-equilibration period has elapsed, assesses if a new post-treatment steady state in the groundwater has been reached.
3. Attainment evaluation occurs after a new steady state has been achieved and assesses if COC concentrations are below the GWPS.

In accordance with the Unified Guidance, these evaluations only apply to constituents which have previous exceedances of the GWPS. Constituents without previous GWPS exceedances continue to be evaluated according to Compliance Monitoring (per **Section 3**). The Corrective Action GMP for each unit describes the detailed approach to remedy effectiveness evaluation and reporting. Statistical evaluations used in each of these three phases are described below.

4.1 Remedy Progress Evaluation

The goal of remedy progress evaluation is to determine if a groundwater remedy is on track to achieve cleanup standards within the proposed time frame and to inform adaptive management decisions if performance metrics are not achieved. Evaluations of remedy effectiveness include:

- Comparison of the central tendency (*i.e.*, mean or median) of data from corrective action monitoring wells to the GWPS
- Trend analysis of average concentrations in individual wells and in a plume

Unlike Compliance Monitoring, remedy progress evaluation does not result in the determination of exceedances. Instead, the results from these analyses are used to evaluate performance metrics described in the site-specific Corrective Action GMP.

4.1.1 Central Tendency

The two most common central tendency measures of a data set are the sample mean and sample median. The sample mean best represents the central tendency of normally-distributed data; therefore, the mean will be used to represent the tendency if the data are approximately normally distributed and the frequency of non-detects is below 50%. The sample mean is given by the arithmetic average of each value in the sample:

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$$

$\bar{x}$ = sample mean

n = sample count

x_i = i^{th} observation of x

The sample median is the 50th percentile of values in a sample and represents the midpoint of the ordered list of values. Because it is based on rank-order, the sample median is insensitive to data distribution; therefore, the median will be used if the data are not normally distributed or the frequency of non-detects is 50% or greater. The sample median is determined by arranging all values in order and selecting the middle value (or, if an even number of values exists, the mean of the two middle values).

4.1.2 Trend of Average Concentration in Individual Wells and in a Plume

Insight into remedy progress can be gained by evaluating changes in concentration at both the individual well and plume levels.

Trends at the individual well level are evaluated according to **Section 2.5**. To evaluate trends at the plume level, the trend on quarterly average concentrations is evaluated (per **Section 4.1.1**). Quarterly average concentrations in the plume are generated by calculating the mean or median as appropriate based on distribution (**Section 4.1.1**) of concentrations collected during a single sample event. Trend is then evaluated as described in **Section 2.5**. The magnitude of the trend (*i.e.*, slope) may be evaluated according to methods in **Section 3.3.1**.

4.2 Stability Evaluation

In order to evaluate ultimate effectiveness of the remedy, it is critical to evaluate if a new stable equilibrium has been reached after the implementation of corrective action (e.g., completion of source control or conclusion of groundwater extraction). Stability evaluation will be completed using trend analysis as described in **Section 2.5**.

4.3 Attainment Evaluation

Per 35 I.A.C. § 845.680(c), corrective action is considered complete when compliance with the GWPS has been demonstrated "at all points within the plume of contamination that lies beyond the waste boundary […] for a period of three consecutive years". Accordingly, attainment of the GWPS will be evaluated for well-constituent pairs previously determined to exceed the GWPS. This evaluation will include data collected after groundwater conditions have stabilized (**Section 4.2**).

The Unified Guidance recommends comparing a CI to the fixed GWPS to evaluate attainment of corrective action. The null hypothesis of this test is the reverse of that in Compliance Monitoring: corrective action well groundwater concentrations are assumed to exceed the GWPS unless the statistical test indicates otherwise. The CI will be calculated according to methods presented in **Section 3.3**. For pH, the only parameter with an upper and lower background and GWPS, the GWPS will be attained (*i.e.*, the null hypothesis rejected) when the CI falls within the range of the GWPS (*i.e.*, if the LCL of the CI is above the lower limit and the UCL is below the upper limit). For all other parameters, the GWPS will be attained when the UCL is below the GWPS. Once this

statistical evaluation indicates that GWPS has been met for three years (*i.e.*, that the null hypothesis is rejected), corrective action will be concluded.

1 INTRODUCTION

1.1 OVERVIEW

This Hydrogeologic Site Characterization Report was prepared by Natural Resource Technology, Inc., an OBG Company (NRT) in support of a Closure Plan for impoundments located at the Hennepin Power Station, Hennepin, Illinois which is owned by Dynegy Midwest Generation, LLC (DMG). This report and the Closure Plan apply to Coal Combustion Residuals (CCR) surface impoundments associated with the Hennepin West Ash Pond System and not to any of the other impoundments present on the Site (i.e. East Ash Pond System). However, information gathered to evaluate other CCR units on site regarding geology, hydrogeology, and groundwater quality is included, where appropriate. The Hennepin West Ash Pond System includes the following components:

Old West Ash Pond (which includes Pond No.1: 9.3 acres and Pond No. 3: 16.4 acres)

- Old West Polishing Pond: 4.7 acres [Polishing Pond]

Numerous hydrogeologic investigations have been performed concerning the CCR Units located at the Site. The information presented in this site characterization report includes recent data collected to comply with the Federal CCR Rule (40 CFR Part 257) as well as comprehensive data collection and evaluations from prior hydrogeologic investigation reports, including, but not limited to, the following:

- ***Hydrogeologic Study, Existing Ash Ponds, Hennepin Power Plant, Illinois Power Company, Hennepin, Illinois. John Mathes & Associates, Inc.; April 19, 1983.*** Five monitoring wells were installed, currently designated as wells 21 through 25. Monitoring wells 21 through 24 are downgradient of the West Ash Pond System and well 25 is an upgradient well located south of the impoundment. Grain size analyses were performed on soil samples.
- ***Investigation of Site Closure Options at Illinois Power Company's West Ash Impoundment. Report No. STMI/135/97-01. Science & Technology Management, Inc.; September, 1997.*** A supplemental hydrogeologic characterization was conducted to further characterize the West Ash Pond System, develop a groundwater flow and transport model and evaluate three alternative closure options using the model. Seven new permanent monitoring wells (26, 27, 30, 31, 32, 33, 34) and three new temporary leachate wells (L1, L3, L4) were installed around and within the impoundment. Field permeability tests were conducted on seven wells.
- ***Model Recalibration and Prediction of Closure Options for the West Ash Impoundment; Hennepin Power Station Putnam County, Illinois. Natural Resource Technology, Inc.; October, 2002.*** NRT drilled four soil borings within the ash impoundment (A1, A3, 23S, L5), installed monitoring well 35 along the south berm of Pond No. 3, well 36 south of Pond No. 1, and installed one leachate well L5 within the east end of Pond No. 3 in support of a groundwater flow and transport model for predicting future boron concentrations. The principal objective of the additional boring and well installation was to better define the depth of the ash ponds and determine the thickness of saturated ash. Additional groundwater quality data within the impoundment and along the south side the Old West Ash Pond was collected from the new wells for recalibrating the 1997 STMI groundwater model.
- ***Water Well Survey, Dynegy Midwest Generation, Hennepin Power Station, Hennepin, Illinois. Natural Resource Technology and Kelron Environmental; June 3, 2009.*** A water well survey was performed in accordance with the "Right to Know" Potable Water Well Survey procedures of 35 Illinois Administrative Code 1600.210(b)(1) and 1600.210(b)(2). The purpose of this survey was to identify water wells located within 2,500 feet of DMG's Hennepin Power Station property boundary.
- ***Assessment of Potential for Groundwater Impact on Identified Water Wells, Dynegy Midwest Generation, Hennepin Power Station, Hennepin, Illinois. Natural Resource Technology and Kelron Environmental; August 26, 2009.*** An assessment of the potential for impact of the ash impoundment on water quality of potable water wells identified in the water well survey.

- ***Hydrogeologic Summary and Groundwater Quality Assessment, West Ash Pond System, Hennepin Power Station, Hennepin, Illinois. Natural Resource Technology, Inc., July 24, 2014.*** The summary, including four quarters of groundwater quality monitoring, was conducted to develop information necessary to recalibrate the existing groundwater model of the West Ash Pond System and evaluate closure alternatives for the impoundment. This report is a compendium and reanalysis of information from three previous reports prepared for the West Ash Pond System along with an assessment of the most recent groundwater data collected from a network of 16 wells (14 monitoring wells and 2 leachate wells) in 2013 and 2014.
- ***Closure Alternatives Evaluation, West Ash Pond System, Hennepin Power Station, Hennepin, Illinois. Natural Resource Technology, Inc., July 24, 2014.*** This evaluation documented alternatives for closure of the West Ash Pond System, based on their effectiveness, implementation feasibility, and construction and maintenance costs. Groundwater transport modeling was completed to assess the effects of alternatives on surrounding groundwater quality. Implementation feasibility and costs were presented along with a recommended alternative.
- ***Monitoring Well 49 Installation. Natural Resource Technology, Inc., July 6, 2015.*** Documents the installation of CCR monitoring network Well 49.
- ***30% Design Data Report for Dynegy Hennepin Power Station; West Polishing Pond, West Ash Pond, East Ash Pond and Ash Pond No. 2 CCR Units. AECOM, January 12, 2016.*** The data package included summary tables, geotechnical laboratory data and exploratory logs for 32 auger borings, 38 CPT soundings and 7 standpipe piezometers installed at selected locations around the West Ash Pond System.
- ***Old West Polishing Pond Subsurface Investigation, Hennepin Power Station, Hennepin, Illinois. Civil & Environmental Consultants, Inc. (CEC), April 1, 2016.*** Data package included logs for 9 piston sampling and push probe borings along with two impoundment cross-sections within the Old West Polishing Pond of the West Ash Pond System.
- ***Closure Work Plan Annual Report, Hennepin Power Station, West Ash Pond System: Nos. 1 and 3. Dynegy Operating Company. Natural Resource Technology, Inc., October 21, 2016.*** In accordance with the Closure Work Plan approved by the Illinois EPA (November 8, 1996), DMG is required to perform groundwater monitoring and prepare annual reports for the Old West Ash Pond System. These annual reports have been submitted to the Illinois EPA from October 2000 through October 2016. Although the number of monitoring wells, sampling frequency, and water quality parameters has changed, these annual reports have documented the groundwater levels, flow, and water quality at the West Ash Pond System for all of the monitoring events conducted over a 16-year period.
- ***Subsurface Investigation Within West Ash Ponds 1 and 3. CEC, March 2017.*** Data package included boring logs for 20 auger borings, four impoundment cross-sections, well construction logs for 6 ash leachate wells and leachate elevations within the West Ash Pond System.

In conjunction with this report, a Groundwater Monitoring Plan and a Groundwater Management Zone Application are being prepared to support the closure of the West Ash Pond Complex. In addition, the groundwater flow and transport models were updated to evaluate the effect of various ash pond closure scenarios on groundwater quality and to predict the fate and transport of CCR leachate components (NRT, 2017c). Modeling has also been conducted to enable estimation of the time required for hydrostatic equilibrium of groundwater to be achieved beneath the West Ash Pond Complex (NRT, 2017d).

1.2 SITE LOCATION AND BACKGROUND

The West Ash Pond System is located in the northeast quarter of Section 27, Township 33 North, Range 2 West, Putnam County, Illinois and approximately 3 miles north-northeast of the Village of Hennepin (Figure 1). The impoundments are situated less than 200 feet south of the Illinois River and approximately one mile east of the Big Bend, where the river shifts course from predominantly west to predominantly south. The impoundment is bordered to the southeast by farm fields (i.e. corn and soybeans) with scattered clumps of rows or trees; to the southwest and west by low lying floodplains within the Donnelley Wildlife Management Area (Donnelley WMA)

administered by the Illinois Department of Natural Resources (IDNR); and to the east by the power generating facility (Figure 2).

Ponds are maintained within the Donnelley WMA for migratory waterfowl. Water levels in these ponds are maintained by a system of pumps operated during migration season, with water pumped from the Illinois River through a channel that runs immediately west of the Old West Polishing Pond. The Donnelley WMA is predominantly a swampy area vegetated by grasses and trees.

The eastern third of the impoundment is on a terrace about 15 feet higher than normal river stage. The western two-thirds are on lowlands that are about 5 to 10 feet higher than normal river stage.

1.3 SITE HISTORY

The Hennepin Power Station had two coal-fired units constructed in 1953 and 1959 with a capacity of 210 MW. The coal source changed several times since the station was constructed; however, all coal ash disposed to the West Ash Pond System is derived from Illinois coal.

DMG operated the West Ash Pond System at the Hennepin Power Station from 1952 through 1996. The impoundment consists of two units, all of which are now out-of-service. The Old West Ash Pond which includes Pond No. 1, at the eastern end of the impoundment, which primarily consists of bottom ash and slag and Pond No. 3, in the central portion of the impoundment, which contains mixed coal ash. The Old West Polishing Pond is located at the western end of the impoundment. All of the ponds are bermed. The berms, which are 15 feet above grade, were constructed from locally occurring sandy soils. The entire west impoundment covers an area of approximately 30.4 acres.

During operation, service water was used to sluice fly ash, bottom ash, and low-volume wastes to the impoundment. There was initially a surface water discharge from this impoundment which ceased after the impoundment was reworked in 1989. At the time the impoundment was removed from service in late 1996, there was no surface water discharge and all sluice water ex-filtrated via evapotranspiration, seepage through the berms, or leakage through the base of the ponds.

Coal ash sluiced to this impoundment was a by-product of high-sulfur Illinois coal. The operational history of the West Ash Pond System is as follows:

- 1952 – 1955: Construction of Old West Ash Pond, Pond No. 1. Berms constructed from locally sandy materials to an original elevation (since modified) of 457 feet.
- 1968: Construction of Old West Ash Pond, Pond No. 3. Berms were constructed to an elevation of 457 feet.
- 1979: Berms surrounding the Old West Ash Pond raised by 3 feet to elevation of 460 feet.
- 1988 – 1989: Ponds No. 1 and No. 3 within the Old West Ash Pond were consolidated and divided into primary and secondary cells, and the berm around the primary portion was raised 5 feet to an elevation of 465 feet. It was after this consolidation that surface water discharge from the impoundment ceased.
- December 1996: West Ash Pond System Ponds No. 1 and No. 3 were removed from service.

The West Ash Pond System was not capped following removal from service in order to facilitate future mining and beneficial re-use of the ash. The impoundment is partially dewatered by gravity drainage, although pumps were used to complete the dewatering process in 1998. The ash is currently dry over most of the surface through most of the year except for (i) the Old West Polishing Pond, which always contains water; and, (ii) the western end of the Old West Ash Pond, Pond No. 3, where runoff water collects and is ponded most of the year.

The ash at the surface of the Old West Ash Pond supports some vegetation. The surface topography of ash in, Pond No. 1 is uneven with no pronounced slope. The top of ash in Pond No. 3 slopes downward from the east, where the sluiced ash inlet was located, to the west. Top of ash elevation in all three ponds is lower than the surrounding berms, providing full containment. There are no controls to collect storm water so all runoff collects in the lowest portion of each pond, where it evaporates or infiltrates through the ash.

2 REGIONAL AND LOCAL GEOLOGY

2.1 TOPOGRAPHY

There are three geomorphic features dominant in the immediate vicinity of the Hennepin Power Station: an upper river terrace at an elevation of about 500 to 550 feet, a lower river terrace at an elevation of about 450 to 460 feet, and the current river valley filled with alluvium to an elevation of about 445 feet. The power station and eastern portion of the west impoundment (Old West Ash Pond, Pond No. 1) are on the narrow lower terrace between the Illinois River and the uplands. The western portion of the impoundment (most of Old West Ash Pond, Pond No. 3 and Old West Polishing Pond) overlies alluvium.

2.2 REGIONAL GEOMORPHOLOGY

The Hennepin Power Station is in the Bloomington Ridged Plain Section of the Central Lowland Province. The Bloomington Ridged Plain includes most of the Wisconsinan Stage moraines and is characterized by low, broad morainic ridges with intervening stretches of relatively flat or gently rolling ground moraine. Drainage is generally in the initial stages of development, and most streams follow, and are eroding, in constructional depressions, many of which cross morainic ridges. The valleys of principal streams are large and have floodplains bordered by valley-train terraces. The Illinois River has a broad, flat-bottomed valley with steep walls and is bordered by numerous steep-walled valleys with steep gradients.

2.3 SOILS

Surficial soils at the West Ash Pond System and vicinity are shown on Figure 3, based on the soil survey performed in Putnam County in 1986 (Soil Conservation Service, May 1992). Former soils underlying the impoundment are identified as Moundprairie Silty Clay Loam, wet. The Moundprairie series soils consist of poorly drained, moderately permeable soils on floodplains. These soils formed in alluvium. This soil association is well suited for and used as habitat for wetland wildlife. These soils are unsuitable for dwellings and only moderately suitable for cultivated crops, due to shallow water table and flooding.

The area west of the Old West Polishing Pond is designated Moundprairie Silty Clay Loam, frequently flooded. Areas south of the Old West Polishing Pond and Pond No. 3 are also designated as wet or frequently flooded Moundprairie Silty Clay Loam. South of the eastern end of the impoundment (i.e. south of Pond No. 1) are several units, including: Rodman Gravelly Sandy Loam, 12 – 30% slopes; Landes Fine Sandy Loam, occasionally flooded; Ade Loamy Fine Sand, 1 – 7% slopes; and, Dakota Loam, 0 – 2 % slopes. The power station and coal pile area located east of the impoundment are classified as urban land.

2.4 BEDROCK

2.4.1 Lithology

The uppermost bedrock near the Hennepin Power Station, including the West Ash Pond System, is the Pennsylvanian Carbondale Formation (Kolata, 2005), which consists of shale with thin limestone, sandstone, and coal beds (Figure 4). The bedrock surface elevation in the vicinity of the Site is between 400 and 450 feet (Willman et al., 1967). Three deeper borings around the perimeter of the East Ash Pond System confirm the presence of shale bedrock between elevations 400 and 410. Water well logs at the power plant indicate shale bedrock at an elevation of roughly 350.

The thickness of the Pennsylvanian rocks range from 150 feet in the western part of Putnam County to more than 525 feet along the eastern margin of the county (Woller, 1976). In the vicinity of the Site, the Pennsylvanian rocks have an estimated thickness of approximately 300 to 400 feet. Beneath the Pennsylvanian rocks are Mississippian and Devonian-age interbedded layers of limestone and shale over Silurian-age dolomite. The dolomite generally ranges in thickness from 410 to 505 feet in the immediate region (Willman, 1942; Frankie, 2002). Crevassing in the unit varies widely and well yields are inconsistent.

Deeper bedrock units beneath the Silurian-age dolomite consist of the following in descending order (Woller, 1976; Frankie, 2002):

- Maquoketa Shale Group of Ordovician age, composed primarily of blue to green shales with some limestone and dolomite layers, occurs at depths of less than 1,000 feet in the northwest part of Putnam County to 1,200 feet in southern Putnam County, with a thickness generally ranging from 155 to 240 feet. This shale is an aquitard between the Silurian dolomite and deeper dolomite and sandstone aquifers.
- Ordovician age dolomite and sandstone aquifers, including the following:
  - Galena-Platteville Dolomite Group at depths of about 1,150 feet in northwest Putnam County to about 1,400 feet in the southeast, ranging in thickness from 320 to 380 feet
  - Glenwood-St. Peter Sandstone at depths of about 1,450 feet in west Putnam County near the site to 1,750 feet in the southeast part of the county, ranging in thickness from about 120 to 170 feet
  - Dolomite with some shale and sandstone beds below depths of 1,750 to 1,800 feet near the site, principally consisting of the Shakopee (130 to 150 feet thick), New Richmond (approximately 165 feet thick), and the Oneota (approximately 215 feet thick) formations
  - Cambrian age dolomite and sandstone aquifers, including the Ironton-Galesville and Elmhurst-Mt. Simon formations
  - Precambrian age igneous and metamorphic

Based on the directory of coal mines for Putnam County (ISGS, 2006), the nearest coal mines in the vicinity of the site are located approximately 3 miles to the northeast and 4 miles to the southeast. These mines, identified as #8 and #298, are both abandoned underground shaft mines that used the longwall method of mining, essentially removing all of the coal. The #8 mine, called the Lacey Mine, was active from 1883 to 1890. The coal seam at this location ranged from 28 to 42 inches in thickness. The #298 mine, called the St. Paul Mine, and later the Prairie State Mine, operated from 1905 to 1925 and from 1930 to 1939. The coal seam at this location ranged from 42 to 66 inches in thickness.

The coal mined is called the Colchester Seam, also known as the No. 2 and LaSalle Seam. The Colchester Seam is located within the lower portion of the Carbondale Formation, which is the shallowest coal mined in the region. In the vicinity of the site, the Colchester Coal occurs at a depth of approximately 200 to 300 feet.

2.4.2 Structure

The major geologic structural features around Illinois are shown on Figure 5. The Hennepin Power Station is located within a relatively stable region of the continent within the north-central portion of the Illinois Basin. Rock units to the northeast of the Site form the La Salle Anticlinorium where folds are expressed in synclines, anticlines, arches, and monoclines present in the area (Nelson 1995; Anderson 1988). The Paleozoic bedrock strata, consisting of Pennsylvanian and older rocks, have a southwestern regional dip of approximately 15 to 30 feet per mile due to the effects of the anticlinorium. Variations to the bedrock dip occur in areas where there are local structures. The anticlinorium has subparallel anticlines, domes, monoclines, and synclines, which can change local dip and strike of bedrock units (Nelson, 1995).

2.4.3 Seismic Setting

The Sandwich Fault Zone is located approximately 35 miles northeast of the Site (Figure 5). Vertical displacement on the Sandwich Fault Zone ranges from 150 to 800 feet. The fault zone is downthrown to the northeast. Due to the depth of burial by Quaternary sediments and the lack of well or seismic data, detailed information about the fault zone is unavailable. Although depicted as a single fault on this map, evidence from surrounding counties indicates that the Sandwich Fault Zone is a complex configuration of many faults of varying direction and amount of displacement (Kolata, 1976).

The Plum River Fault Zone is a 112 mile long, east-west trending zone of high-angle faulting in east-central Iowa and northwest Illinois, roughly 60 miles northwest of the Site. The north side of the fault zone is downthrown,

with documented net vertical displacements of Silurian strata up to 270 feet. The physical relationships of Pennsylvanian deposits to the Plum River Fault Zone are not known with sufficient precision to preclude up to 33 feet of post-Pennsylvanian displacement. Historic data are inadequate to evaluate the potential for seismic hazard associated with the Plum River Fault Zone (Bunker, B.J., G.A. Ludvigson, B.J. Witzke, 1985). United States Geological Survey (USGS) seismic hazard maps show no enhanced ground acceleration in the Plum River Fault Zone vicinity.

2.5 UNLITHIFIED DEPOSITS GEOLOGY

2.5.1 General Unlithified Geology

The unlithified geologic deposits covering bedrock in the region surrounding the West Ash Pond System are derived from recent river deposition (alluvium), glacial outwash, and glacial till deposits. Total unlithified (drift) thickness ranges from 50 to 200 feet, generally becoming thicker with distance from the Illinois River southward from the impoundment. The geologic history of the Illinois River Valley was described in detail by Willman (1973), Hansel (1996), and Frankie (2002).

The Illinoian and Wisconsinan glaciers repeatedly moved over the area. The Illinois River established its present position during the Woodfordian substage of Wisconsinan glaciation, which covered the area as far south as Peoria. Wisconsinan drift lies directly on bedrock as a result of repeated Woodfordian glacial episodes eroding earlier deposits of loess and glacial drift.

During the glacial retreats from the Hennepin area, numerous moraines were deposited across the Illinois Valley. Large areas between these moraines and/or the glaciers subsequently flooded from meltwaters. One such lake was glacial Lake Illinois, which formed behind the Bloomington Moraine, crossing the Illinois River valley near Peoria. Rapid melting and drainage from this area (Kankakee Flood) deepened and widened the valley, cutting an extensive terrace at an elevation of 500 to 550 feet about 14,500 years ago. These deposits (Henry Formation) are mostly fine gravel and pebbly sand and may be as much as 150 to 200 feet thick in the large terrace on which the city of Hennepin is located (areas shown as 'gh' on Figure 6), along with the eastern (i.e. East Ash Pond System) and southeastern portion of the Hennepin Power Station property.

Another major flooded area formed behind the Tinley Moraine creating Lake Chicago. During downcutting of the Lake Chicago outlet about 3,000 years ago, the Chicago Outlet River deposited coarse gravel in bars on the eroded surfaces. The lower river terrace that underlies the eastern end of the west impoundment (Pond No. 1) includes deposits of the Chicago Outlet River. These deposits commonly occur about 20 to 40 feet above the Illinois River and may be up to about 50 feet in thickness. They are generally coarser and more uniformly sorted than the higher terrace deposits that occur immediately south of the Site.

The Illinois River is currently shallowly entrenched in glacial outwash and the Chicago Outlet River deposits. Lateral erosion by the river has developed a floodplain and deposited alluvium (Cahokia Alluvium) in abandoned channels. Alluvial deposits of the modern Illinois River consist largely of clayey silt and sandy silt with lenses of sand and gravel. The alluvium, where present, is 20 to 40 feet thick, overlying thick deposits of sand and gravel of the Henry Formation. These areas (shown as 'al' on Figure 6), are located beneath the Old West Polishing Pond, most of Pond No. 3, and areas to the west and southwest of the West Ash Pond System.

2.5.2 Detailed Site Lithology

Borings performed at the West Ash Pond System and vicinity are shown on Figure 7. Boring logs are provided in Appendix A. The four principal stratigraphic layers encountered at the West Ash Pond System and adjacent areas are:

1. Fill - coal combustion residuals (CCRs) consisting primarily of fly ash with lesser amounts of bottom ash and slag. This layer also includes the constructed fill berms around the ash ponds, which contain variable admixtures of CCRs and re-worked native silt, clay and sand
2. Alluvial fine grained silts and clays, classified as Cahokia Alluvium

3. Alluvial fine to medium sands
4. Sand and gravel with boulders, deposited by glacial meltwaters and classified as Henry Formation

The river-laid deposits are classified as Cahokia Alluvium. The Henry Formation sands and gravels make up the upper and lower terraces, and fill the valley beneath the alluvium. A fifth stratigraphic layer (Layer 5) – loamy and sandy diamicton (i.e. till) of the Wedron or Glasford Formation – was encountered at one location (Boring 32) approximately 2,560 feet (½ mile) south of the western end of the impoundment.

The stratigraphy of unlithified materials underlying the Henry Formation is uncertain, but it is assumed based on nearby borings at the power plant, East Ash Pond System, and vicinity that the Henry Formation most likely sits directly on top of bedrock in the vicinity of the West Ash Pond System. However, based on the identification of till approximately ½ mile south of the impoundment, it is possible that at some locations either till or an older sand formation, the Sankoty Sand, lies between the Henry Formation sand and gravel and bedrock.

The west impoundment lies over both glacial deposits (Henry Formation) and alluvium (Cahokia Alluvium). Pond No. 1 lies on top of lower terrace glacial deposits. The eastern portion of Pond No. 3 overlies alluvial sand, while the western portion of Pond No. 3 and the Old West Polishing Pond overlay silty clay alluvial channel fill deposits (Figure 8). Borings have been performed within the ash ponds to assess ash thickness and underlying soil types (CEC, 2016, 2017). West-east cross-section lines A-A' and B-B', and north-south cross-section lines C-C' and D-D', are shown on Figures 9 and 10, respectively.

Cross-section line A-A' through the central portion of the West Ash Pond System begins at Boring 34 (west of the impoundment) with silty and organic alluvial clays (Layer 2) that are 26.5 feet thick and underlain by over 11 feet of fine to medium grained alluvial sands (Layer 3). At the west end of the Old West Polishing Pond (Boring 21) are approximately 10 feet of CCRs (Layer 1) underlain by 34 feet of clay and silt (Layer 2) and greater than 8 feet of fine sand (Layer 3). At the west end of Pond No. 3 at Boring L1 there are 25 feet of CCRs underlain by more than 17 feet of silty clay and silt deposits of Layer 2. In the center of Pond No. 3 at Boring L3 there are 14.5 feet of CCRs underlain by 10.5 feet of fine sand (Layer 3) and greater than 25 feet of sand and gravel (Layer 4). The east end of Pond 3 contains 17 to 18 feet of CCRs underlain by 9 feet of silty clay and clayey silt at Boring L5 (Layer 2) and at least 1.5 feet of clayey silt and silty fine sand (Layer 3) at Boring A3, underlain by sand and gravel (Layer 4). The center of Pond No. 1 (Boring L2) has 25 feet of CCRs underlain by 3.5 feet of fine silty sand (Layer 3) and greater than 17.5 feet of gravel with sand (Layer 4).

West-east cross-section line B-B', located south of the ash impoundment, has a similar areal and vertical lithology to line A-A' with the exception that there is no Layer 1 with CCRs. The west end at borings 33 and 27 has thick silty clay and clayey silt deposits (Layer 2) ranging in thickness from 24 to 35 feet, underlain by up to 9 feet of silty, fine to medium sand (Layer 3), and sand and gravel (Layer 4). Moving eastward, Layer 2 is absent at borings 30/31 and Layer 3 is 17 feet thick above Layer 4. At borings 25/26 there is 4 feet of sandy silt (Layer 2) and no Layer 3 above the sand and gravel of Layer 4. Finally, at Boring 36, which is located south of the eastern end of the West Ash Pond System, there are 4 feet of silt (Layer 2) and 6 feet of fine sand (Layer 3) above the sand and gravel of Layer 4.

Cross-Sections C-C' and D-D' both show the thick CCR and fill deposits along the west and central portions of Pond No. 3, respectively, which are underlain by 17 to 25 feet of silty clay and clay of Layer 2. Layer 3 (fine to medium sand) is 8 feet thick at borings 24/L4 on the west side of Pond No. 3 and ranges from 0 feet closer to the river to 10.5 feet thick beneath the middle of Pond No. 3. South of the impoundment at borings 30/31 (cross-section C-C') and borings 25/26 (cross-section D-D') there is no Layer 2 present at borings 30/31 and a 4 foot thickness at borings 25/26. Layer 3 is 17 feet thick at borings 30/31 and is absent at borings 25/26, where Layer 2 lies directly above Layer 4.

3 REGIONAL AND LOCAL HYDROGEOLOGY

3.1 BEDROCK – REGIONAL AND LOCAL

The Pennsylvanian rocks in the region are not considered a municipal or subdivision water supply source (Gibb, 1979). Water-bearing openings are extremely variable from place to place and are best developed near the surface in thin limestones and sandstones, when present within the predominantly shale formation. In the bedrock upland areas away from the Illinois River, farm and domestic water supplies are obtained locally from sandstone and creviced limestone in the upper 250 feet of these rocks (Woller, 1976). When present, the limestone and sandstone units yield less than 10 gallons per minute (gpm) (Visocky et. al, 1985). Water quality within the bedrock varies considerably and it becomes highly mineralized with increasing depth. As a result, the Pennsylvanian bedrock is not a reliable source of groundwater.

The Pennsylvanian rocks generally have low porosity and hydraulic conductivity. The porosity of shale typically ranges from 1 to 20 percent (Walton, 1988). Representative horizontal hydraulic conductivity for shale typically ranges from 5×10^{-6} to 5×10^{-10} centimeters per second (cm/s). Representative vertical hydraulic conductivity ranges for shale are 5×10^{-8} to 5×10^{-12} cm/s (Walton, 1988).

Recharge to the Pennsylvanian rocks is derived locally from vertical leakage through the glacial drift and other unlithified materials that are in turn recharged from precipitation.

Deeper bedrock units beneath the Pennsylvanian rocks and their water-bearing properties (Woller, 1976) are as follows:

- Silurian dolomite, which may provide water to wells in moderate quantities from cracks and crevices, but is too mineralized for most uses.
- Maquoketa Group of Ordovician age composed of non-water-bearing shales and acts as an aquitard between the Silurian dolomite and deeper water-bearing units.
- Cambrian-Ordovician Aquifer (a/k/a Midwest Bedrock Aquigroup), composed of the Ironton-Galesville aquifer at the base of this group up through the Glenwood-St. Peter Sandstones. These formations are the major bedrock aquifer and principal water producing zones in the region capable of yielding moderate quantities of groundwater (Visocky et. al, 1985).

In the region surrounding the site, these bedrock aquifers provide municipal water supply sources. The villages of Granville and Standard, about five miles southeast of the Site, both obtain their water supply from the Galena-Platteville Dolomite and Glenwood-St. Peter Sandstone, with wells ranging in depth from 1,740 to 1,793 feet. Pumping rates range from about 60 to 150 gpm.

As noted earlier, the Pennsylvanian-age Carbondale Formation defines the base of the unlithified deposits (and uppermost aquifer) underlying the West Ash Pond System and is regarded as the first confining unit beneath the uppermost aquifer. Water well logs at the power plant indicate shale bedrock at an elevation of roughly 350. In the vicinity of the Hennepin Power Station the Pennsylvanian rocks have an estimated thickness of approximately 300 to 400 feet. The Pennsylvanian rocks of this area contain little or no usable water and are seldom considered for even domestic water supply purposes due to generally low effective porosity and hydraulic conductivity (Gibb, 1979).

3.2 UNLITHIFIED DEPOSITS - REGIONAL

Regional groundwater flow in the unlithified deposits above the shale bedrock discharges into the Illinois River. Depth to the water table is typically greater than 20 feet below ground surface around the Site. The water table elevation can vary significantly, depending on the river stage. During flood stages, exfiltration from the river may temporarily recharge groundwater close to the river and the water table beneath the West Ash Pond System and adjacent areas of the floodplain may rise to levels mimicking river elevations.

The Henry Formation deposits have high hydraulic conductivity compared to the underlying bedrock. Pump test and specific capacity data were obtained for five high capacity industrial and municipal wells screened in the unlithified deposits along the Illinois River within several miles of the Hennepin Power Station (ISWS, 1989). Hydraulic conductivity of the Henry Formation sand and gravel ranged from 5 x 10^{-2} cm/s to 3 x 10^{-1} cm/s, with a median of 1 x 10^{-1} cm/s. Pumping rates ranged from 125 to 1,570 gpm and the tests were conducted over periods ranging from 30 minutes to 24 hours. Effective porosity typically ranges from 20 to 35 percent for poorly sorted sand and gravel alluvial deposits (Walton, 1988; Fetter, 1980).

Hydraulic conductivity of the alluvial deposits, generally consisting of lower permeability materials (i.e. silt, silty sand, and clay), will typically be several orders of magnitude lower than the more permeable outwash sand and gravel deposits of the Henry Formation. However, no published regional data is available specifically for the shallow alluvial deposits. Silt, clay, and mixtures of sand, silt, and clay typically have horizontal hydraulic conductivity ranging from 10^{-4} to 10^{-7} cm/s (USDI, 1981; Fetter, 1980).

3.3 UNLITHIFIED DEPOSITS – SITE SPECIFIC

The four water-bearing layers encountered at the West Ash Pond System and adjacent areas are: (1) Fill (Unit 1) - CCRs, consisting primarily of fly ash with lesser amounts of bottom ash and slag; (2) fine grained silts and clays (Cahokia Alluvium); (3) fine to medium sands (Cahokia Alluvium); and, (4) sand and gravel with boulders (Henry Formation). The Cahokia Alluvium and Henry Formation together comprise the uppermost aquifer (Unit 2) at the West Ash Pond System and extend from the water table to the bedrock. The underlying shale bedrock has low hydraulic conductivity and defines the lower boundary of the uppermost aquifer. The till is also a confining unit and rests unconformably on top of the shale bedrock; however, the closest this unit has been observed relative to the impoundment is approximately ½ mile south of the Old West Ash Polishing Pond.

Lithologic Layers/Sublayer		Hydrogeologic Unit Designation		
ID	**General Description**	**ID**	**Name**	**Description: Materials**
1a	Mixed Fill, Sand, Silt, Clay	**1**	Fill Unit	Coal Combustion Residuals: Fly Ash, Bottom Ash, Slag
1b	Old West Ash Ponds No. 1 and No. 3 – Fill – Coal Combustion Residuals and Constructed Berms			
2	Alluvial Silts and Clays (Cahokia Alluvium)	**2**	Uppermost Aquifer Unit	Mixed Alluvial Deposits: Clay, Silt, and Sand
3	Alluvial Sands (Cahokia Alluvium)			
4	Glacial Outwash – Sand and Gravel (Henry Formation			Outwash Deposits: Sand and Gravel
5	Till – Loamy and Sandy Diamictons (Wedron or Glasford Formation)	**3**	Till Confining Unit	Silty Clay with Trace Sand
6	Pennsylvanian Bedrock (Carbondale Formation)		Bedrock Confining Unit	Shale, Minor Limestone and Sandstone, Coal

*Till identified at one location – boring for monitoring well 32, located approximately 2,560 feet south of West Ash Pond System. No till identified beneath or within 2,500 feet of impoundment.

As previously discussed, the Henry Formation sand and gravel and the alluvial sands are very permeable, while the alluvial silts and clays have relatively low permeability.

3.3.1 Water Table Elevation and Groundwater Flow

Monitoring wells installed at the West Ash Pond System are shown on Figure 11. Well construction details are provided in Appendix A and summarized on Table 1.

Groundwater elevation data is available beginning in 1993. The Illinois River is the local and regional groundwater discharge area under normal river stage. River stage is usually lowest during the months of August through October. During normal river stage, a slight groundwater mound occurs within the West Ash Pond

System with radial flow north toward the river as well as flow to the southwest that eventually discharges into the river west of the impoundments. Surface water elevations are managed within the conservation area (Donnelley WMA) located west and southwest of the impoundment. Wells 32, 33, and 34 are within the conservation area. The water table contour map for December 10, 2013 (Figure 12) is representative of groundwater flow conditions during normal Illinois River stage elevation of approximately 441 ft.

The river basin experiences annual spring flooding during the months of March, April, May, and sometimes June, while lesser flooding occasionally occurs during autumn. River stage during high precipitation and/or flood events seasonally rises above adjacent groundwater elevations and in low lying areas of the floodplain, particularly within the Donnelley WMA at wells 32, 33, and 34. During these events, the river temporarily recharges the aquifer and groundwater flow direction close to the river reverses. Horizontal gradients across the Site become flat. The water table contour map for March 18, 2015 (Figure 13) is representative of groundwater flow conditions during flood stage, with an approximate river elevation of 446 ft. These groundwater flow reversals are limited in duration and extent.

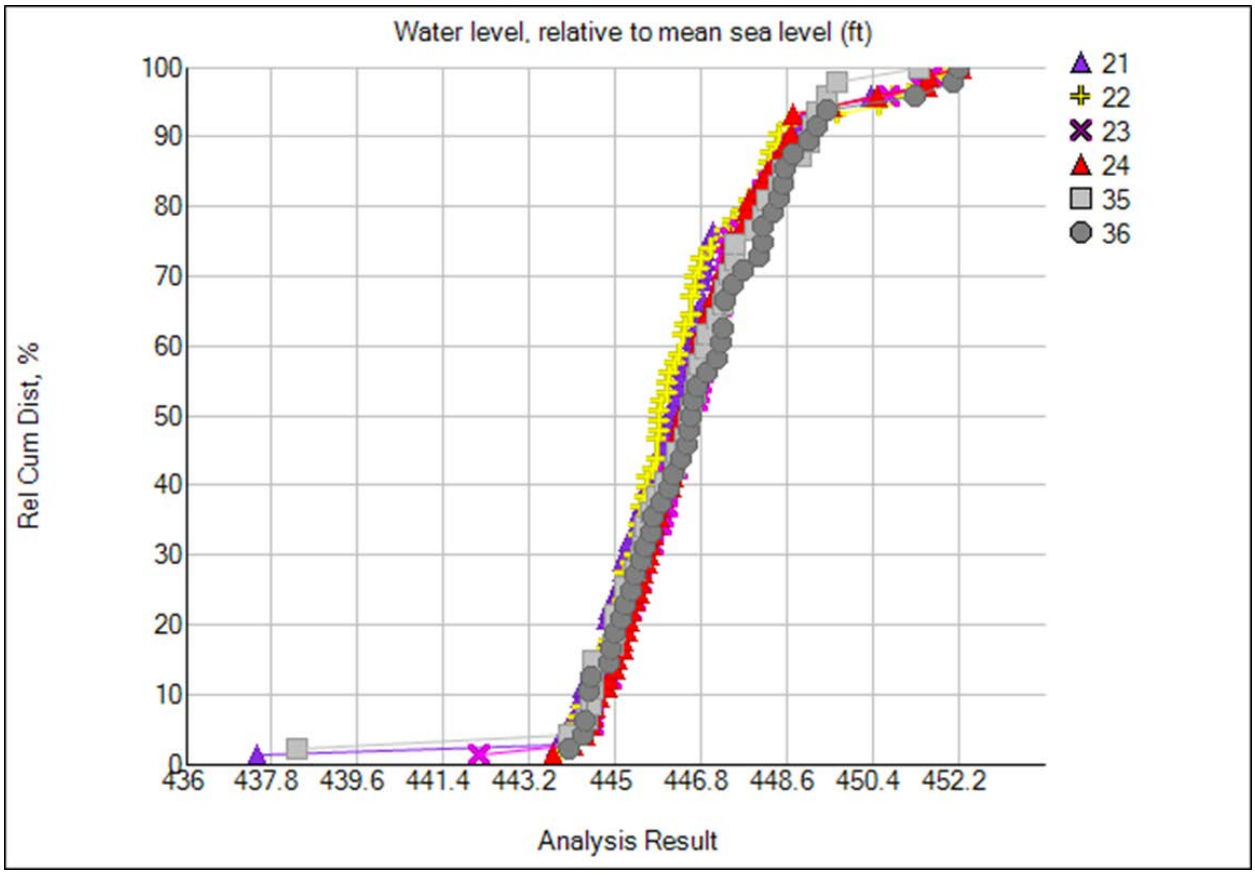
Horizontal hydraulic gradients from the West Ash Pond System to off-site areas ranges from 0.001 foot per foot (ft/ft) during Illinois River flood stage to about 0.005 ft/ft during normal river stage.

Appendix B provides additional water table contour maps prepared for the Closure Work Plan Annual Reports during the years 2013 through 2016.

3.3.2 Saturated Ash

Soil boring logs performed within Pond No. 1 and Pond No.3 (CEC, 2017) indicate the base of the ash is variable but generally rises from west to east. The ash elevation is as low as approximately 441 feet at the west end of Pond No. 3 and rises to 447 feet in the northeast portion of Pond No. 1 (Figure 8).

The Illinois River and the sand and gravel aquifer underlying the West Ash Pond are hydraulically connected. Groundwater hydrographs recorded on the south berm of East Ash Pond No. 2 (Hennepin East Ash Pond System) show that groundwater elevations respond rapidly to higher river elevations associated with major flood events (STMI, June, 1996). As shown in the graph below, the average measured groundwater elevation at the West Ash Ponds (50% occurrence) is 446.3 ft based on 23 years of monitoring data. Ninety percent of measured groundwater elevations (10% occurrence) occur at and below 449.2 ft. The highest groundwater elevations observed have averaged about 451.5 ft.



The above recurrence interval of groundwater elevations is biased low because the monitoring wells are measured on a quarterly basis and measurement dates may not coincide with maximum river flood events.

Based on the above, it can be anticipated that a large portion of the West Ash Pond System base elevations will become saturated when groundwater levels rise to the 10% recurrence interval elevation of 449.2 ft. Illinois River flood elevations are discussed further in Section 3.4.

3.3.3 Hydraulic Conductivity

3.3.3.1 Field Hydraulic Conductivity

Based on the field permeability tests and calculations on seven wells at the West Ash Pond System (Table 2), hydraulic conductivity ranges from 1.2 x 10^{-2} cm/s for the most permeable gravel deposits of the Henry Formation to 1.3 x 10^{-4} cm/s for the least permeable deposits (silt) of the of the Cahokia Alluvium. The geometric mean hydraulic conductivity of wells finished in sand and/or gravel (alluvial or glacial) is 6.0 x 10^{-3} cm/s. The geometric mean hydraulic conductivity of wells finished only in gravel (i.e. Henry Formation) is 1.7 x 10^{-2} cm/s. The lowest permeability occurred in the alluvial silt, with a hydraulic conductivity of 1.3 x 10^{-4} cm/s. The hydraulic conductivity test analysis and results are provided in Appendix C1.

Pump test data from the fire well installed at the power plant in 1968 was also available to estimate the permeability of the Henry Formation. This fire well is located at the southwest corner of the plant and was drilled to a depth of 112 feet, terminating on shale. The lower 30 feet of the well is screened within unlithified deposits. The well log is contained in 'Water Well Survey' (Kelron/NRT; June 3, 2009). The pump test hydraulic conductivity result reported by Mathes (1983) was 1.3 x 10^{-1} cm/s (Table 2).

3.3.3.2 Laboratory Hydraulic Conductivity

Two samples were collected by AECOM for laboratory hydraulic conductivity tests (ASTM D 5084). HEN-B010 was located on the south berm of Pond 3. HEN-B017 was located on the west berm of the Old West Polishing Pond.

Sample Location	Sample Depth (ft bgs)	Description	Hydraulic Conductivity (cm/sec)
HEN-B010	10.0 ft – 11.5 ft	Very dark gray fly ash with sand and gravel	1.16×10^{-5}
HEN-B017	5.0 ft – 7.0 ft	Very dark gray lean clay with sand	6.79×10^{-7}

Laboratory hydraulic conductivity test results are provided in Appendix C2. Other geotechnical test results on soil samples are provided in Appendix D.

3.3.3.3 Groundwater Velocity

Groundwater velocity was calculated in the vicinity of the West Ash Pond System under normal flow conditions where the aquifer discharges to the Illinois River using the following formula:

$$\text{velocity} = \frac{(\text{hydraulic conductivity})\ (\text{hydraulic gradient})}{\text{effective porosity}}$$

For representative conditions existing in June and September, 2013 the calculated velocities were as follows:

Flow Path	Average Hydraulic Conductivity (cm/sec)	Hydraulic Gradient	Effective Porosity	Velocity (ft/day)[1]
Well 21 to Well 34	1.7×10^{-2}	0.005	0.22	1.1
Well 21 to Well 34	6.0 x 10-3	0.001	0.22	0.1
Well 27 to Well 33	6.0×10^{-3}	0.005	0.22	0.4
Well 27 to Well 33	1.7×10^{-2}	0.001	0.22	0.2

[1] cm/sec x 2,835 = feet/day

For the range in hydraulic conductivities and hydraulic gradients observed, the calculated velocities away from the impoundment range from 0.1 to 1.1 ft/day (37 to 401 ft/yr).

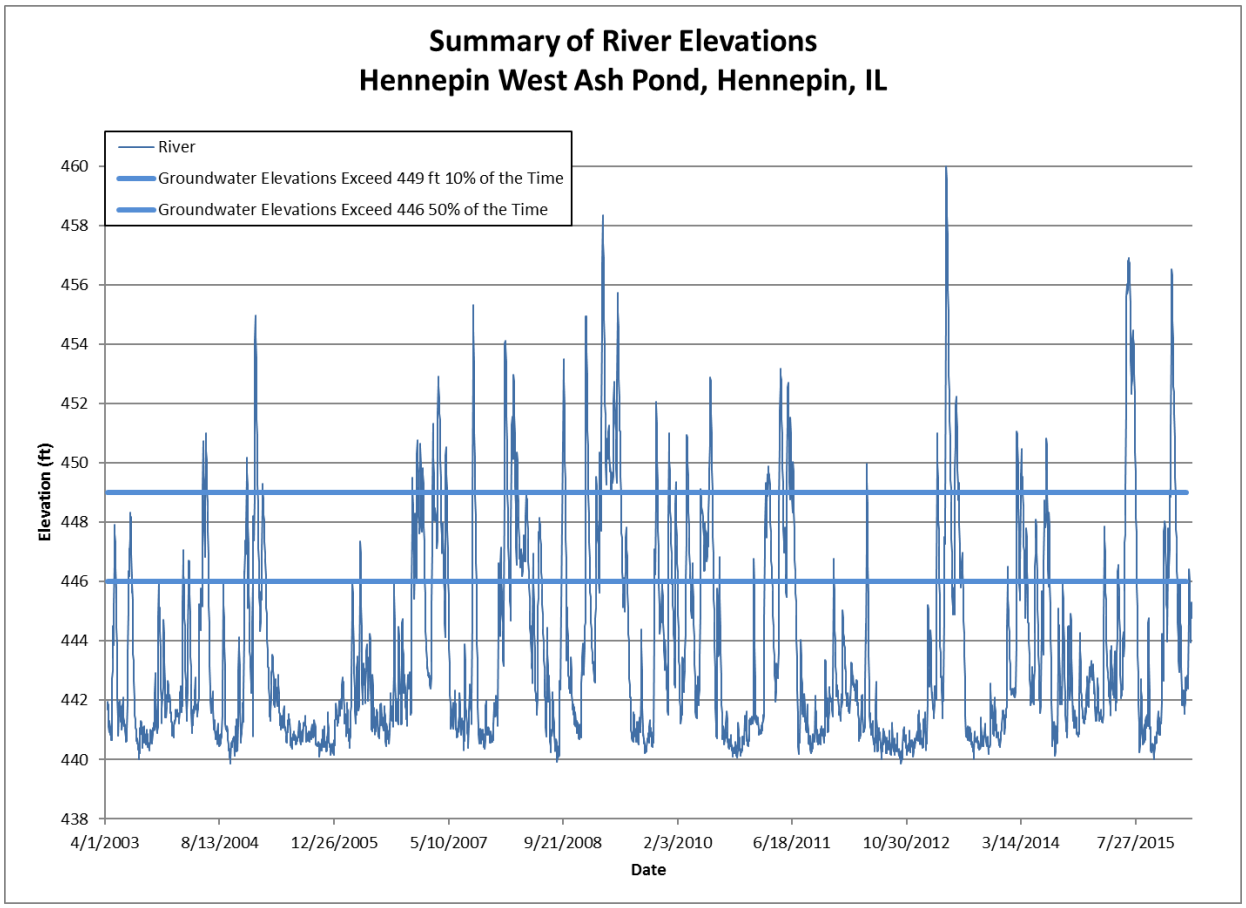
3.3.4 Groundwater Classification

Per Illinois Administrative Code (IAC) Title 35, Section 620.210, groundwater within the Uppermost Aquifer at the West Ash Pond System meets the definition of a Class I, Potable Resource Groundwater based on the following criteria:

- Groundwater in the uppermost aquifer extends 10 feet or more below the land surface
- Hydraulic conductivity exceeds the 1 x 10-4 cm/s criterion (Table 2)

3.4 SURFACE WATER HYDROLOGY

The predominant surface water body in the region is the Illinois River and associated lowland backwater lakes. The Illinois River is located directly adjacent to and down-gradient from the West Ash Pond System under normal flow conditions. River elevation data collected at Hennepin Power are shown below for the period 2003 through 2016.



Bordering the north perimeter of the west impoundment, the river has a normal pool elevation of about 441 ft. A FEMA Flood Insurance Rate Map for Putnam County (Map No. 17155C0015E; Effective Date: February 4, 2011) is attached in Appendix E and can also be viewed online at: http://www.illinoisfloodmaps.org/DFIRMpdf/putnam/putnam_fin_0025.jpg.

The base flood elevation value of 462 feet is located through the center of the Old West Ash Pond's Pond No. 3. As identified on the 2011 FEMA map, the floodway boundary encompasses the entire area of the Old West Ash Pond except for Pond No. 1. However, the berms of the impoundment were raised in 1979 and 1988-1989, with only the Old West Polishing Pond remaining subject to flooding at the 462 foot elevation. The flood hazard areas shown on the map are defined as those areas subject to inundation by the 1% annual chance flood (i.e. 100-year flood), also known as the base flood, that has a 1% chance of being equaled or exceeded in any given year.

3.5 WATER WELL SURVEY

A comprehensive water well survey was conducted by NRT and Kelron (2009a) for a 2,500-foot radius around the entire Hennepin Power Station property boundary, inclusive of the West Ash Pond System (Appendix F). Based on State of Illinois records obtained from the Illinois EPA, Illinois State Geological Survey (ISGS), and Illinois State Water Survey (ISWS) there are only two wells located outside of the Hennepin Power Station property boundary and within 2,500 feet of the West Ash Pond System. The two wells, constructed in 1844 and 1922 to depths of 30 and 17 feet bgs, respectively, according to State of Illinois records, have been verified and were most likely abandoned decades ago. There are no homes, farms or other potential users present at the two locations. There are also no public water supply (PWS), community water supply (CWS) or non-CWS wells or wellhead protection areas (WHPAs) within 2,500 feet of the West Ash Pond System.

Within the plant property boundary, and within 2,500 feet of the West Ash Pond System, there are four wells owned by DMG, all of which are non-potable and non-contact industrial wells.

An assessment of the potential for groundwater impact to water wells, as identified in the water well survey (NRT and Kelron, 2009b) demonstrated that there are no existing off-site water wells, potable or non-potable, that are likely to be impacted by groundwater from the West Ash Pond System or the Hennepin Power Station.

4 GROUNDWATER QUALITY

4.1 SUMMARY OF GROUNDWATER MONITORING ACTIVITIES

4.1.1 Groundwater Monitoring – Illinois EPA Closure Work Plan

Groundwater sampling at the West Ash Pond System was initiated in 1983; however, consistent data collection began in 1996 in accordance with the Closure Work Plan approved by the Illinois EPA on November 8, 1996. The 1996 Closure Work Plan required DMG to sample groundwater quarterly at the West Ash Pond System and to submit the data in an annual report. Requested modifications to the 1996 Closure Work Plan were approved by the Illinois EPA on January 27, 2005 and included the following:

- Reduce monitoring frequency for wells on a quarterly schedule to semiannually;
- Reduce reporting of data to the Illinois EPA on disc to semiannually; and,
- Remove parameters from the monitoring program that do not have a groundwater standard, with the exception of water elevation.

The current Illinois EPA groundwater monitoring program consists of collecting samples from 3 background wells (32, 33, 34) and 9 downgradient wells (21 through 27, 30, 31). Samples are collected semi-annually except for background wells 33 and 34, which are sampled annually. Groundwater samples are analyzed for the following parameters:

Field Parameters		
Ph	**Temperature**	
Specific Conductivity	**Groundwater Elevation (ft)**	
Laboratory Parameters		
Boron (Dissolved)	**Iron (Dissolved)**	**Sulfate (Total)**
Chloride (Total)	**Manganese (Dissolved)**	**Total Dissolved Solids (TDS)**

Time concentration plots showing the results of the above monitoring are provided in Appendix G1. Four additional monitoring wells (L3, L5, 35 and 36) have been monitored periodically for groundwater elevation only. The monitoring well locations are shown on Figure 11.

Groundwater monitoring results are reported to the Illinois EPA annually in accordance with the approved Closure Work Plan. The most recent data and analysis were submitted in '*2016 Closure Work Plan Annual Report* (NRT, October 21, 2016).

Additional groundwater monitoring was initiated for four quarters (June [Q2] 2013 through March [Q1] 2014) at the above 12 well locations to assess compliance with the IAC 35 Part 620 Section 410 *Groundwater Quality Standards for Class I: Potable Resource Groundwater*. Sampling was conducted for an expanded list of parameters that included the following:

Field Parameters	
Ph	**Temperature**
Specific Conductivity	**Turbidity**

Laboratory Parameters			
Inorganics (Total)			
Chloride	Fluoride	Nitrite	Sulfate
Cyanide	Nitrate	Perchlorate	TDS
Metals (Total and Dissolved)			
Antimony	Cadmium	Lead	Silver
Arsenic	Chromium	Manganese	Thallium
Barium	Cobalt	Mercury	Vanadium
Beryllium	Copper	Nickel	Zinc
Boron	Iron	Selenium	
Organic Compounds			
Volatile Organic Compounds	Polychlorinated Biphenyls (PCBs)		
Semi-Volatile Organic Compounds	Specialized Organic Parameters: Endohall, Ethyl Dibromide (EDB) and 1,2-Dibromo-3-Chloropropane (DBCB)		
Chlorinated Pesticides			
Chlorinated Herbicides			

The groundwater quality results for the above field, inorganic and organic parameters listed in IAC 35 Part 620 Section 410 (except for Radium 224/226) for the four quarters of monitoring are provided in Appendices F2 and F3, respectively.

4.1.2 40 CFR Part 257 Monitoring

Groundwater data collection under the CCR Rule was initiated in fourth quarter, 2015. The CCR Rule monitoring network consists of background/upgradient monitoring wells 32 and 34, and downgradient monitoring wells 21, 22, 23, 24, 35, and 49. Monitoring well 49 was installed by NRT in July, 2015 (Appendix A3) on the north berm of Old West Ash Pond to supplement the CCR Rule groundwater monitoring network. Monitoring of this well commenced in 2016. Parameters tested under the initial CCR Rule groundwater monitoring requirements include Appendix III and Appendix IV parameters (see below). All existing groundwater monitoring wells are measured at least annually for groundwater elevation.

40 CFR Part 257 Monitoring			
Appendix III Parameters (Total, except TDS)			
Boron	Chloride	pH	TDS
Calcium	Fluoride	Sulfate	
Appendix IV Parameters (Total)			
Antimony	Cadmium	Lead	Selenium
Arsenic	Chromium	Lithium	Thallium
Barium	Cobalt	Mercury	Radium 226/228
Beryllium	Fluoride	Molybdenum	
Field Parameters			
Dissolved Oxygen	Specific Conductivity	Turbidity	pH

Data collected under the CCR Rule groundwater monitoring program will be available when CCR reporting begins in January 2018. Following the completion of eight quarterly sampling events, the monitoring program will be modified so that the analytical parameters and sampling frequency are appropriate to the objectives and requirements of the CCR Rule.

4.2 GROUNDWATER MONITORING RESULTS AND ANALYSIS – ILLINOIS EPA CLOSURE WORK PLAN PARAMETERS

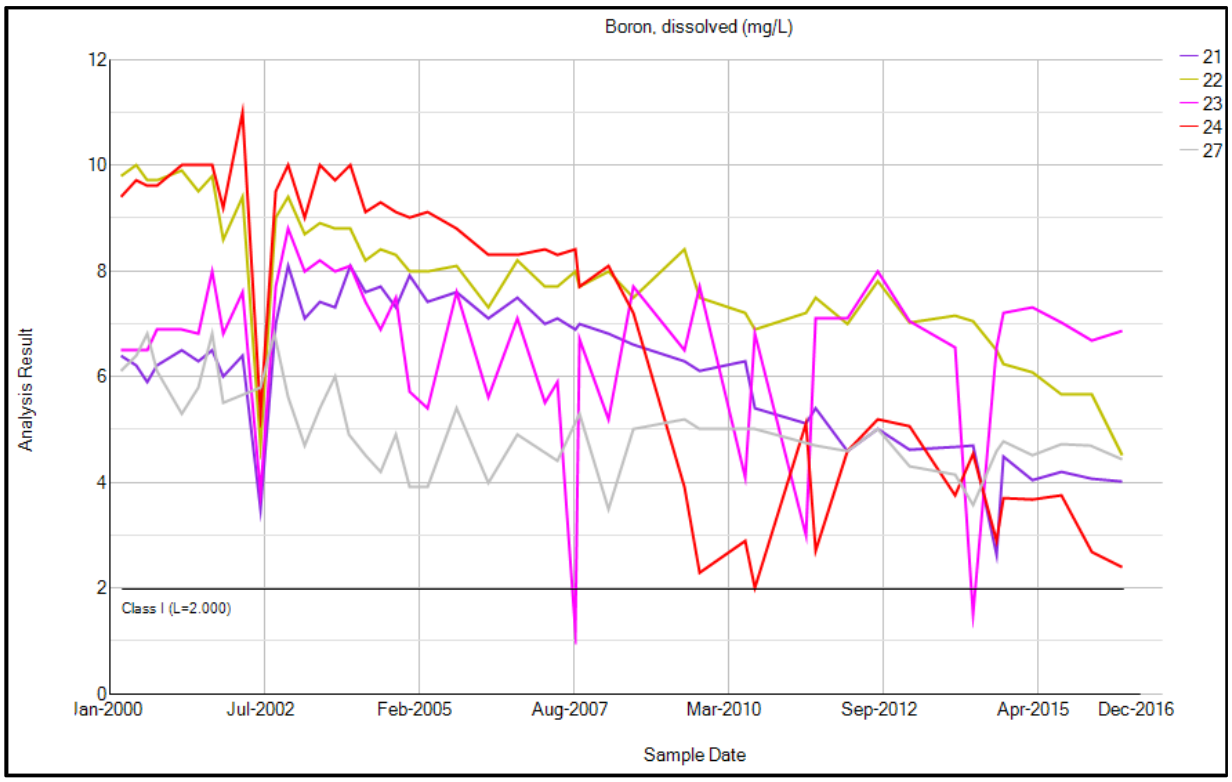
A summary of the number of groundwater quality exceedances at each well, and the date of the last exceedance, are provided in Table 3. The parameters observed in groundwater with exceedances of Class I standards during the most recent 2016 Closure Work Plan sampling event included boron, iron, manganese and sulfate. Time

versus parameter concentration plots for the Illinois EPA parameters over the period 2005 through 2016 are provided in Appendix G1. These parameters are discussed in greater detail below.

4.2.1 Boron

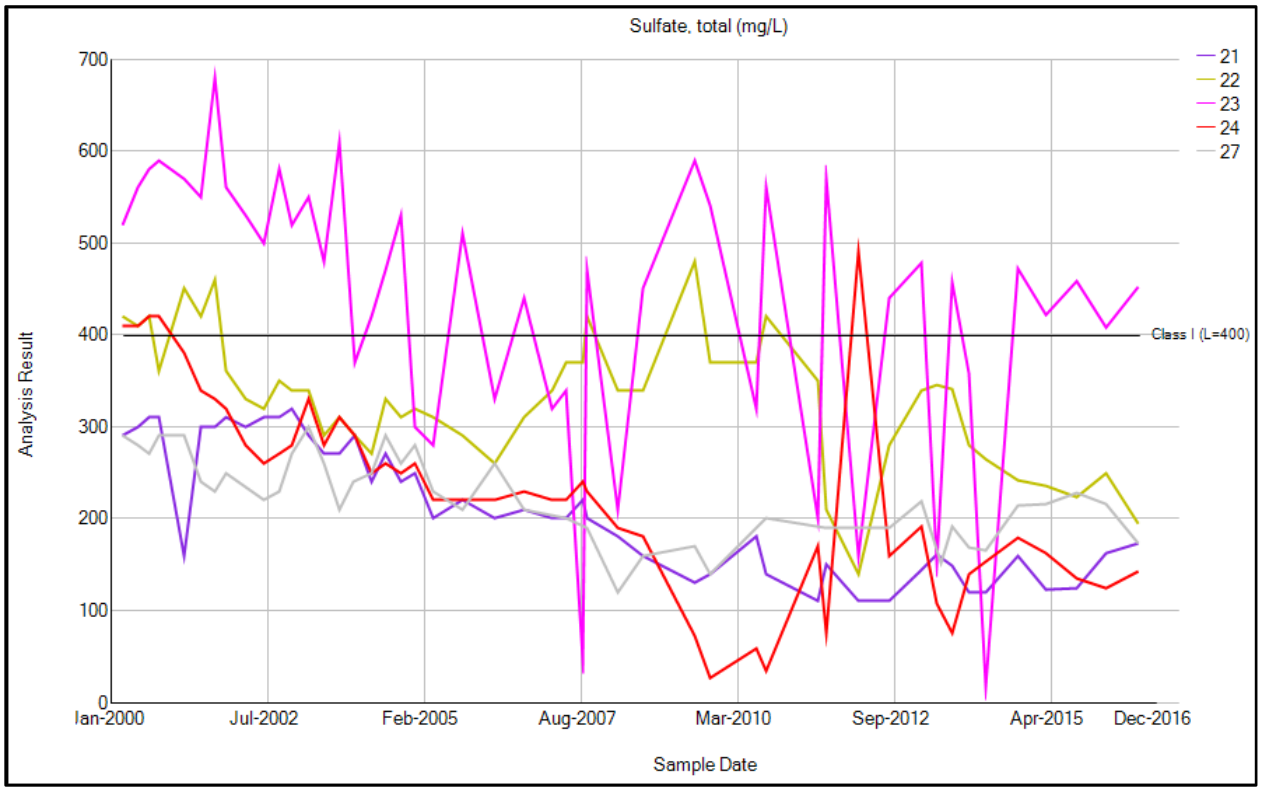
Boron is a primary indicator parameter for CCR leachate impacts on groundwater quality. Boron exceeds the 2 milligrams per Liter (mg/L) standard at 5 of the 12 monitoring wells as shown on Figure 14. Exceedances occur in wells 21 through 24 on the West Ash Pond System berms and well 27, located south of the Old West Polishing Pond. None of the other monitoring wells have had a boron exceedance since 1996, or prior to the removal of the west impoundment from service.

Boron concentrations in downgradient monitoring wells 21 through 24 and 27 have been trending downward (see Table 4 and graph below) since the impoundment was removed from service in 1996. For the period of January 2000 – September 2016, the five downgradient wells have had downward (i.e. negative) concentrations trends:



4.2.2 Sulfate

Sulfate is also a primary indicator parameter of CCR leachate impacts on groundwater quality. Since the impoundment was removed from service in 1996, sulfate concentrations at the five downgradient wells (21 through 24 and 27) have been trending downward (see graph below) and decreased from their peak by 22 to 69 percent (Table 4). Exceedances of the Class I groundwater standard for sulfate are continuing to be observed at well 23 between the river and the impoundments. Sulfate concentrations in the four wells to the south (wells 25, 26, 30, and 31) have also declined by 38 to 54 percent from their peak (i.e. post-1996) concentrations.



4.2.3 Iron

Iron is a redox-sensitive parameter that typically has low concentration in oxic groundwater and elevated concentration in reduced groundwater. Iron concentrations greater than 1 mg/L in neutral pH groundwater are indicative of strongly reduced conditions.

Iron concentrations in wells 22 and 23 are typically lower than 0.2 mg/L, indicating oxic conditions are prevalent at these monitoring points. Conversely, iron concentrations were typically greater than 2 mg/L in monitoring wells 21 and 34, indicative of persistent strongly reducing conditions. Other wells had variable iron concentrations, indicating that redox conditions varied over the course of the year. Well 25 had its only recorded exceedance in June 2013 during a period of flooding along the Illinois River. Other wells (22, 23, 26, 27, 30, 31, 32) also had unusually high iron concentrations during this period, suggesting that flood conditions affected geochemical conditions and iron concentrations,

Iron has been monitored since 1995. Concentrations higher than the Class I standard were frequently observed at wells 24 (1995 through 2000), 33 (through 2013), and 34 (through 2016), and there was only one exceedance in another monitoring well, well 26 in 2005. Based on concentrations before and after the exceedance at well 26, this value appears to be an outlier (Table 3). These observations indicate that the exceedance observed in well 25 in Q2 2013 likely represents an unusual event, while the exceedances in background wells 33 and 34 are normal.

Elevated concentrations of iron do not correlate to the CCR leachate indicator parameters of boron and sulfate, and are not caused by a release from the West Ash Pond System. The observed variability in iron concentrations in groundwater sampled from different parts of the area are controlled by variations in groundwater geochemistry rather than a release from the West Ash Pond System.

4.2.4 Manganese

Like iron, manganese is controlled by geochemical conditions, and its concentration distribution in groundwater is not due to a release from the West Ash Pond System. Elevated concentrations of manganese do not correlate

to CCR leachate indicator parameters boron and sulfate. Exceedances of the manganese Class I groundwater quality standard (0.15 mg/L) occurred in 2016 at downgradient monitoring well 23 as well as south wells 27 and 31 and background well 34.

These highly variable manganese concentrations are due to variable geochemical conditions rather than a release from the West Ash Pond System. Detailed discussions of the manganese geochemistry in wells at the West Ash Pond System are provided in the EPRI manganese research report submitted to the Illinois EPA on November 6, 2002 (EPRI, 2002).

4.2.5 pH

Median pH values at all 12 monitoring wells range from 6.88 to 7.71. There have been no exceedances of Class 1 Groundwater upper (pH 9.0) or lower (pH 6.5) standards at any monitoring wells since 2010 (Table 5).

4.2.6 TDS

Total Dissolved Solids (TDS) concentration trends generally mirror those of sulfate, which is a major anion that affects TDS concentrations. None of the wells monitored have exhibited a TDS exceedance of Class I standard (1,200 mg/L) since 1993, prior to closure of the West Ash Pond System in 1996 (Table 3).

4.2.7 Chloride

Chloride has not exceeded the 200 mg/L Class I standard in 19 years of monitoring except in one well in one sampling event. This exceedance occurred in 2013 (Table 3) and is an anomaly unrelated to any groundwater quality impacts attributable to the West Ash Pond System.

4.3 GROUNDWATER MONITORING RESULTS AND ANALYSIS – IAC 35 PART 620.410 PARAMETERS

Of the additional inorganic parameters monitored in 2013 and 2014, arsenic and selenium were detected above Class I groundwater quality standard in downgradient wells and may be related to CCRs. Arsenic also occurs in a background well and selenium was observed only one time at one well. Nitrate and lead exceedances occurred in background and/or south monitoring wells and are not related to CCR leachate. These parameters are discussed in greater detail below

4.3.1 Arsenic

Arsenic concentrations exceeded the Class I standard of 0.01 mg/L at three wells: downgradient wells 21 and 24, with maximum concentrations of 0.0104 and 0.030 mg/L, respectively, and background well 33 had one exceedance with a concentration of 0.017 mg/L (Appendix G2). These three wells also had relatively high iron concentrations. High iron concentrations are indicative of reduced redox conditions in groundwater, and arsenic concentrations in groundwater can be naturally-occurring under these conditions. The arsenic concentration in background well 33 represents a naturally occurring condition. The two other downgradient monitoring wells (22 and 23), where iron concentrations are relatively low, suggesting less-reducing or perhaps oxic conditions, had arsenic concentrations below the method detection limit (MDL) during all four quarters. These observations suggest that the arsenic observed in wells 21 and 24 are naturally occurring rather than due to arsenic release from the West Ash Pond System.

4.3.2 Selenium

All samples analyzed from 12 monitoring wells during the four sampling events were below the MDL of 0.04 mg/L except in the December 2014 groundwater sample from well 24, located adjacent to the impoundments (Appendix G2). The observed concentration of 0.073 mg/L exceeded the Class I standard of 0.05 mg/L. This isolated detection near the detection limit indicates selenium is not a constituent of concern.

4.3.3 Lead

Out of 47 groundwater samples collected from 12 monitoring wells during the four sampling events, lead was detected once above the MDL (0.0075 to 0.008 mg/L) in the June 2013 groundwater sample from south monitoring well 25 at a concentration of 0.009 mg/L (Appendix G2). The Class I standard for lead is 0.0075 mg/L. Groundwater sampled during the June 2013 event at this well also had unusually high concentrations of

iron and manganese. The one-time lead exceedance at well 25 is related to geochemical changes in groundwater because of flooding along the Illinois River. The West Ash Pond System was not the source of lead observed in this sample.

4.3.4 Nitrate

Nitrate concentrations in groundwater exceeded the Class I standard of 10 mg/L at south monitoring wells 25 and 26 during at least one quarterly sampling event, with maximum concentrations of 12.2 and 15.1 mg/L (Appendix G2). Nitrate occurrence in groundwater at the West Ash Pond System is related to widespread use of nitrogen fertilizers upgradient of the site. Nitrate is a widespread and nonpoint source of contamination to shallow groundwater in the region and is not related to CCRs at the West Ash Pond System.

4.3.5 Other Inorganic Water Quality Parameters

None of the inorganic parameters listed in IAC 35 Part 620.410 monitored in 2013-2014 (Appendix G2) and not discussed above have exceedances of Class I groundwater standards that occur at downgradient monitoring wells at detectable or significant concentrations, or have concentrations in downgradient wells that can be attributed to CCR-impacts related to the West Ash Pond System. These parameters include the following:

4.3.5.1 Fluoride

No groundwater samples at any of the monitoring wells exceeded the Class I groundwater standard of 4 mg/L. Fluoride concentrations in the downgradient, south, and background monitoring well groups were within a similar range. Fluoride concentrations in groundwater in the vicinity of the West Ash Pond System are naturally occurring and not related to CCRs.

4.3.5.2 Cyanide (Total)

Cyanide was detected twice at the detection limit in the December 2013 and March 2014 groundwater sample from downgradient monitoring well 24 at a concentration of 0.008 and 0.007 mg/L, respectively. The Class I standard for cyanide is 0.2 mg/L. Cyanide is not a constituent of concern.

4.3.5.3 Perchlorate

Perchlorate was analyzed during the first quarterly sampling event, conducted in June 2013. Perchlorate was not detected at concentrations above the MDL of 0.004 mg/L. The Class I groundwater standard for perchlorate is 0.0049 mg/L. Perchlorate is not a constituent of concern.

4.3.6 Trace Elements

The following parameters were not detected above their MDL during the 2013 and 2014 sampling events:

Parameter	Method Detection Limit (MDL) (mg/L)	Class I Groundwater Standard (mg/L)
Antimony	0.005	0.006
Beryllium	0.001	0.004
Cadmium	0.002	0.005
Chromium	0.01	0.1
Cobalt	0.01	1.0
Copper	0.01	0.65
Mercury	0.0002	0.002
Silver	0.01	0.05
Thallium	0.002	0.002

Of the 47 samples collected, the following parameters were detected above their MDLs during the 2013 and 2014 sampling events. None of these parameters exceeded their Class I groundwater standards.

Parameter	Number of Detections	Maximum Concentration Detected (mg/L)	Class I Groundwater Standard (mg/L)
Barium	47	0.20	2.0
Nickel	1	0.0127	0.1
Vanadium	1	0.011	0.049
Zinc	9	0.048	5.0

4.3.7 Organic Water Quality Parameters

Organic water quality parameters listed in IAC Part 620, Section 410 were sampled and analyzed in all four quarters at the 12 monitoring wells. Laboratory analytical results for groundwater samples are summarized in Appendix G3. A summary of all detected organic parameters is listed by monitoring well and date in the table below. Although a few organic parameters were detected at eight of the twelve monitoring wells, there were no exceedances of the Class I groundwater standards and over 50 percent of the detected parameters were below quantitation limits (i.e. J-flag on the lab report). When detected, the parameters concentrations were well below Class I groundwater standards.

Detected Organic Parameters (mg/L)

Well Number	Parameter	Class I Standard (mg/L)	Q1 (June 2013)	Q2 (Sept. 2013)	Q3 (Dec. 2013)	Q4 (March 2014)
Background Monitoring Wells						
32	Acetone	6.3	-	0.007 J	-	-
	Atrazine	0.003	0.0001 J	-	0.00006 J	-
	Naphthalene	0.14	-	-	0.00013	-

22	Bis 2-ethylhexyl phthalate	0.006	-	-	-	0.005 J
23	None	NA	-	-	-	-
24	Acetone	6.3	-	0.006 J	-	-
	1,4-Dioxane	0.0077	-	-	-	0.00069 J
	Phenol	0.1	-	0.052	-	-
	1,1,1-Trichloroethane	0.2	-	0.001 J	-	0.0084
	Trichlorofluoromethane	2.1	-	-	-	0.0044 J

Well Number	Parameter	Class I Standard (mg/L)	Q1 (June 2013)	Q2 (Sept. 2013)	Q3 (Dec. 2013)	Q4 (March 2014)	Well Number
South Monitoring Wells							
25	None	NA	-	-	-	-	
26	Atrazine	0.003	0.0004	-	0.00008 J	-	
27	Atrazine	0.003	0.0005	0.0001	0.00011	0.00008 J	
30	None	NA	-	-	-	-	
31	Atrazine	0.003	0.0002	-	0.0001	-	
	Naphthalene	0.14	0.00011	-	-	-	--

Notes:

- - Not detected in sample.
- J Analyte detected below quantitation limits.
- NS No sample collected on the date indicated due to flooding along the Illinois River.
- NA Not applicable. No organic parameters tested had a detected concentration in groundwater at this monitoring well during the four quarters of sampling from June 2013 through March 2014.

No detected organic parameters listed in the above table exceed their respective Class I groundwater standards as listed in IAC Part 620 Section 410.

The most frequently detected compounds were acetone, atrazine, 1,4-Dioxane, and naphthalene. Acetone was detected below quantitation limits in four samples, all collected on the same date during the 2nd quarter of monitoring in September 2013. The acetone is most likely a laboratory contaminant as it was only detected during one sampling event at concentrations below quantitation limits, and with no re-occurrence.

Atrazine is a common herbicide and was detected in two background monitoring wells (32 and 33) and three south monitoring wells (26, 27, and 31). Atrazine was detected in samples from two or more quarterly events at four of the five wells where it was reported. No downgradient wells had a detected concentration of Atrazine.

The compound 1,4-Dioxane was detected during one or more quarters in samples from three monitoring wells – background wells 32 and 34 and downgradient well 24.

Naphthalene was detected near the MDL of 0.0001 mg/L in samples from three monitoring wells – background wells 32 and 33 and south monitoring well 31. There were no detected concentrations of naphthalene in downgradient wells.

Four other organic compounds were detected at a lower frequency and at concentrations below their respective Class I groundwater standards: Bis 2-ethylhexyl phthalate, 1,1,1-trichloroethane, trichlorofluoromethane and phenol.

5 POTENTIAL IMPACTS TO THE ILLINOIS RIVER

As discussed previously in this report, groundwater flows north/northeast during baseflow conditions and groundwater from below the Hennepin West Ash Pond System discharges to the Illinois River. During baseflow conditions the groundwater discharging to the Illinois River has the potential to impact the river, increasing concentrations of the two primary CCR indicators for this site, boron and sulfate. Calculations for the potential impact from groundwater discharge to the Illinois River are provided in the tables below for boron and sulfate, respectively. The 7-day, 10-year low flow event (i.e. 7Q10) was used to estimate flow volume in the river and a mixing zone of 50 feet was used to determine dilution of the groundwater concentrations.

Conservative assumptions were used to calculate the resulting change in concentration to the Illinois River. Based on the calculations, groundwater discharge to the Illinois River could potentially increase concentrations of boron by 0.0034 mg/L and sulfate by 0.19 mg/L. Both concentrations are below their respective detection limits reported by the laboratory, indicating that changes in concentration would likely not be detected and impacts would be negligible.

Mixing Calculation Showing Effect of Boron Loading on Illinois River Quality at Low Flow

Baseflow		3515	cfs	Source: NPDES Permit IL0001554
	=	8.6E+09	L/day	
Boron loading rate				
Maximum Boron Concentration in Groundwater (CAvg)		8.5	mg/L	Maximum Concentration Well 23 - 6/2016
Hydraulic Conductivity (between Ash Complex and River)		0.0060	cm/s	Geometric mean of sand and gravel (Table 3)
Hydraulic Gradient		0.0050		Maximum included in report (Subsection 3.3.3.3)
Aquifer Thickness		50	ft	Estimated maximum depth of impacts in sand and gravel
Length of Ponds (max length, west to east)		2,500	ft	
Q = KIA				
K = Max Hydraulic Conductivity		2.0E-04	ft/s	
I = Hydraulic Gradient		0.00500		
A = Cross-Sectional Area		125,000	ft^2	
Q (per second)		0.12303	cfs	
Q (per day)		301,007.48	L/day	
Loading Rate (L)		2.6E+06	mg/day	= Cmax * Q
	L =	5.63	lb/day	
Boron concentration increase in Illinois River at low flow due to loading from West Ash Pond System				
	d_B =	3.0E-04	mg/L	= $L/Q_{7,10}$
Boron concentration increase near-shore in Illinois River at low flow due to loading from the West Ash Pond System				
Assumes loading distributed within 75 feet of shoreline		0.0034	mg/L	River is approximately 850 ft wide
Typical boron laboratory detection limit		0.01	mg/L	Source: Teklab Report 3/2016

Conclusion:

The calculated boron concentration increase in the Illinois River at ***low flow*** due to groundwater loading from the West Ash Pond System is less than half the typical boron detection limit, indicating that increases due to impacted discharge would not be detectable. These calculations indicate that the effects of boron loading in groundwater discharge to the Illinois River are negligible.

Mixing Calculation Showing Effect of Sulfate Loading on Illinois River Quality at Low Flow

Baseflow		3515	cfs	Source: NPDES Permit IL0001554
	=	8.6E+09	L/day	
Sulfate loading rate				
Maximum Sulfate Concentration in Groundwater (CAvg)		483	mg/L	Maximum Concentration Well 23 - 6/2016
Hydraulic Conductivity (between Ash Complex and River)		0.0060	cm/s	Geometric mean of sand and gravel (Table 3)
Hydraulic Gradient		0.0050		Maximum included in report (Subsection 3.3.3.3)
Aquifer Thickness		50	ft	Estimated maximum depth of impacts in sand and gravel
Length of Ponds (max length, west to east)		2,500	ft	
Q = KIA				
K = Max Hydraulic Conductivity		2.0E-04	ft/s	
I = Hydraulic Gradient		0.00500		
A = Cross-Sectional Area		125,000	ft^2	
Q (per second)		0.12303	cfs	
Q (per day)		301,007.48	L/day	
Loading Rate (L)		1.5E+08	mg/day	= Cmax * Q
	L =	319.85	lb/day	
Sulfate concentration increase in Illinois River at low flow due to loading from West Ash Pond System				
	d_B =	1.7E-02	mg/L	= $L/Q_{7,10}$
Sulfate concentration increase near-shore in Illinois River at low flow due to loading from the West Ash Pond System				
Assumes loading distributed within 75 feet of shoreline		0.1916	mg/L	River is approximately 850 ft wide
Typical sulfate laboratory detection limit		5	mg/L	Source: Teklab Report 3/2016

Conclusion:

The calculated sulfate concentration increase in the Illinois River at ***low flow*** due to groundwater loading from the West Ash Pond System is an order of magnitude less than the typical sulfate detection limit, indicating that increases due to impacted discharge would not be detectable. These calculations indicate that the effects of sulfate loading in groundwater discharge to the Illinois River are negligible.

6 CONCLUSIONS

Data acquired from prior investigations and activities at the West Ash Pond System were incorporated into this Hydrogeologic Site Characterization Report to provide a complete physical and chemical evaluation of the impoundments and vicinity. The site characterization findings are summarized below:

- The West Ash Pond System encompasses two ash ponds of approximately 30.4 acres total and were operational from 1952 through 1996.
- Three hydrogeologic units are present at the site:
  - Fill Unit, the uppermost unit, is comprised of CCRs – fly ash, bottom ash, and minor slag. In some areas, such as constructed berms, the Fill Unit has CCRs mixed with sand, silt, and clay. CCRs of the Fill Unit are found in all ponds – Old West Ash Pond (including Pond No. 1, Pond No. 3) and Old West Polishing Pond.
  - Uppermost Aquifer Unit is comprised of mixed alluvial deposits (clay, silt, and sand) which overlie coarser grained outwash sand and gravel deposits. This unit is the uppermost aquifer and primary groundwater transport pathway in the vicinity of the West Ash Pond System.
  - Bedrock Confining Unit is defined by Pennsylvanian age shale with minor layers of limestone, sandstone, and coal. This low permeability unit defines the lower boundary of the Uppermost Aquifer Unit.
- Median saturated ash thickness for the period of 2003 through 2013 ranged from no saturated ash at the northwest corner of Pond No. 1 (eastern portion of the Old West Ash Pond) to 6.6 feet of saturated ash at the western edge of Pond No. 3 (western portion of the Old West Ash Pond). Based on a representative median groundwater elevation of 447 feet and average base of ash elevation of 444 feet within Pond No. 3, the median saturated ash thickness is three feet. Conversely, since maximum groundwater elevations measured near Pond No. 1 are below the base of ash, it can be concluded that there is typically no saturated ash within Pond No. 1.
- The Illinois River is located directly adjacent to and downgradient from the West Ash Pond System. Flood events typically occur in March, April, May, and sometimes June, while lesser flooding occasionally occurs during autumn. Only the Old West Polishing Pond is subject to 100-year flooding at the base flood elevation value of 462 feet.
- The Illinois River is the regional groundwater discharge area, but localized groundwater flow directions that are westward and southward from the West Ash Pond System are present due to localized groundwater mounding under the impoundments. River stage during high precipitation and/or flood events seasonally rises above adjacent groundwater elevations and in low lying areas of the floodplain. During these events the river temporarily recharges the aquifer and groundwater flow direction close to the river reverses.
- Within the Uppermost Aquifer, the geometric mean hydraulic conductivity of wells finished in sand and gravel is 6×10^{-3} cm/s versus 2×10^{-3} cm/s for wells finished predominantly in gravel. The lowest measured hydraulic conductivity occurred in silt deposits with a value of 1×10^{-4} cm/s. Hydraulic conductivity was not measured in the Bedrock Confining Unit.
- Groundwater within the Uppermost Aquifer at the West Ash Pond System meets the definition of a Class I, Potable Resource Groundwater.
- The current Illinois EPA-approved groundwater monitoring program consists of collecting samples from 3 background wells (32, 33, 34) and 9 downgradient wells (21 through 27, 30, 31). Additional groundwater monitoring was initiated at these locations for an expanded list of parameters for four quarters (June 2013 through March 2014) to assess compliance with the IAC 35 Part 620 Section 410 Groundwater Quality Standards for Class I: Potable Resource Groundwater. The results of the groundwater monitoring program to-date indicate the following:
  - Parameters observed in groundwater that are derived from CCRs and exceeded Class I standards were boron and sulfate. Exceedances of Class I standards for boron and sulfate occur in monitoring wells

located immediately adjacent to the ash ponds and one downgradient well (27); these wells also exhibit decreasing boron and sulfate concentrations with time. Monitoring wells located further from the ash ponds, specifically wells 25, 26, 30, and 31 to the south, no longer exceed the Class I standard for boron and have not exceeded a standard since 1996. Based on these observations, the total mass-loading of coal-ash leachate constituents on the groundwater system continues to decline.

  - Arsenic and selenium detected in downgradient wells may be related to CCRs, but selenium was only detected on one occasion at one well located adjacent to the impoundments. Observed geochemical indicators and an arsenic exceedance in a background monitoring well suggest that arsenic may be naturally-occurring.
  - Parameters observed in groundwater that exceeded Class I standards but are not related to CCRs at the West Ash Pond System were iron, lead, manganese, and nitrate.
  - Other inorganic parameters detected occur at concentrations below their respective Class I groundwater standards: TDS, chloride, fluoride, cyanide, barium, nickel, vanadium, and zinc.
  - Antimony, beryllium, cadmium, chromium, cobalt, copper, mercury, silver, and thallium were not detected above their MDLs in any groundwater samples.
  - Organic constituents tested included volatile organic compounds, polychlorinated biphenyls, semi-volatile organic compounds, chlorinated pesticides, chlorinated herbicides and specialized organic parameters endothall, ethylene dibromide and 1,2-dibromo-3-chloropropane. None of organic constituents were detected at concentrations higher than their respective Class I standard.

- An assessment of potable and non-potable water wells for a 2,500-foot radius around the entire Hennepin Power Station property boundary demonstrated that there is no potential for groundwater impact to existing off-site wells from the West Ash Pond System or Hennepin Power Station.
- An evaluation was completed to determine potential CCR groundwater impacts on the Illinois River. The evaluation determined that the primary CCR indicator parameters for the West Ash Pond System, boron and sulfate, would have negligible impacts to the Illinois River.

SYSTEM or SERIES	HYDROGEOLOGIC UNITS	GRAPHIC LOG	ROCK TYPE	WATER-YIELDING CHARACTERISTICS
PLEISTOCENE	Drift (0–300 feet)		Unconsolidated glacial deposits, loess and alluvium (drift).	Water yields variable, largest from thick basal sand and gravel deposits (Sankoty Sand) in bedrock valleys.
PENNSYLVANIAN	(280–475 feet)		Mainly shale with thin sandstone, limestone, and coal beds.	Generally unfavorable as an aquifer. Locally, domestic and farm supplies obtained from thin limestone and sandstone beds. Casing usually required.
SILURIAN	Niagaran-Alexandrian (410–505 feet)		Dolomite; argillaceous near base, lower part cherty.	Generally yields poor quality water.
ORDOVICIAN	Maquoketa (155–240 feet)		Green to blue shale with limestone and dolomite beds.	Not water yielding at most places. Casing required.
	Galena-Platteville (320–380 feet)		Dolomite, with shaly zone near the middle; some limestone in the lower part.	Not important as an aquifer, Creviced dolomite probably yields some water. Water quality good.
	Glenwood-St. Peter (115–135 feet)		Sandstone, white, clean.	Dependable source of groundwater. Water quality good.
	Shakopee (130–150 feet)		Dolomite, with some shale and sandstone.	Not important as aquifer.
	New Richmond (165 feet ±)		Sandstone, with some dolomite.	May yield some water.
	Oneota (215 feet ±)		Dolomite, with some sandstone beds.	Not important as aquifer.

ALLUVIUM. DEPOSITS OF MODERN RIVERS AND STREAMS IN FLOODPLAINS. LARGELY CLAYEY SILT AND SANDY SILT WITH LENSES OF SAND AND GRAVEL. GENERALLY LESS THAN 20 FEET THICK. IN THE ILLINOIS VALLEY WEST OF STARVED ROCK, IT IS AS MUCH AS 40 FEET THICK AND IT OVERLIES THICK DEPOSITS OF SAND AND GRAVEL OF THE HENRY FORMATION. IN THE ILLINOIS VALLEY EAST OF STARVED ROCK, IT IS LARGELY SAND AND GRAVEL 15–30 FEET THICK UNDER THIN SILT AND IT OVERLIES BEDROCK FORMATIONS. (CAHOKIA ALLUVIUM)

TILL. MOSTLY UNSORTED CALCAREOUS PEBBLY SILTY CLAY DEPOSITED BY GLACIERS. CONTAINS SCATTERED COBBLES AND BOULDERS AND, IN PLACES, LENSES OF SAND AND GRAVEL. GENERALLY 25–50 FEET THICK BUT AS MUCH AS 300 FEET THICK IN DEEP VALLEYS IN THE BEDROCK SURFACE, WHERE IT INCLUDES THE GLASFORD AND BANNER FORMATIONS. THE TILL HAS A THIN COVER OF CLAYEY SILT (RICHLAND LOESS), THE THICKNESS OF WHICH IS SHOWN ON THE SMALL INSET MAP. (WEDRON FORMATION)

HIGH–LEVEL TERRACES UNDERLAIN BY GLACIAL OUTWASH. SURFACES ARE 75–100 FEET ABOVE THE ILLINOIS RIVER. MOSTLY FINE GRAVEL AND PEBBLY SAND, BUT THE UPPER PART IS LOCALLY COARSER AND BOULDERY, AS ALONG ALLFORKS CREEK, NORTHEAST OF HENNEPIN. GENERALLY 10–30 FEET THICK IN THE TRIBUTARY VALLEYS, BUT AS MUCH AS 150–200 FEET THICK IN THE LARGE TERRACE ON WHICH HENNEPIN IS LOCATED. (HENRY FORMATION)

LOW–LEVEL TERRACES UNDERLAIN BY DEPOSITS OF THE CHICAGO OUTLET RIVER. SURFACES ARE COMMONLY 20–40 FEET ABOVE THE ILLINOIS RIVER. MOSTLY FINE TO COARSE GRAVEL, COARSER AND MORE UNIFORMLY SORTED THAN THE HIGH–TERRACE DEPOSITS. LARGELY 20–50 FEET THICK ALONG THE ILLINOIS VALLEY AND 10–20 FEET ALONG TRIBUTARIES. (HENRY FORMATION)

REFERENCES

1. SOURCE DRAWING DERIVED FROM CEC, INC.; PROJECT NUMBER 164-478, DRAWING NUMBER C200, DATED 3/27/17.
2. TOP OF EXISTING GRADE BASED ON DATA PROVIDED BY WEAVER CONSULTING GROUP SURVEY (2015) AS PRESENTED BY CEC INC.
3. GEOLOGIC INTERPRETATIONS ARE BASED ON BORING LOGS PERFORMED BY CEC INC., AECOM, SCIENCE AND TECHNOLOGY MANAGEMENT INC., JOHN MATHES & ASSOCIATES INC., AND NATURAL RESOURCE TECHNOLOGY INC.

LEGEND

- MISCELLANEOUS BERM SOIL FILL
- CCR/ASH
- SILTS AND CLAYS (ALLUVIAL)
- SANDS WITH FINES (ALLUVIAL)
- SAND AND GRAVEL (GLACIAL OUTWASH)
- INTERPRETED NATURAL GROUND SURFACE OUTSIDE OF ASH POND

GEOLOGIC CONDITIONS

1. THE TEST BORING INFORMATION PRESENTED HEREIN DEPICTS SUBSURFACE CONDITIONS AT THE TEST BORING LOCATIONS AND AT THE TIME OF DRILLING. SOIL CONDITIONS AT OTHER LOCATIONS MAY DIFFER.
2. GEOLOGIC CORRELATIONS BETWEEN TEST BORINGS ARE GENERALLY BASED ON STRAIGHT-LINE INTERPOLATION. ACTUAL CONDITIONS BETWEEN TEST BORINGS MAY DIFFER.

Project No. 135-1.31

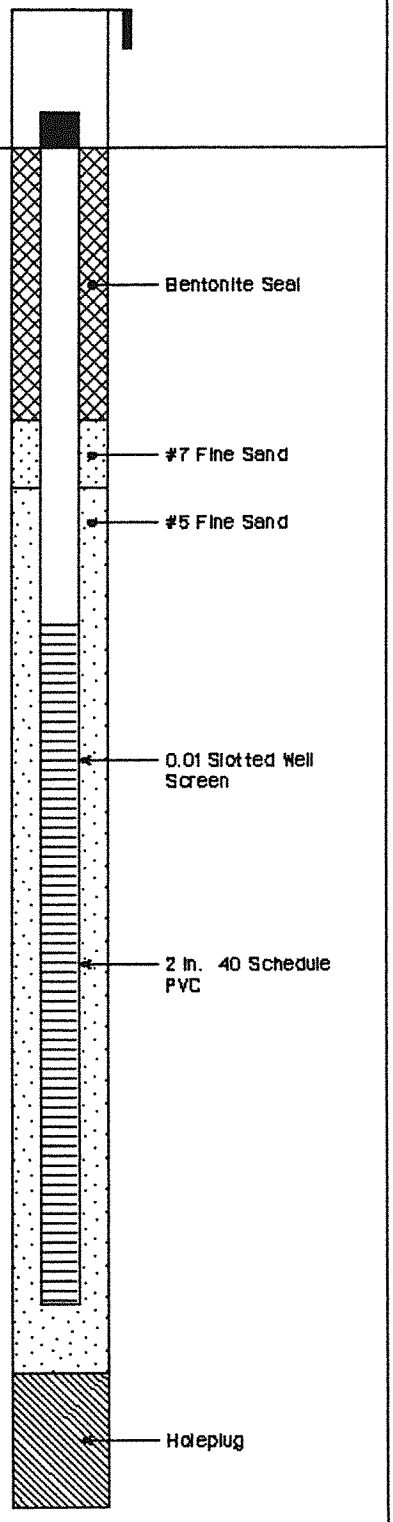
Monitoring Well No. 32

PROJECT Title: Hennepin West Ash Impoundment
DATE: 8-21-96
LOGGED BY: Mueller/Tu
DRILL RIG: Hollow Stem Auger
HOLE DIA.: 7 in.
SAMPLER: Split Spoon
DRILLER: Boart Longyear
FINAL GW: 5.06 ft.
HOLE ELEV.: 451.35 ft. MSL

DESCRIPTION	USCS CLASS	GRAPHIC LOG	DEPTH	SAMPLE
Clay, little organic debris (twigs, wood chips, fine roots), dark brown, low to medium plasticity, moist (alluvium)			0–4	A-1A
Sand, well sorted, subangular to rounded, little silt, some clay, loose red to brown in color. Saturated at approximately 4 to 4.5ft.			4–9	A-1B
Sand and gravel, medium-grained, well-rounded, well sorted quartz and sand, fine to coarse-grained, subangular to subrounded quartz and calcareous gravel. Redish-brown in color (alluvium). Wet.			9–11	A-1C
			11–20	A-1D



STMI
2511 N. 124th St. Suite 205
Brookfield, Wisconsin 53005-8208

Notes:
Dicontinuously sampled every 5 feet. Sample numbers refer to saved samples

Project No.
135-1.31

REFERENCE

1. DATA FROM GROUNDWATER SURFACE PROVIDED BY NRT, DATED SEPTEMBER 2015.

LEGEND

- AVERAGE NORTH/NORTHWEST OF UNIT HIGH GROUNDWATER ELEVATIONS FROM 1996–2015 (451.5 FT. MSL)
- TOP OF EXISTING GRADE (2015 WEAVER CONSULTING GROUP SURVEY)
- INTERPRETED NATURAL GROUND SURFACE (450) OUTSIDE OF ASH POND
- P-4 / 451.1 — SOIL BORING / GROUND SURFACE ELEVATION
- MISCELLANEOUS BERM SOIL FILL
- CCR/ASH
- NATIVE SOIL

GEOLOGIC CONDITIONS

1. THE TEST BORING INFORMATION PRESENTED HEREIN DEPICTS SUBSURFACE CONDITIONS AT THE TEST BORING LOCATIONS AND AT THE TIME OF DRILLING. SOIL CONDITIONS AT OTHER LOCATIONS MAY DIFFER.
2. GEOLOGIC CORRELATIONS BETWEEN TEST BORINGS ARE GENERALLY BASED ON STRAIGHT–LINE INTERPOLATION. ACTUAL CONDITIONS BETWEEN TEST BORINGS MAY DIFFER.

RISING TAILWATER LEVEL

TERRACON PROJECT NO.: **MR155233** **12/21/2015**
PROJECT NAME: **DYNERGY - HENNEPIN SITE**
CLIENT: **AECOM**
LOCATION : **HENNEPIN, IL**

SUMMARY OF TEST RESULTS

BORING NO. HEN-B010

SAMPLE NO. S-5

DEPTH: 10.0'-11.5'

CLASSIFICATION VERY DARK GRAY FLY ASH WITH SAND AND GRAVEL

	INITIAL	FINAL
DRY UNIT WEIGHT (pcf)	86.6	93.3
WATER CONTENT (%)	26.5	23.2
DIAMETER (cm)	7.215	6.956
LENGTH (cm)	4.527	4.521

SAMPLE PHOTO

HYDRAULIC GRADIENT (MAXIMUM) 20.83

PERCENT SATURATION 99.5 (Percent saturation calculation is based on final measurements and an estimated specific gravity.)

HYDRAULIC CONDUCTIVITY k (cm/sec) 1.16E-05

Deaired water was used as the liquid permeant.

RE: 30% Design Data Report for Dynegy Hennepin Power Station; West Polishing Pond, West Ash Pond, East Ash Pond and Ash Pond No. 2 CCR Units

Dear Mr. Ballance:

AECOM is pleased to provide this 30% Design Data Package for the West Polishing Pond, West Ash Pond, East Ash Pond and Ash Pond No. 2 Coal Combustion Residuals (CCR) units at Hennepin Power Station (Hennepin, IL). The Data Package includes summary tables, field exploration plan, and laboratory data.

At Hennepin, the geotechnical exploratory program included the following:

- 32 auger borings
- 38 CPT soundings
- 7 standpipe piezometers installed at selected boring locations.

AECOM looks forward to providing continued support to Dynegy and working together on this important program. Please do not hesitate to call the undersigned, if you have any questions or comments on this 30% Design Data Package.

Sincerely,

AECOM

Jeremy M. Thomas, P.E.

Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767

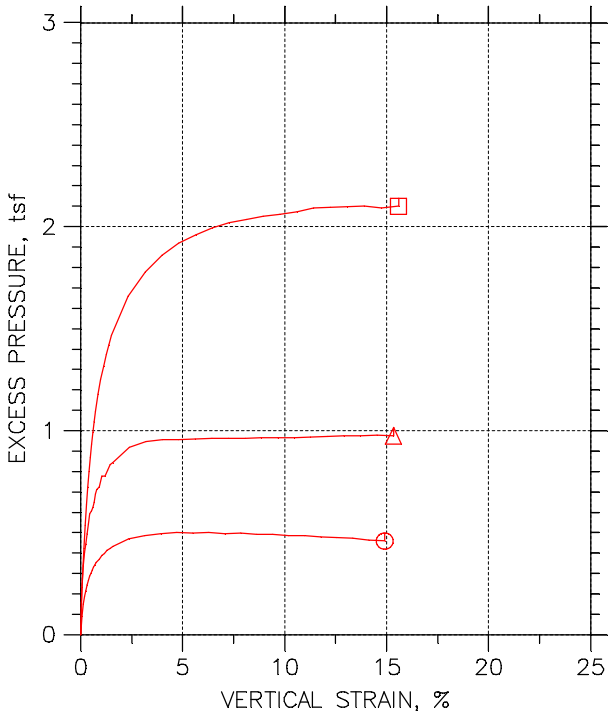
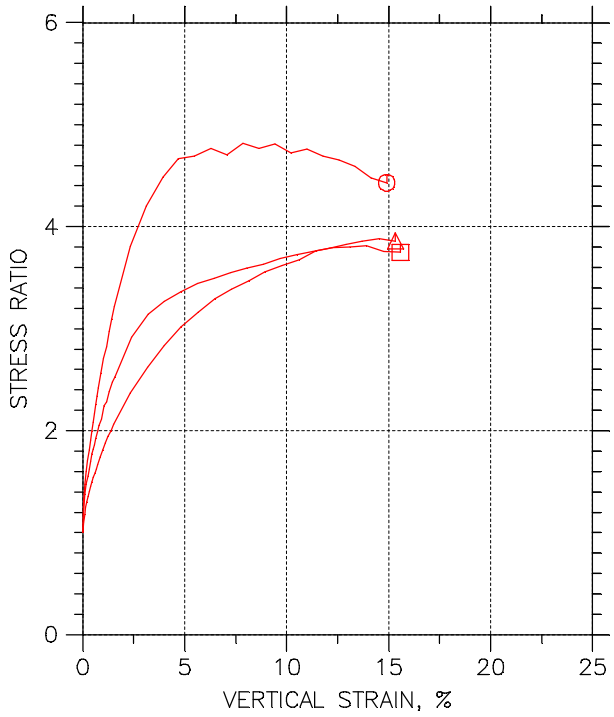
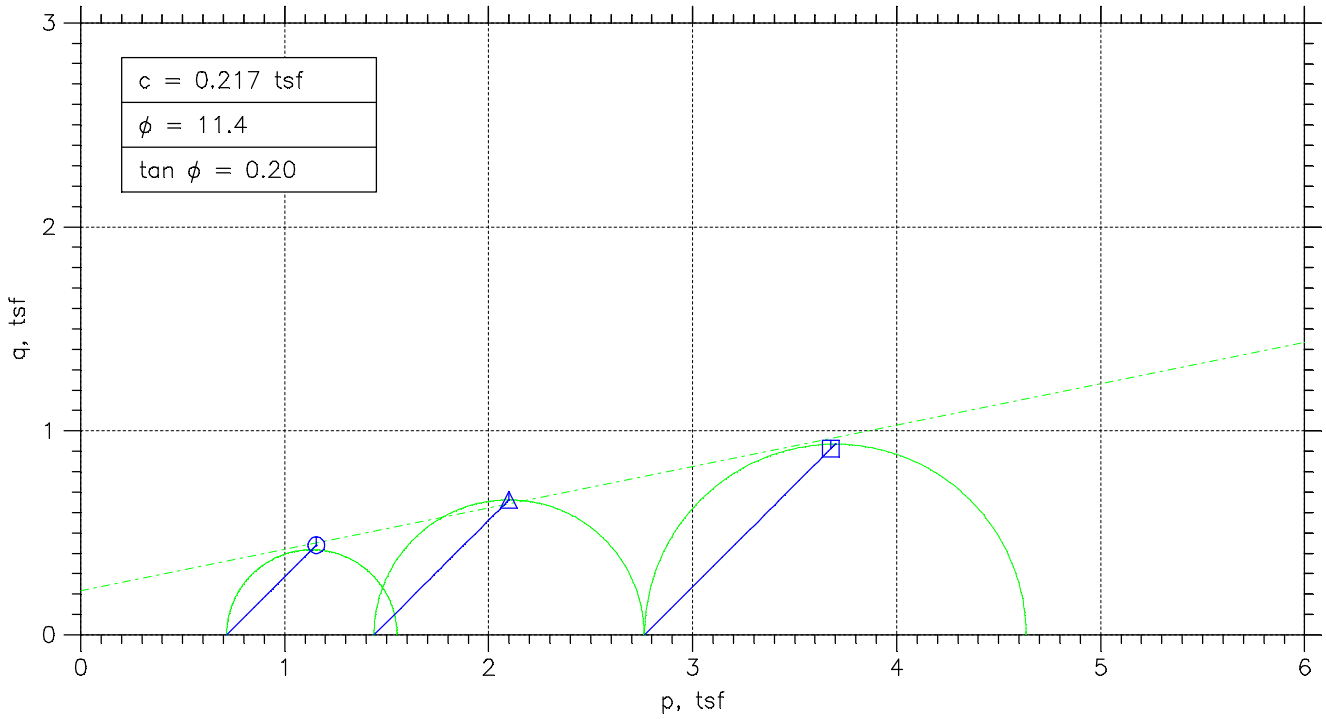
Tue, 22-DEC-2015 10:05:37

CONSOLIDATED-UNDRAINED TRIAXIAL COMPRESSION TEST
ASTM D4767







Project: DYNERGY HENNEPIN	Location: HENNEPIN, IL	Project No.: MR155233
Boring No.: HEN-016 S7	Tested By: BCM	Checked By: WPQ
Sample No.: S-7	Test Date: 12/16/15	Depth: 20.0'-22.0'
Test No.: HEN-016 S7	Sample Type: 3.0" ST	Elevation: -----
Description: VERY DARK GRAY CLAY WITH SAND AND GRAVEL - ORGANICS AND ASH NOTED		
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767		
307		

TRIAXIAL TEST

Project: DYNERGY HENNEPIN
Boring No.: HEN-016 S7
Sample No.: S-7
Test No.: 10.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/16/15
Sample Type: 3.0" ST

Project No.: MR155233
Checked By: WPQ
Depth: 20.0'-22.0'
Elevation: -----

Soil Description: VERY DARK GRAY CLAY WITH SAND AND GRAVEL - ORGANICS AND ASH NOTED
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767

Specimen Height: 5.97 in
Specimen Area: 6.19 in^2
Specimen Volume: 36.94 in^3

Piston Area: 0.00 in^2
Piston Friction: 0.00 lb
Piston Weight: 0.00 lb

Filter Strip Correction: 0.00 tsf
Membrane Correction: 0.00 lb/in
Correction Type: Uniform

Liquid Limit: 38

Plastic Limit: 21

Estimated Specific Gravity: 2.72

TRIAXIAL TEST

Project: DYNERGY HENNEPIN
Boring No.: HEN-016 S7
Sample No.: S-7
Test No.: 40.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/16/15
Sample Type: 3.0" ST

Project No.: MR155233
Checked By: WPQ
Depth: 20.0'-22.0'
Elevation: ----

Terracon
Consulting Engineers & Scientists

Soil Description: VERY DARK GRAY CLAY WITH SAND AND GRAVEL - ORGANICS AND ASH NOTED
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767.

Specimen Height: 6.04 in
Specimen Area: 6.17 in^2
Specimen Volume: 37.26 in^3

Piston Area: 0.00 in^2
Piston Friction: 0.00 lb
Piston Weight: 0.00 lb

Filter Strip Correction: 0.00 tsf
Membrane Correction: 0.00 lb/in
Correction Type: Uniform

Liquid Limit: 38

Plastic Limit: 21

Estimated Specific Gravity: 2.72

TRIAXIAL TEST

Project: DYNERGY HENNEPIN
Boring No.: HEN-018 S-5
Sample No.: S-5
Test No.: 10.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/16/15
Sample Type: 3" ST

Project No.: MR155233
Checked By: WPQ
Depth: 10.0'-12.0'
Elevation: -----

Terracon Consulting Engineers & Scientists

Soil Description: DARK GRAY TO GRAY FLY ASH WITH SAND AND GRAVEL
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D 4767

Specimen Height: 5.98 in
Specimen Area: 6.44 in^2
Specimen Volume: 38.52 in^3

Piston Area: 0.00 in^2
Piston Friction: 0.00 lb
Piston Weight: 0.00 lb

Filter Strip Correction: 0.00 tsf
Membrane Correction: 0.00 lb/in
Correction Type: Uniform

Liquid Limit: NP

Plastic Limit: NP

Estimated Specific Gravity: 2.30

TRIAXIAL TEST

Project: DYNERGY HENNEPIN
Boring No.: HEN-029 S-3
Sample No.: S-3
Test No.: 10.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/17/15
Sample Type: 3.0" ST

Project No.: MR155233
Checked By: WPQ
Depth: 5.0'-7.0'
Elevation: ----

Terracon
Consulting Engineers & Scientists

Soil Description: BROWN LEAN CLAY WITH SAND AND GRAVEL CL
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767.

Specimen Height: 5.99 in
Specimen Area: 6.12 in^2
Specimen Volume: 36.66 in^3

Piston Area: 0.00 in^2
Piston Friction: 0.00 lb
Piston Weight: 0.00 lb

Filter Strip Correction: 0.00 tsf
Membrane Correction: 0.00 lb/in
Correction Type: Uniform

Liquid Limit: 22

Plastic Limit: 15

Estimated Specific Gravity: 2.72

TRIAXIAL TEST

Project: DYNERGY HENNEPIN
Boring No.: HEN-029 S-3
Sample No.: S-3
Test No.: 20.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/17/15
Sample Type: 3.0" ST

Project No.: MR155233
Checked By: WPQ
Depth: 5.0'-7.0'
Elevation: ----

Terracon
Consulting Engineers & Scientists

Soil Description: BROWN LEAN CLAY WITH SAND AND GRAVEL CL
Remarks: FAILURE CRITERIA = MAXIMUM EFFECTIVE STRESS RATIO TEST PERFORMED AS PER ASTM D4767.

Specimen Height: 6.03 in
Specimen Area: 6.27 in^2
Specimen Volume: 37.81 in^3

Piston Area: 0.00 in^2
Piston Friction: 0.00 lb
Piston Weight: 0.00 lb

Filter Strip Correction: 0.00 tsf
Membrane Correction: 0.00 lb/in
Correction Type: Uniform

Liquid Limit: 22

Plastic Limit: 15

Estimated Specific Gravity: 2.72

DIRECT SHEAR TEST DATA

Project: DYNEGY HENNEPIN
Boring No.: HEN-002 S-10
Sample No.: S-10
Test No.: 60.0 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/29/15
Sample Type: TRIMMED

Project No.: MR155233
Checked By: WPQ
Depth: 35.0'-37.0'
Elevation: ----

Soil Description: GRAY LEAN CLAY CL
Remarks:

DIRECT SHEAR TEST DATA

Terracon Consulting Engineers & Scientists

Project: DYNEGY HENNEPIN
Boring No.: HEN-019 S-7
Sample No.: S-7
Test No.: 80 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/146/15
Sample Type: TRIMMED

Project No.: MR155233
Checked By: WPQ
Depth: 25.0'-27.0'
Elevation: ----

Soil Description: VERY DARK GRAY ORGANIC SILT WITH SAND OL SHELLS NOTED
Remarks: TEST PERFORMED AS PER ASTM D3080.

Step: 1 of 1

DIRECT SHEAR TEST DATA

Project: DYNEGY HENNEPIN
Boring No.: HEN-025 S-6
Sample No.: S-6
Test No.: 40 PSI

Location: HENNEPIN, IL
Tested By: BCM
Test Date: 12/13/15
Sample Type: TRIMMED

Project No.: MR155233
Checked By: WPQ
Depth: 11.5'-13.5'
Elevation: ----

Soil Description: VERY DARK GRAY FLY ASH WITH SAND
Remarks:

Step: 1 of 1

Hydraulic Conductivity Tests
ASTM D 5084

Terracon
Consulting Engineers & Scientists

Laboratory Services Group 750 Corporate Woods Parkway Vernon Hills, Illinois 60061 Phone:(847) 793-0306 Fax:(847) 793-0309

HYDRAULIC CONDUCTIVITY DETERMINATION
ASTM D 5084, METHOD C
RISING TAILWATER LEVEL

TERRACON PROJECT NO.: **MR155233** **12/21/2015**
PROJECT NAME: **DYNERGY - HENNEPIN SITE**
CLIENT: **AECOM**
LOCATION : **HENNEPIN, IL**

SUMMARY OF TEST RESULTS

BORING NO. HEN-B010

SAMPLE NO. S-5

DEPTH: 10.0'-11.5'

CLASSIFICATION VERY DARK GRAY FLY ASH WITH SAND AND GRAVEL

	INITIAL	FINAL
DRY UNIT WEIGHT (pcf)	86.6	93.3
WATER CONTENT (%)	26.5	23.2
DIAMETER (cm)	7.215	6.956
LENGTH (cm)	4.527	4.521

SAMPLE PHOTO

HYDRAULIC GRADIENT (MAXIMUM) 20.83

PERCENT SATURATION 99.5 (Percent saturation calculation is based on final measurements and an estimated specific gravity.)

HYDRAULIC CONDUCTIVITY k (cm/sec) 1.16E-05

Deaired water was used as the liquid permeant.

SUMMARY OF TEST RESULTS

BORING NO. HEN-B023

SAMPLE NO. S-9

DEPTH: 27.0'-29.0'

CLASSIFICATION VERY DARK GRAY FLY ASH WITH SAND AND GRAVEL

	INITIAL	FINAL
DRY UNIT WEIGHT (pcf)	81.8	83.2
WATER CONTENT (%)	28.3	31.5
DIAMETER (cm)	7.154	7.063
LENGTH (cm)	5.432	5.479

SAMPLE PHOTO

HYDRAULIC GRADIENT (MAXIMUM) 17.36

PERCENT SATURATION 100.4 (Percent saturation calculation is based on final measurements and an estimated specific gravity.)

HYDRAULIC CONDUCTIVITY k (cm/sec) 1.00E-05

Deaired water was used as the liquid permeant.

1 OVERVIEW

This report has been prepared for Dynegy Midwest Generation, Inc. (DMG) by Kelron Environmental and Natural Resource Technology, Inc. (NRT) and is intended to meet well survey procedures in relevant Illinois and federal regulations[1], including the "Right to Know" Potable Water Well Survey procedures of 35 Illinois Administrative Code 1600.210(b)(1) and 1600.210(b)(2). The purpose of this survey is to identify all existing water wells located within 2,500 feet of the property boundary of DMG's Hennepin Power Station (HPS or Facility), located within the Village of Hennepin's northern municipal limits in Putnam County, Illinois. The HPS property boundary (Figure 1) is located in:

- The north half of the southeast quarter and the south half of the northeast quarter of Section 27; and
- The north half of the northwest quarter of the southeast quarter; the north half of the northwest quarter of the southwest quarter; and, the north half of the northeast quarter of the southwest quarter of Section 26.

A non-community wellhead protection area (WHPA) has been designated by the Illinois Environmental Protection Agency (Illinois EPA) and Illinois Department of Public Health (IDPH) south of the East Ash Pond System and property boundary (Figures 1 and 2). A total of 11 water supply wells were identified within the search radius outside of the HPS property boundary using Illinois EPA, Illinois State Geological Survey (ISGS), Illinois State Water Survey (ISWS) information, and a visual survey. Additionally, four water wells owned by DMG are located within the HPS property boundary. Within the search radius, one well (Well #4) is located east of the Facility, one well (Well #3) is located west of the Facility, and nine wells are located south of the Facility (Well numbers 5 through 11, 14, and 15). One well (Well #7) is designated as a non-community water supply well (non-CWS). All these wells are either upgradient or side gradient from the active and out-of-service ash pond systems of the HPS.

[1] Leaking Underground Storage Tank regulations (35 Ill. Adm. Code 732); Leaking Underground Storage Tank regulations (35 Ill. Adm. Code 734); Site Remediation Program (35 Ill. Adm. Code 740.425(b)(2)(D)); RCRA Permit regulations (35 Ill. Adm. Code 703.183(s)(9); 35 Ill. Adm. Code 703.184(a)(3)); and the National Contingency Plan (40 CFR 300.430(d)).

2 WATER WELL DATABASE AND ALTERNATE SEARCH RESULTS

The following databases and sources of information were utilized in order to determine community water source and potable water well locations and construction in the vicinity of the HPS property boundary:

- Illinois State Geological Survey -Water Well Database Query;
- Illinois State Water Survey private well database;
- Illinois EPA web-based Geographic Information System (GIS) files;
- Illinois Department of Public Health;
- Putnam County Health Department; and
- Field observation of wells from visual survey.

2.1 Illinois State Geological Survey (ISGS)

The ISGS website provided an ArcIMS Viewer Map as well as a database query. According to the ISGS ArcIMS Viewer Map, 11 water wells are located within a 2,500-foot radius of the HPS property boundary (Figures 1 and 2). The wells are numbered 1, 2, 4 through 9, 12, and 13 on the map. Each map location number represents one well identification, with the exception of map Well #6, which appears to have two listings for the same well (Table 1). The ISGS database information, including any boring log and well construction information, is provided in Appendix A. Four mapped well numbers occur on the Facility property as follows:

- Well #1, located southwest of the main plant near the front entrance gate; and,
- Wells #2, #12, and #13 located south of the main plant and midway between the East and West Ash Pond Systems.

Well #1 was located incorrectly on the original driller's log and this error has been propagated through the ISGS (and ISWS and IEPA) databases. This well is used for irrigation of the coal pile and is not a potable source.

The depths of the wells in the ISGS database ranged from 64 to 128 feet deep. All wells, where lithology information is provided, obtain water from unconsolidated sand and gravel deposits. The ISGS water well database also contained test borings for DMG's Facility; none of these borings were for potable wells and were not included within the search results presented in this report.

2.2 Illinois State Water Survey (ISWS)

The ISWS database of well records included records for the wells identified in the ISGS database, with the exception of well numbers 4 and 12, for which there were no ISWS records. There were also two ISWS Private Well Database records that did not appear in any other databases: well numbers 3 and 14, both of which are very old wells with only approximate locations and unknown ownership. Wells #3 and #14 are dug wells with recorded construction dates of 1844 and 1922, respectively, and were most likely abandoned decades ago.

A number of well records from the ISWS contained minimal information for mapping; therefore, these wells are not included in this report as sufficient information was provided to determine the wells are not within the 2,500 feet search radius. A copy of the ISWS Private Well database records is included in Appendix B.

2.3 Illinois Environmental Protection Agency (Illinois EPA)

The Illinois EPA Database website provided ArcIMS Viewer Maps (Appendix C). The database provides information on community, non-community, and public water supply wells as defined on the Illinois EPA website:

- Community Water Supply: *a public water supply that serves or is intended to serve at least 15 service connections used by residents or regularly serves at least 25 residents.*
- Non-community Water Supply: *a public water supply that is not a community water supply.*
- Public Water Supply: *all mains, pipes and structures through which water is obtained and distributed to the public, including wells and well structures, intakes and cribs, pumping stations, treatment plants, reservoirs, storage tanks and appurtenances, collectively or severally, actually used or intended for use for the purpose of furnishing water for drinking or general domestic use and which serve at least 15 service connections or which regularly serve at least 25 persons at least 60 days per year. A public water supply is either a community water supply or a non-community water supply.*

Based on the Illinois EPA maps, community water systems (CWS) are not present within a 2,500 feet radius of the HPS property boundary. The nearest CWS wells and system details, included in Appendix C, are:

- Village of Depue (Facility Number 0110300) located approximately 1.5 miles north of the Facility;
- Village of Hennepin (Facility Number 1555100) located approximately 3 miles south of the Facility;
- Village of Bureau Junction (Facility Number 0110150) located approximately 3 miles southwest of the Facility; and
- Village of Granville (Facility Number 1550050) located approximately 3.5 miles southeast of the Facility.

According to Illinois EPA records, the HPS property boundary is located greater than 1-mile from the Minimum Setback Zones, Existing or Potential Maximum Setback Zones, and /or Recharge Areas for the CWS systems.

Based on the Illinois EPA maps, there is one non-community supply (non-CWS) well, 6 industrial / commercial wells, and 2 farm/domestic water wells located within the 2,500 feet radius of the HPS property boundary (Figures 1 and 2). All wells identified on Illinois EPA maps were also identified in ISGS and/or ISWS records. The non-CWS water supply system (Appendix C) is identified as the Exolon ESK System #0117408, which consists of one well (Map Well #7). The WHPA for this system lies within the 2,500-foot search radius (Figures 1 and 2) but south of the Hennepin Power Station's property boundary.

A wellhead protection area (WHPA) is the surface and subsurface area surrounding a water well or well field supplying a CWS or non-CWS water system through which contaminants from a source are theoretically likely to move and reach the water well or well field. All CWS and non-CWS systems utilizing groundwater in Illinois have a 1,000-foot wellhead / source water protection radius, also referred to as a Phase I WHPA.

2.4 Illinois Department of Public Health (IDPH)

The IDPH was contacted for confirmation information on the Exolon non-CWS system. J. Scott Bell with the IDPH confirmed the system is the only non-CWS within the search radius. Mr. Bell also stated the system is now identified as the Washington Mills non-CWS (Appendix D).

2.5 Putnam County Health Department

Personnel from the Bureau-Putnam County Health Department were not able to confirm or provide additional data on the non-CWS well system (Appendix D).

2.6 Visual Survey

A visual survey, also referred to as a windshield survey, was conducted on April 14, 2009 to verify some well locations listed in the databases and also to locate wells not identified by ISGS, ISWS, Illinois EPA or DMG sources. Three wells were field identified (Table 1; Figures 1 and 2) that did not have corresponding well logs in any of the database sources: Well #10, located on property owned by Tri-Con Materials; and Wells #11 and #15, located on property that appears to be owned by Advanced Asphalt. All three of these wells are industrial-commercial wells with unknown operational status as to whether they are active or inactive.

3 CONCLUSIONS

According to database records of the ISGS, ISWS, and Illinois EPA, there are eight water wells (assumed to be potable) owned by private residences or companies within a 2,500 feet radius of the HPS property boundary and four water wells owned by DMG are located on the HPS property (Table 1). Three additional undocumented industrial-commercial wells were identified at locations south and southeast of the Facility during a visual (windshield) survey. A total of 15 water wells have been identified both on DMG's HPS property and within a 2,500-foot radius of the Facility property boundary.

In addition to the above sources of water well information provided by State agencies, Kelron obtained information from DMG personnel and the IDPH. Personnel with both these entities had no knowledge or information of any additional wells within a 2,500 feet radius of the HPS property boundary beyond those identified within the State databases.

The results of the water well survey are provided in Appendices A through D for each of the sources of information contacted. Based on all of the well information acquired from the listed sources, water supply wells within at least 2,500 feet of the HPS property boundary were placed on a topographic map (Figure 1) and aerial photograph (Figure 2) and shown in relation to the HPS property boundary. The current status of some of these wells (i.e., operational, abandoned, or sealed) is not known.

Source Water Assessment Summary

0117408 - EXOLON ESK

Last Updated on 2/3/2006

Source of Groundwater
The Exolon Company water supply system consists of one well. The well draws its water supply from an unconfined aquifer, which consists of sand.

Source Water Quality
The well at the Exolon Company is sampled for bacteria, nitrate/nitrites and lead and copper. In addition the Exolon Company is also required to sample for inorganic compounds (IOC), volatile compounds (VOC), and synthetic compounds (SOC).

On review of the geological composition, land-use practices, and well construction it was found that the well is susceptible to VOC, SOC, IOC, nitrate/nitrites, and bacteria.

Construction/Treatment
The Exolon Company has a 12-inch drilled well with steel casing. The well has an estimated depth of 130 feet. The well has a turbine pump and a 1,000 pressurized storage tank. The well receives no treatment.

Finished Water Quality
A review of the Exolon Company water supply at this time shows that the system is in compliance with the groundwater quality standards established under 35 Illinois Administrative Code Part 620.

Potential Sources of Contamination
The following sites are listed as potential sources of contamination due to the nature of their activity and their geographic proximity (within a 1,000 foot buffer) to the source water protection area.

See Table on Topographic Map Coverage(Second Map)

Susceptibility to Contamination
The Illinois Department of Public Health has determined that the Exolon Company water supply has a high susceptibility to contamination. This determination is based on a number of criteria including: available geological data, land-use practices, and well depth.

Illinois Environmental Protection Agency

Source Water Assessment Program

FACT SHEET

DE PUE

BUREAU COUNTY

Prepared in cooperation with the U.S. Geological Survey.

Information and data used in the preparation of this Fact Sheet are provided by the Illinois EPA and are subject to revision.

IMPORTANCE OF SOURCE WATER:

The Village of DePue (Facility Number 0110300) has two public water supply wells. Wells #2 and #3 (IEPA #11336 and #11337) produce 176,300 gallons per day on average to an estimated population of 1729 through 710 service connections.

WATER SUPPLIES THAT OBTAIN SOURCE WATER FROM THIS FACILITY:

As of January 2001, no other facilities purchase water from this community water supply.

SOURCE OF WATER SUPPLY:

Wells #2 and #3 are located behind the waterworks on 2nd Street. Wells #2 and #3 pump 220 and 250 gallons per minute, respectively, and have a production capacity of 288,000 gallons per day. Wells #2 and #3 are 1487 and 1490 feet deep, respectively, and utilize a deep bedrock aquifer. The bedrock is overlain by permeable river deposits and impermeable bedrock. The aquifer utilized is considered confined by the Illinois EPA, therefore is not considered geologically sensitive.

WELL DATA FOR THIS FACILITY:

Well ID	Well Description	Status	Depth (Feet)	Min Setback (Feet)	Aquifer Description
11336	WELL 2	A	1487	200	DEEP BEDROCK
11337	WELL 3	A	1490	200	DEEP BEDROCK

SOURCE WATER QUALITY:

The public water supply wells at DePue were sampled as part of a Statewide Groundwater Monitoring Network on March 12, 1987. The well samples were analyzed for volatile organic compounds (VOC) and inorganic chemicals (IOC). The analyses detected no quantifiable levels of VOC in either well. The inorganic analyses performed found the water from both wells to meet all groundwater quality standards established in 35 Illinois Administrative Code Part 620.410.

FINISHED WATER QUALITY:

Finished water quality data tables of monitored parameters, contaminants detected, health advisory information, drinking water standards or maximum contaminant levels are available at http//www.epa.gov/ogwdw. Similar information is also available in the Consumer Confidence Report supplied by the water supply to its customers. A review of this information does not indicate levels of organic or inorganic compounds which exceed the drinking water quality standards. Radium and Alpha emitters were detected in radionuclide analyses done in 1999. Alpha emitters were detect at a level of 15 pCi/l and combined radium was detected at a level of 6.9 pCi/l, the maximum

contaminant levels (MCL) are 15 and 5 pCi/l respectively.

POTENTIAL SOURCES OF CONTAMINATION:

The site labeled on the Wellhead Protection Planning Map and described in the following table is considered a "potential" source of contamination. (Maps and tables are not available in the Visually Impaired version. However, the information presented in these maps and tables is summarized within the following text sections of this fact sheet.) The Illinois EPA performed a detailed well Site Survey in 1989 to identify potential sources of contamination to the village's wells. These sources are identified based on the nature of its activity, the availability of data in the electronic data bases, and its geographical proximity to the source water protection area. In addition, the Illinois EPA made use of its information from the its leaking underground storage tank database (http://epadata.epa.state.il.us/land/ust/search.asp) and site remediation program database (http://epadata.epa.state.il.us/land/srp/search.asp) to further assess potential sources of contamination to the community's source water. These databases include information from the Illinois EPA Division of Land Pollution Control (LPC) and the Illinois Emergency Management Agency (IEMA). The following list of facilities contained within these databases. As a result of multiple possible contamination sources, individual sites may be listed on the table more than once in relation to the wells.

IEMA #900361 - LPC #0110300003 - Mobil Chemical Company, Depot & Marquette Streets., Depue 61322

SITE DATA FOR THIS FACILITY:

Well ID	Map Code	Site Name	Site Description	Distance (Feet)
11336	02556	CASEY'S GENERAL STORE	BELOW GROUND STORAGE (PET	975
11337	02556	CASEY'S GENERAL STORE	BELOW GROUND STORAGE (PET	975

OTHER IDENTIFIED POTENTIAL SOURCES:

For this community water supply, no additional potential sources of contamination have been identified beyond those in Illinois EPA databases.

SUSCEPTIBILITY TO CONTAMINATION:

Based on information obtained in a Well Site Survey published in 1989 by the Illinois EPA, one "potential" source is located within 1,000 feet of the wells.

The Illinois EPA has determined that the Depue Community Water Supply's source water is not suspectibile to contamination. This determination is based on a number of including: monitoring conducted at the wells; monitoring conducted at the entry point to the distribution system; available hydrogeologic data on the wells; and land use proximite to the wells.

Furthermore, in anticipation of the U.S. EPA's proposed Ground Water Rule, the Illinois EPA has determined that the Depue Community Water Supply is not vulneraible to viral contamination. This determination is based upon the evaluation of the following criteria during the Vulnerability Waiver Process: the community's wells are properly constructed with sound integrity and proper siting conditions; a hydrogeologic barrier exists which should prevent pathogen movement; all potential routes and sanitary defects have been mitigated such that the source water is adequately protected; monitoring data did not indicate a history of disease outbreak; and the sanitary survey of the water supply did not indicate a viral contamination threat. Because the community's wells are constructed in a confined aquifer, which should prevent the movement of pathogens into the wells, well hydraulics was not considered to be a significant factor in the susceptibility determination.

SOURCE WATER PROTECTION EFFORTS:

The Ilinois Environmental Protection Act provides minimum protection zones of 200 feet for your wells. These minimum protection zones are regulated by the Illinois EPA. To further reduce the risk to source water, the water supply has implemented a wellhead protection program which includes the proper abandonment of potential routes of groundwater contamination and correction of sanitary defects at the water treatment facility. This effort resulted in the community water supply receiving a special exception permit from the Illinois EPA which allows a reduction in monitoring. The outcome of this monitoring reduction has saved the community considerable laboratory analysis costs.

To further minimize the risk to the community's groundwater supply, the Illinois EPA recommends that three additional activities be assessed. First, the facility may wish to enact a "maximum setback zone" ordinance. These ordinances are authorized by the Illinois Environmental Protection Act and allow county and municipal officials the opportunity to provide additional protection up to a fixed distance, normally 1,000 feet from their wells. Second, the water supply staff may wish to revisit their contingency planning documents. Contingency planning documents are a primary means to ensure that, through emergency preparedness, a community will minimize their risk of being without safe and adequate water. Finally, the water supply staff is encouraged to review their cross connection control program to ensure that it remains current and viable. Cross connections to either the water treatment plant (for example, at bulk water loading stations) or in the distribution system may negate all source water protection initatives provided by the community.

Illinois Environmental Protection Agency

Source Water Assessment Program

FACT SHEET

HENNEPIN PWD

PUTNAM COUNTY

Prepared in cooperation with the U.S. Geological Survey.

Information and data used in the preparation of this Fact Sheet are provided by the Illinois EPA and are subject to revision.

IMPORTANCE OF SOURCE WATER:

The Village of Hennepin (Facility Number 1555100) obtains its water from three active community water supply wells. Wells #3, #4, and #5 (Illinois EPA #11602, 11603, and 11604, respectively) supply an average of 149,600 gallons per day (gpd) to 312 services or a population of 750.

WATER SUPPLIES THAT OBTAIN SOURCE WATER FROM THIS FACILITY:

No connected water supplies existed at the time this Source Water Assessment fact sheet was completed.

SOURCE OF WATER SUPPLY:

Wells #3 and #4 are located at the central and southern end of Hennepin, respectively, and well #5 is located north of Hennepin. They produce 250, 400, and 650 gallons per minute (gpm), respectively and are operated for a combined maximum output of roughly 341,900 gpd. Wells #3, #4, and #5 are 100, 107, and 135 feet in depth, respectively. All three wells obtain their source water from a shallow, permeable sand and gravel aquifer overlain by materials of variable permeability. Permeability is a measure of the capability of a soil or sediment to transmit fluids. The Illinois EPA considers these wells to be geologically sensitive.

WELL DATA FOR THIS FACILITY:

Well ID	Well Description	Status	Depth (Feet)	Min Setback (Feet)	Aquifer Description
11602	WELL 3	A	100	400	Sand & Gravel
11603	WELL 4	A	107	400	Sand & Gravel
11604	WELL 5	A	135	400	Sand & Gravel

SOURCE WATER QUALITY:

Hennepin's wells have been sampled since January 20, 1981 for inorganic chemicals (IOC), volatile organic compounds (VOC), and synthetic organic compounds (SOC) as part of a Statewide Groundwater Monitoring Program. The VOC and SOC analyses did not detect quantifiable levels of any organic compounds. IOC analyses indicate that concentrations of these chemicals are consistent with other sand and gravel aquifers of similar character in Illinois. It is important to note that the IOC results were below the groundwater quality standards established under 35 Illinois Administrative Code Part 620.410, with the exception of manganese concentrations. Manganese concentrations range from 15 to 339 parts per billion (ppb). The groundwater quality standard for manganese, as established under Part 620.410, is 150 ppb. However, the Illinois EPA considers the elevated level of manganese to be the result of natural mineralization of the aquifer. Hence, the level of manganese is not considered a violation due to the stipulation in Part 620.410 that no violation occurs as a result of a natural occurrence of an IOC.

FINISHED WATER QUALITY:

As referenced in the Source Water Quality Section of this report, Hennepin has mineralized groundwater. Sampling performed after treatment indicates that levels of manganese in the source water have been reduced to below the drinking water standards. Further information on finished water quality data tables of monitored parameters, contaminants detected, health advisory information, drinking water standards and maximum contaminant levels are available at http://www.epa.gov/ogwdw/. Similar information is also available in the Consumer Confidence Report supplied by the Village of Hennepin to their customers.

POTENTIAL SOURCES OF CONTAMINATION:

The sites labeled on the Wellhead Protection Planning Map and described in the following tables are considered "potential" sources of contamination. (Maps and tables are not available in the Visually Impaired Accessible version. However, the information presented in the maps and tables is summarized within the following text sections of this fact sheet.) These sites are predominantly identified through the Illinois EPA's Well Site Survey program based on the nature of their activity, the availability of data in electronic databases, and their geographic proximity to the source water protection area. In addition, the Illinois EPA made use of the information from its leaking underground storage tank database (http://epadata.epa.state.il.us/land/ust/search.asp) and site remediation program database (http://epadata.epa.state.il.us/land/srp/search.asp) to further assess potential sources of contamination to the village's source water. These databases include information from the Illinois EPA Division of Land Pollution Control (LPC) and the Illinois Emergency Management Agency (IEMA). The following is a list of facilities contained within these databases. As a result of multiple possible contamination sources, individual sites may be listed in the table more than once in relation to a well.

11604	22477	LTV STEEL WWTP	WATER TREATMENT PLANT	1600

OTHER IDENTIFIED POTENTIAL SOURCES:

For this community water supply, no additional potential sources of contamination have been identified beyond those in Illinois EPA databases.

SUSCEPTIBILITY TO CONTAMINATION:

To determine Hennepin's susceptibility to groundwater contamination, the Illinois Rural Water Association conducted a well site survey in October, 2002. Based on the information obtained in this document, there are 13

potential sources of groundwater contamination that could pose a hazard to groundwater utilized by Hennepin's community water supply. These include 1 chemical handling facility, 1 manufacturing process, 1 boat yard, 1 sales store, 2 onsite sludge disposals, 2 injection wells, 2 water treatment plants, and 3 above ground fuel storage tanks. In addition, information provided by the Leaking Underground Storage Tank and Remedial Project Management Sections of the Illinois EPA indicated sites with on-going remediation that might be of concern.

According to the Hennepin PWD facility, LTV Steel Co. and the associated injection well and water treatment plant have been sold to the International Steel Group. However, the sludge disposal associated with this site is no longer active.

Based upon this information, the Illinois EPA has determined that the Hennepin Community Water Supply's source water is susceptible to contamination. As such, the Illinois EPA has provided 5-year recharge area calculations for the wells. The land use within the recharge areas of the wells was analyzed as part of this susceptibility determination. This land use includes residential, commercial and agricultural properties.

SOURCE WATER PROTECTION EFFORTS:

The Illinois Environmental Protection Act provides minimum protection zones of 400 feet for Hennepin's wells. These minimum protection zones are regulated by the Illinois EPA. To further reduce the risk to the source water, a maximum protection zone may be established, which is authorized by the Illinois Environmental Protection Act and allows county and municipal officials the opportunity to provide additional potential source prohibitions up to 1,000 feet from their wells.

To further minimize the risk to the village's groundwater supply, the Illinois EPA recommends the following additional activities be considered. First, the water supply staff may wish to conduct contingency planning. Contingency planning documents are a primary means to ensure that, through emergency preparedness, a community will minimize their risk of being without safe or adequate water. Second, the water supply staff is encouraged to conduct a biennial cross connection survey of the distribution system as outlined in the cross connection control ordinance [Section 18 of the Environmental Protection Act 415 ILCS 5/1 et seq. (Act); 35 Illinois Act Code, Sections 607.104d, 653.801c] and to review their cross connection control ordinance to ensure that it remains current and viable. Cross connections to either the water treatment plant (for example, at bulk water loading stations) or in the distribution system may negate all source water protection initiatives. Finally, the Illinois EPA recommends that the village investigate additional source water protection management options to address the land use activities within the wells' recharge area. Specifically, these management options should address potential impacts from non-point sources related to agricultural land uses.

To further reduce the risk to source water, Hennepin may wish to implement a wellhead protection program, which includes the proper abandonment of potential routes of groundwater contamination within the recharge area, management of potential sources of contamination and correction of any sanitary defects that might be present at the water treatment facility. This effort may result in the community water supply receiving a special exception permit from the Illinois EPA, which allows a reduction in monitoring and laboratory analysis costs.

Illinois Environmental Protection Agency

Source Water Assessment Program

FACT SHEET

BUREAU JUNCTION

BUREAU COUNTY

Prepared in cooperation with the U.S. Geological Survey.

Information and data used in the preparation of this Fact Sheet are provided by the Illinois EPA and are subject to revision.

IMPORTANCE OF SOURCE WATER:

The Village of Bureau Junction (Facility Number 0110150) has two public water supply wells. Wells #4 (Illinois EPA #11327) and #5 (Illinois EPA #00729) produce 32,088 gallons per day on average to an estimated population of 340 through 131 service connections.

WATER SUPPLIES THAT OBTAIN SOURCE WATER FROM THIS FACILITY:

No connected water supplies existed at the time this Source Water Assessment fact sheet was completed.

SOURCE OF WATER SUPPLY:

Well #4 is located on Kansas Street between Miller and North Streets. Well #5 is located 300 feet northeast of Well #4. The water from both wells is blended and treated before distribution. Wells #4 and #5 pump 50 and 190 gallons per minute, respectively and the facility has a production capacity of 345,600 gallons per day. Well #4 is 334 feet deep and utilizes a shallow bedrock aquifer and Well #5 is 1,545 feet deep and utilizes a deep bedrock aquifer which are overlain by permeable alluvial deposits and bedrock formations of variable permeability. Permeability is the ability of a soil or sediment to transmit fluids. Permeability is a measure of the ability of a soil or sediment to transmit fluids. Both aquifers utilized are considered confined by the Illinois EPA, therefore are not considered geologically sensitive.

WELL DATA FOR THIS FACILITY:

Well ID	Well Description	Status	Depth (Feet)	Min Setback (Feet)	Aquifer Description
00729	WELL 5	A	1545	200	Cambrian/Ordovician
11326	WELL 2	B	305	400	Devonian/Silurian
11327	WELL 4	A	334	200	Devonian/Silurian

SOURCE WATER QUALITY:

The Well #4 at Bureau Junction has been sampled regularly as part of a Statewide Ambient Groundwater Monitoring Program since March 1, 1994. Well #5 was sampled in 1997. The samples were analyzed for volatile organic compounds (VOC) and inorganic chemicals (IOC). Well #4 has been sampled for synthetic organic chemical and pesticides (SOC). The VOC analyses detected no contaminants. The IOC analyses have indicated a elevated level of chlorides, which is naturally occurring. The IOC results show levels up to 796 part per billion (ppb) in Well #4, and 201 in Well #5, which is above the groundwater standard of 200 ppb. At this time there is no drinking water standard for chlorides established in 35 Illinois Administrative Code Part 620.410. The Illinois EPA considers these chlorides concentrations the result of natural mineralization in the aquifer.

FINISHED WATER QUALITY:

Further information on finished water quality, including data tables of monitored parameters, contaminants detected, health advisory information, drinking water standards and maximum contaminant levels is available at http//www.epa.gov/ogwdw. Similar information is also available in the Consumer Confidence Report supplied by the water supply to its customers. A review of this information does not indicate levels of organic compounds or inorganic chemicals which exceed the drinking water quality standards. Radium were detected in radio nuclide analyses done in 1999. Alpha emitters were detected at a levels ranging from 20 to 23 picoCuries per liter (pCi/l), the maximum contaminant levels (MCL) for combined Alpha emitters is 15 pCi/l. Combined radium was detected at a levels ranging from 4.7 to 8.8 picoCuries per liter (pCi/l), the maximum contaminant levels (MCL) for combined Radium is 5 pCi/l.

POTENTIAL SOURCES OF CONTAMINATION:

The sites labeled on the Wellhead Protection Planning Map and described in the following tables are considered "potential" sources of contamination. (Maps and tables are not available in the Visually Impaired Accessible version. However, the information presented in the maps and tables is summarized within the following text sections of this fact sheet.) The Illinois EPA performed a detailed Well Site Survey in 1994 to identify potential sources of contamination to the water supply's wells. These sources are identified based on the nature of their activity, the availability of data in electronic databases, and their geographic proximity to the source water protection area. In addition, the Illinois EPA made use of information from its leaking underground storage tank database (http://epadata.epa.state.il.us/land/ust/search.asp) and site remediation program database (http://epadata.epa.state.il.us/land/srp/search.asp) to further assess potential sources of contamination to the water supply's source water. These databases include information from the Illinois EPA Division of Land Pollution Control (LPC) and the Illinois Emergency Management Agency (IEMA). The following is a list of facilities contained within these databases. As a result of multiple possible contamination sources, individual sites may be listed in the table more than once in relation to a well.

IEMA # LPC # Site Name Address City ZIP Code
920807 0118995005 Bureau, Village of 101 East Nebraska St. Bureau 61315

11327	02914	UNKNOWN ABANDONED GAS ST	BELOW GROUND STORAGE (PET	850
11327	02912	BILL'S GAS & GENERAL STORE	BELOW GROUND STORAGE (PET	600

OTHER IDENTIFIED POTENTIAL SOURCES:

For this community water supply, no additional potential sources of contamination have been identified beyond those in Illinois EPA databases.

SUSCEPTIBILITY TO CONTAMINATION:

Based on information obtained in a Well Site Survey published in 1994 by the Illinois EPA, several potential secondary sources are located within 1,000 feet of the wells.

The Illinois EPA has determined that the Bureau Junction Community Water Supply's source water is not susceptible to contamination. This determination is based on a number of criteria including; monitoring conducted at the wells; monitoring conducted at the entry point to the distribution system; and available hydro geologic data on the wells.

SOURCE WATER PROTECTION EFFORTS:

The Illinois Environmental Protection Act provides minimum protection zones of 200 feet for Wells #4 and #5. These minimum protection zones are regulated by the Illinois EPA.

To further minimize the risk to the facility's groundwater supply, the Illinois EPA recommends that three additional activities be assessed. First, the water supply may wish to work with village officials to enact a "maximum setback zone" ordinance. These ordinances are authorized by the Illinois Environmental Protection Act and allow county and municipal officials the opportunity to provide additional protection up to a fixed distance, normally 1,000 feet from their wells. Second, the water supply staff may wish to revisit their contingency planning documents. Contingency planning documents are a primary means to ensure that, through emergency preparedness, a community will minimize their risk of being without safe and adequate water. Finally, the water supply staff is encouraged to review their cross connection control program to ensure that it remains current and viable. Cross connections to either the water treatment plant (for example, at bulk water loading stations) or in the distribution system may negate all source water protection initiatives provided by the community..

Source Water Assessment Program

FACT SHEET

GRANVILLE

PUTNAM COUNTY

Prepared in cooperation with the U.S. Geological Survey.

Information and data used in the preparation of this Fact Sheet are provided by the Illinois EPA and are subject to revision.

IMPORTANCE OF SOURCE WATER:

The Viallage of Granville (Facility #1550050) has two public water supply wells. Well #1 (IEPA #11590) and Well #2 (IEPA #11591) produce 186,500 gallons per day to an estimated population of 1,402 through 644 service connections. The facility provides water to the Village of Mark and Oak Park Estates MHP.

WATER SUPPLIES THAT OBTAIN SOURCE WATER FROM THIS FACILITY:

Facility Number	Facility Name	Status	Population
1550010	OAK PARK ESTATES	A	150
1550250	MARK	A	500

SOURCE OF WATER SUPPLY:

Well #1 is located at the village garage at the southeast corner of Main and High Streets. Well #2 is located on the south of the intersection of Tomlinson and Colby Streets. Wells #1 and #2 pump 135 and 170 gallons per minute and have a production capacity of 439,200 gallons per day. The wells are 1,742 and 1,782 feet deep and utilize deep bedrock aquifer, which are overlain by relatively impermeable till interbedded within sand and gravel. Permeability is the ability of a soil or sediment to transmit fluids. The aquifer utilized is considered confined by the Illinois EPA, therefore is not considered geologically sensitive.

WELL DATA FOR THIS FACILITY:

Well ID	Well Description	Status	Depth (Feet)	Min Setback (Feet)	Aquifer Description
11590	WELL NO 1 IN CITY GARAGE	A	1742	200	DEEP BEDROCK
11591	WELL NO 2	A	1782	200	DEEP BEDROCK

SOURCE WATER QUALITY:

The public water supply wells at Granville were sampled as part of the Statewide Groundwater Monitoring Network on June 9, 1987. The well samples were analyzed for volatile organic compounds (VOC) and inorganic chemicals (IOC). The VOC analyses performed detected no quantifiable levels of organic chemicals in either well. The IOC analyses performed found the water from both wells to have an elevated level of total chlorides, which is naturally occurring. Total Chloride was detected at a level of 304 and 308 parts per billion (ppb), in Wells #1 and #2, respectively which is above the Groundwater Quality Standards of 200 ppb for chloride established in 35 Illinois Administrative Code Part 620.410.

FINISHED WATER QUALITY:

Finished water quality data tables of monitored parameters, contaminants detected, health advisory information,

drinking water standards or maximum contaminant levels are available at http//www.epa.gov/ogwdw. Similar information is also available in the Consumer Confidence Report supplied by the water supply to its customers. A review of this information does not indicate levels of organic or inorganic compounds which exceed the drinking water quality standards. Radium and Alpha emitters were detected in radionuclide analyses done in 1999. Alpha emitters were detect at a level of 39 picoCuries per liter (pCi/l) and combined radium was detected at a level of 12.2 pCi/l, the maximum contaminant levels (MCL) are 15 and 5 pCi/l respectively.

POTENTIAL SOURCES OF CONTAMINATION:

The sites labeled on the Wellhead Protection Planning Map and described in the following tables are considered "potential" sources of contamination. (Maps and tables are not available in the Visually Impaired Accessible version. However, the information presented in the maps and tables is summarized within the following text sections of this fact sheet.) The Illinois EPA performed a detailed Well Site Survey in 1992 to identify potential sources of contamination to the community's wells. These sources are identified based on the nature of their activity, the availability of data in electronic databases, and their geographic proximity to the source water protection area. In addition, the Illinois EPA made use of information from its leaking underground storage tank database (http://epadata.epa.state.il.us/land/ust/search.asp) and site remediation program database (http://epadata.epa.state.il.us/land/srp/search.asp) to further assess potential sources of contamination to the community's source water. These databases include information from the Illinois EPA Division of Land Pollution Control (LPC) and the Illinois Emergency Management Agency (IEMA). The following is a list of facilities contained within these databases. As a result of multiple possible contamination sources, individual sites may be listed in the table more than once in relation to a well.

OTHER IDENTIFIED POTENTIAL SOURCES:

For this community water supply, no additional potential sources of contamination have been identified beyond those in Illinois EPA databases.

SUSCEPTIBILITY TO CONTAMINATION:

Based on information obtained in a Well Site Survey published in 1992 by the Illinois EPA, several potential sources are located within 1,000 feet of the wells.

The Illinois EPA has determined that the Granville Community Water Supply's source water is not suspectibile to contamination. This determination is based on a number of criteria including; monitoring conducted at the wells; monitoring conducted at the entry point to the distribution system; and available hydrogeologic data on the wells.

Furthermore, in anticipation of the U.S. EPA's proposed Ground Water Rule, the Illinois EPA has determined that the Granville Community Water Supply is not vulnerable to viral contamination. This determination is based upon the evaluation of the following criteria during the Vulnerability Waiver Process: the community's wells are properly constructed with sound integrity and proper siting conditions; a hydraulic barrier exists which should prevent pathogen movement; all potential routes and sanitary defects have been mitigated such that the source water is adequately protected; monitoring data did not indicate a history of disease outbreak; and the sanitary survey of the water supply did not indicate a viral contamination threat. Because the community's wells are constructed in a confined aquifer, which should prevent the movement of pathogens into the wells, well hydraulics were not considered to be a significant factor in the susceptibility determination. Hence, well hydraulics were not evaluated for this system ground water supply.

SOURCE WATER PROTECTION EFFORTS:

The Illinois Environmental Protection Act provides minimum protection zones of 200 feet for your wells. These minimum protection zones are regulated by the Illinois EPA. To further reduce the risk to source water, the Facility has implemented a wellhead protection program which includes the proper abandonment of potential routes of groundwater contamination and correction of sanitary defects at the water treatment facility. This effort resulted in the community water supply receiving a special exception permit from the Illinois EPA which allows a reduction in monitoring. The outcome of this monitoring reduction has saved the community considerable laboratory analysis costs.

To further minimize the risk to the facility's groundwater supply, the Illinois EPA recommends that three additional activities be assessed. First, the water supply may wish to enact a "maximum setback zone" ordinance. These ordinances are authorized by the Illinois Environmental Protection Act and allow county and municipal officials the opportunity to provide additional protection up to a fixed distance, normally 1,000 feet from their wells. Second, the water supply staff may wish to revisit their contingency planning documents. Contingency planning documents are a primary means to ensure that, through emergency preparedness, a community will minimize their risk of being without safe and adequate water. Finally, the water supply staff is encouraged to review their cross connection control program to ensure that it remains current and viable. Cross connections to either the water treatment plant (for example, at bulk water loading stations) or in the distribution system may negate all source water protection initatives provided by the community.

PUTNAM COUNTY

Prepared in cooperation with the U.S. Geological Survey.

Information and data used in the preparation of this Fact Sheet are provided by the Illinois EPA and are subject to revision.

Illinois EPA PWS Number: **1550250**

For the purpose of the Source Water Assessment Program (SWAP), this community water supply (CWS) purchases water from another CWS. The current procedure for a purchasing water supply indicates that the source water information for this CWS is presented in the SWAP Fact Sheet of the parent supply (the water supply from which the water originates). Therefore, please refer to the parent supply's SWAP Fact Sheet for an assessment of this CWS's source water. The parent CWS for the supply you requested is listed below with its source water type and county. Some CWSs that purchase their water have wells as back-up supplies; however, these wells are not the primary source of water supply and are not considered as part of this assessment program.

Subject: RE: Community and Non-Community Water Supplies - Putnam Counry

Dear Stu,

As far as the non-communities we are responsible for at the local level, none of them are located in that area. However, the state also covers non-community wells in our area because they fall in a different category so I am forwarding this email to our Regional State Health Department in Peoria, IL. The contact is John Smet. Email: john.smet@illinois.gov. Hopefully he will get back to you regarding the non-community wells the state is responsible for.

Sincerely,

Andrea Gress

Subject: Community and Non-Community Water Supplies - Putnam Counry

To: Bureau and Putnam County Health Department

As required by the IEPA, and on behalf of the Hennepin Power Station, located in Putnam County, Illinois (Township 33 North, Range, 2 West, Section 26) Kelron Environmental is conducting a water well survey of potable wells within 1 mile of the property.

I have done the web database searches and obtained information from the IEPA, ISGS, and ISWS and wanted to confirm that there are no community water supply wells within 1 mile of the Hennepin Power Station and the only non-community water supply well(s) are located at the Exolon Corporation in the southeast quarter of Section 26. The IEPA website showed there to be one non-community water supply well on Exolon property used for potable purposes, although there are apparently at least two other wells which may be active or inactive for industrial (non-potable) use.

I would appreciate it if you could confirm this information or provide me with a contact person in your office with whom I can communicate via mail or phone.

Thank you very much.

Notes:

Data do not include Field Replicates. Available upon request.
EWLI - electronic water level indicator.

(d) dissolved
(t) total
(t/d)* Total analyses Quarter's 2 and 3, 2013; dissolved analyses Quarter 4, 2013 and Quarter 1, 2014.
** Sulfate measured as total in samples from wells 33 and 34 during Quarter 4, 2013.

- - Not applicable.
- - - - Not sampled or insufficient groundwater for sampling and/or anlalysis.
ns No standard.

< ND - Not detected at the Reporting Limit

0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410)

Notes:

mg/L Milligrams per Liter.

< ND - Not detected at the Reporting Limit.

J Analyte detected below Reporting Limit.

- - No Class I Groundwater Quality Standard for the listed constituent in IAC Section 620.410, Chapter I, Subtitle F, Title 35.

---- Not sampled or insufficient groundwater for sampling and analysis.

* PCBs - Polychlorinated Biphenyls. Individual PCB compounds (Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, and Aroclor 1260) are each <0.0005 mg/L.

0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410).

Appendix G3: Organic Parameter Groundwater Quality Results June 2013 - Hydrogeologic Site Characterization Report

Notes:
mg/L Milligrams per Liter.
< ND - Not detected at the Reporting Limit.
J Analyte detected below Reporting Limit.
- - No Class I Groundwater Quality Standard for the listed constituent in IAC Section 620.410, Chapter I, Subtitle F, Title 35.
---- Not sampled or insufficient groundwater for sampling and analysis.
* PCBs - Polychlorinated Biphenyls. Individual PCB compounds (Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, and Aroclor 1260) are each <0.0005 mg/L.
0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410).

Appendix G3: Organic Parameter Groundwater Quality Results June 2013 - Hydrogeologic Site Characterization Report
West Ash Pond System, Hennepin Power Station

Notes:

mg/L Milligrams per Liter.

< ND - Not detected at the Reporting Limit.

J Analyte detected below Reporting Limit.

- - No Class I Groundwater Quality Standard for the listed constituent in IAC Section 620.410, Chapter I, Subtitle F, Title 35.

---- Not sampled or insufficient groundwater for sampling and analysis.

* PCBs - Polychlorinated Biphenyls. Individual PCB compounds (Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, and Aroclor 1260) are each <0.0005 mg/L.

0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410).

Appendix G3: Organic Parameter Groundwater Quality Results June 2013 - Hydrogeologic Site Characterization Report
West Ash Pond System, Hennepin Power Station

Notes:
mg/L Milligrams per Liter.
< ND - Not detected at the Reporting Limit.
J Analyte detected below Reporting Limit.
- - No Class I Groundwater Quality Standard for the listed constituent in IAC Section 620.410, Chapter I, Subtitle F, Title 35.
---- Not sampled or insufficient groundwater for sampling and analysis.
* PCBs - Polychlorinated Biphenyls. Individual PCB compounds (Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, and Aroclor 1260) are each <0.0005 mg/L.
0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410).

Appendix G3: Organic Parameter Groundwater Quality Results June 2013 - Hydrogeologic Site Characterization Report
West Ash Pond System, Hennepin Power Station

Notes:
mg/L Milligrams per Liter.
< ND - Not detected at the Reporting Limit.
J Analyte detected below Reporting Limit.
- - No Class I Groundwater Quality Standard for the listed constituent in IAC Section 620.410, Chapter I, Subtitle F, Title 35.
---- Not sampled or insufficient groundwater for sampling and analysis.
* PCBs - Polychlorinated Biphenyls. Individual PCB compounds (Aroclor 1016, Aroclor 1221, Aroclor 1232, Aroclor 1242, Aroclor 1248, Aroclor 1254, and Aroclor 1260) are each <0.0005 mg/L.
0.42 Parameter concentration exceeds Class I groundwater standard (IAC Part 620 Section 410).

Appendix G3: Organic Parameter Groundwater Quality Results June 2013 - Hydrogeologic Site Characterization Report
West Ash Pond System, Hennepin Power Station

Subject: Periodic History of Construction Report Update Letter
USEPA Final CCR Rule, 40 CFR §257.73(c)
Hennepin Power Plant
Hennepin, Illinois

Hennepin

At the request of Dynegy Midwest Generation, LLC (DMG), Geosyntec Consultants (Geosyntec) has prepared this Letter to documents updates to the Initial History of Construction (HoC) report for the Hennepin Power Plant (HPP), also known as the Hennepin Power Station (HEN). The Initial HoC report was prepared by AECOM in October of 2016 [1] in accordance with 40 Code of Federal Regulations (CFR) §257.73(c) of the United States Environmental Protection Agency (USEPA) Coal Combustion Residuals Rule, known as the CCR Rule [2]. This letter also includes information required by Section 845.220(a)(1)(B) (Design and Construction Plans) of the state-specific Illinois Environmental Protection Agency (IEPA) Part 845 CCR Rule [3] that is not expressly required by §257.73(c).

BACKGROUND

The CCR Rule required that, by October 17, 2016, Initial HoC reports to be compiled for existing CCR surface impoundments with: (1) a height of five feet or more and a storage volume of 20 acre-feet or more, or (2) a height of 20 feet or more. The Initial HoC report was required to contain, to the extent feasible, the information specified in 40 CFR §257.73(c)(1)(i)-(xii). The Initial HoC report for HPP, which included four existing CCR surface impoundments, the Old West Polishing Pond (OWPP), Old West Ash Pond (Pond No. 1 and Pond No. 3, also known as the OWAP), Ash Pond No. 2 (AP2), and the East Ash Pond (EAP), was prepared and subsequently posted to DMG's CCR Website prior to October 17, 2016.

The CCR Rule requires that Initial HoC to be updated if there is a significant change to any information complied in the Initial HoC report, as listed below:

engineers | scientists | innovators

§ 257.73(c)(2): If there is a significant change to any information complied under paragraph (c)(1) of this section, the owner or operator of the CCR unit must update the relevant information and place it in the facility's operating record as required by § 257.105(f)(9).

DMG retained Geosyntec to review the Initial HoC report, review reasonably and readily available information for the OWPP, OWAP, AP2, EAP generated since the Initial HoC report was prepared, and perform a site visit to HPP to evaluate if significant changes may have occurred since the Initial HoC report was prepared. This Letter contains the results of Geosyntec's evaluation and documents significant changes that have occurred at the OWPP, OWAP, AP2, and EAP, as they pertain the requirements of §257.73(c)(1)(i)-(xii)

UPDATES TO HISTORY OF CONSTRUCTION REPORT

Geosyntec's evaluation for the HPP OWPP, OWAP, AP2, and EAP determined that no known significant changes requiring updates to the information in the Initial HoC report pertaining to §257.73(c)(1)(ii), (iv), (v), (vi), (vii), (xi), and (xii) of the CCR Rule had occurred since the Initial HoC report was developed.

However, Geosyntec's evaluation determined that significant changes at the HPP EAP pertaining to §257.73(c)(1)(i), (iii), (viii), (ix), and (x) of the CCR Rule had occurred since the Initial HoC report had been developed. Additionally, information how long the CCR EAP and been operating and the types of CCR in the impoundment, as required by Section 845.220(a)(1)(B) of the Part 845 Rule were not included in the Initial HoC report, as this information is not required by the CCR Rule. Each change and the subsequent updates to the Initial HoC report is described within this section.

Hennepin

Section 845.220(a)(1)(B): A statement of ... how long the CCR surface impoundment has been in operation, and the types of CCR that have been placed in the surface impoundment.

East Ash Pond

The EAP was in operation from 1996 until the HPP was retired in December of 2019, for a total of approximately 23 years [1]. Since December of 2019 the EAP has not been actively receiving CCR but has not yet been closed. As of the date of this report, the EAP has been present for approximately 25 years.

CCR placed in the EAP has included bottom ash and fly ash, in addition to other non-CCR waste streams [1].

Old West Polishing Pond and Old West Ash Pond

The OWAP and OWPP were in operation from 1952 to approximately 1996, for a total of approximately 44 years. The OWAP and OWPP did not receive CCR after 1996 but was not closed until 2020. The OWAP and OWPP were present for a total of approximately 68 years prior to closure.

CCR placed in the OWAP and OWPP included fly ash and bottom ash.

Ash Pond No. 2

AP2 was in operation from 1958 until sometime between 2003 and 2009, for a total of approximately 45 to 51 years. AP2 did not receive CCR after sometime between 2003 and 2009, but was not closed until 2020. AP2 was present for a total of approximately 62 years.

CCR placed in AP2 included fly ash and bottom ash.

§ 257.73(c)(1)(i): The name and address of the person(s) owning or operating the CCR unit; the name associated with the CCR unit; and the identification number of the CCR unit if one has been assigned by the state.

State identification numbers (IDs) for the OWPP, OWAP, AP2, and EAP have been assigned by the Illinois Environmental Protection Agency (IEPA). Each ID is listed in **Table 1**.

Table 1 – Results of Updated Discharge Capacity Calculations

CCR Surface Impoundment	State ID
Old West Polishing Pond (OWPP)	W1550100002-01
Old West Ash Pond (OWAP)	W1550100002-03
Ash Pond No. 2 (AP2)	W1550100002-04
East Ash Pond (EAP)	W1550100002-05

§ 257.73(c)(1)(iii): A statement of the purpose for which the CCR unit is being used.

The OWPP, OWAP, and EAP2 were closed in 2020, in substantial compliance with the written closure plans posted to DMG's CCR Website ([4], [5], [6]), and as documented by certified Notification of Completion of Closures posted to DMG's CCR Website ([7], [8]). Therefore, the OWAP and EAP2 are no longer capable of storing additional CCR or free liquids, and all CCR was removed from the OWPP as part of closure-by-removal.

The HPP was retired in December of 2019, with the generation of electricity ceased at that time. Therefore, the EAP is no longer being used to actively store and dispose of new CCR, as CCR is no longer being generated by the HPP. The EAP also received inflows from East

Hennepin

Ash Pond No. 2 and the Coal Pile Runoff Pond; these inflows have also ceased as part of plant closure.

§ 257.73(c)(1)(viii): A description of the type, purpose, and location of existing instrumentation.

Instrumentation monitoring at the OWPP, OWAP, and EAP is no longer required as these CCR surface impoundments were closed in accordance with §257.102 ([7], [8]), and the instrumentation network was modified at that time. Therefore, the instrumentation locations shown in Appendix C of the Initial HoC report are no longer applicable to the OWPP, OWAP, and EAP.

§ 257.73(c)(1)(ix): Area-capacity curves for the CCR unit.

An updated area-capacity curve was prepared for the EAP in 2021 and is provided in **Figure 1**.

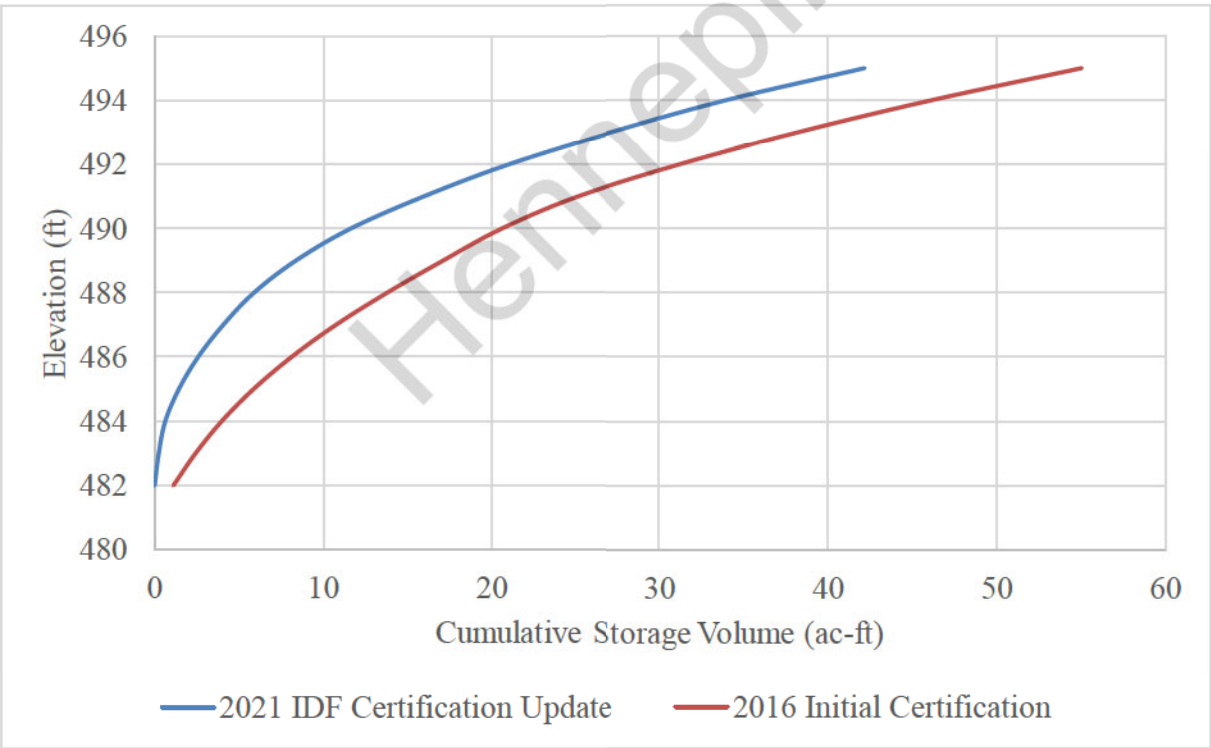

Figure 1 – Area-Capacity Curve for East Ash Pond

§ 257.73(c)(1)(x): A description of each spillway and diversion design features and capacities and calculations used in their determination.

Updated discharge capacity calculations for the existing spillways of the EAP were prepared in 2021 using HydroCAD 10 modeling software. The calculations indicate that the EAP has sufficient storage capacity and will not overtop the embankments during the 1,000-year, 24-hour, storm event. The results of the calculations are provided in **Table 2**.

Table 2 – Results of Updated Discharge Capacity Calculations

	East Ash Pond
Approximate Berm Minimum Elevation[1], ft	492.0
Approximate Emergency Spillway Elevation[1], ft	Not Applicable
Starting Water Surface Elevation[1] (SWSE), ft	490.0
Peak Water Surface Elevation[1] (PWSE), ft	491.4
Time to Peak, hr	16.8
Surface Area[2], ac	5.0
Storage[3], ac-ft	6.3

Notes:
[1]Elevations are based on the NAVD88 datum
[2]Surface area is defined as the water surface area at the PWSE
[3]Storage is defined as the volume between the SWSE and PWSE

Hennepin

The OWPP, OWAP, and EAP2 no longer retain free water as both CCR surface impoundments were closed in 2020 ([7], [8]). Therefore, the spillways are no longer present and the information regarding the spillways of these structures, as presented in the Initial HoC report, is no longer applicable to the OWPP, OWAP, and EAP2.

CLOSING

This letter has been prepared to document Geosyntec's evaluation of changes that have occurred at the OWPP, OWAP, AP2, and EAP at the HPP since the Initial HoC was developed, based on reasonably and readily available information provided by DMG, observed by Geosyntec during the site visit, or generated by Geosyntec as part of subsequent calculations.

Sincerely,

Lucas P. Carr, P.E.
Senior Engineer

John Seymour, P.E.
Senior Principal

RE: History of Construction
USEPA Final CCR Rule, 40 CFR § 257.73(c)
Hennepin Power Station
Hennepin, Illinois

On behalf of Dynegy Midwest Generation, LLC, AECOM has prepared the following history of construction for the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond at the Hennepin Power Station in accordance with 40 CFR § 257.73(c).

BACKGROUND

40 CFR § 257.73(c)(1) requires the owner or operator of an existing coal combustion residual (CCR) surface impoundment that either (1) has a height of five feet or more and a storage volume of 20 acre-feet or more, or (2) has a height of 20 feet or more to compile a history of construction by October 17, 2016 that contains, to the extent feasible, the information specified in 40 CFR § 257.73(c)(1)(i)–(xii).

The history of construction presented herein was compiled based on existing documentation, to the extent that it is reasonably and readily available (see 80 Fed. Reg. 21302, 21380 [April 17, 2015]), and AECOM's site experience. AECOM's document review included construction drawings, geotechnical investigations, operation and maintenance information, etc. for Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond at the Hennepin Power Station.

AECOM

HISTORY OF CONSTRUCTION

§ 257.73(c)(1)(i): The name and address of the person(s) owning or operating the CCR unit; the name associated with the CCR unit; and the identification number of the CCR unit if one has been assigned by the state.

Owner: Dynegy Midwest Generation, LLC

Address: 1500 Eastport Plaza Drive
Collinsville, IL 62234

CCR Units: Old West Polishing Pond
Old West Ash Pond (Pond No. 1 and Pond No. 3)
Ash Pond No. 2
East Ash Pond, IDNR Dam ID No. IL50363

The Old West Polishing Pond, Old West Ash Pond, and Ash Pond No. 2 do not have a state assigned identification number.

§ 257.73(c)(1)(ii): The location of the CCR unit identified on the most recent USGS $7^1/_2$ or 15 minute topographic quadrangle map or a topographic map of equivalent scale if a USGS map is not available.

The locations of the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond have been identified on an USGS 7-1/2 minute topographic quadrangle map in **Appendix A**.

§ 257.73(c)(1)(iii): A statement of the purpose for which the CCR unit is being used.

The following captures the purpose of each CCR unit:

- The Old West Polishing Pond (inactive) was used to store and dispose fly ash and bottom ash and is currently being used to clarify stormwater runoff from the Old West Ash Pond prior to discharge in accordance with the station's NPDES permit.
- The Old West Ash Pond (inactive) was used to store and dispose fly ash and bottom ash.
- The Ash Pond No. 2 (inactive) was used to store and dispose fly ash, bottom ash, and other non-CCR waste streams including coal pile runoff.
- The East Ash Pond is being used to store and dispose bottom ash, fly ash, and other non-CCR waste and to clarify process water prior to discharge in accordance with the station's NPDES permit.

Notice of intent to close the Old West Polishing Pond, Old West Ash Pond, and Ash Pond No. 2 was provided in November 2015.[1]

[1] This history of construction report was prepared on a facility-wide basis for CCR surface impoundments at the Hennepin Power Station. The inclusion of the Old West Polishing Pond, Old West Ash Pond, and Ash Pond No. 2 in this history of construction report does not concede and should not be construed to concede that the Old

§ 257.73(c)(1)(iv): The name and size in acres of the watershed where the CCR unit is located.

The Hennepin Power Station and the above-referenced CCR units are located at the western edge of the Depue Lake-Illinois River Watershed with a 12-digit Hydrologic Unit Code (HUC) of 071300010804 and a drainage area of 44,525 acres (USGS 2016).

§ 257.73(c)(1)(v): A description of the physical and engineering properties of the foundation and abutment materials on which the CCR unit is constructed.

Physical properties of the foundation materials for the Old West Polishing Pond and Old West Ash Pond are described as cohesive material underlain by granular material. The cohesive material consists of lean clay, gravelly clay, silt, clayey silt, and sandy silt. The consistency of the cohesive material varies from very soft to medium stiff. The granular material consists of silty sand and clayey gravel. The relative density of the granular materials varies from loose to very dense and generally increases with depth. An available summary of the engineering properties of the foundation materials for the Old West Polishing Pond and Old West Ash Pond is presented in **Table 1** below. The engineering properties are based on previous geotechnical explorations and laboratory testing.

Table 1. Summary of Material Engineering Properties for the Old West Polishing Pond and Old West Ash Pond

Layer	Unit Weight (pcf)	Total (undrained) Shear Strength Parameters		Effective (drained) Shear Strength Parameters	
		ϕ (deg)	*c (psf)*	*ϕ′ (deg)*	*c′ (psf)*
CL (soft)	120	0	500	28	0
CL (medium stiff gravely clay)	120	28	0	28	0
ML (soft to medium stiff)	125	28	0	28	0
CL-ML (very soft)	120	0	400	26	0
SM (very loose)	125	28	0	28	0
GC (dense)	130	34	0	34	0
GC (very dense)	130	36	0	36	0
Fill: GC (very dense)	130	34	50	34	0

West Polishing Pond, Old West Ash Pond, and Ash Pond No. 2 are subject to the Design Criteria or all Operating Criteria in the CCR Rule.

The Old West Polishing Pond and Old West Ash Pond are enclosed impoundments with dikes and do not have abutments.

Physical properties of the foundation and abutment materials for Ash Pond No. 2 and the East Ash Pond are described as gravel materials with varying amounts of silt and clay. The relative density of the gravel is medium dense to very dense. An available summary of the engineering properties of the foundation materials for Ash Pond No. 2 and the East Ash Pond is presented in **Table 2** below. The engineering properties are based on previous geotechnical explorations and laboratory testing.

Table 2. Summary of Foundation and Abutment Material Engineering Properties for the Ash Pond No. 2 and East Ash Pond

Material	Unit Weight (pcf)	Effective (drained) Shear Strength Parameters		Total (undrained) Shear Strength Parameters	
		c' (psf)	Φ' (°)	c (psf)	Φ (°)
Alluvial Foundation	135	0	38	0	38

§ 257.73(c)(1)(vi): A statement of the type, size, range, and physical and engineering properties of the materials used in constructing each zone or stage of the CCR unit; the method of site preparation and construction of each zone of the CCR unit; and the approximate dates of construction of each successive stage of construction of the CCR unit.

Physical properties of the embankment materials for the Old West Polishing Pond and Old West Ash Pond are described as gravel with occasional zones of clayey sand and lean clay. The gravel has a general relative density of very dense. An available summary of the engineering properties of the embankment materials for the Old West Polishing Pond and Old West Ash Pond is presented in **Table 1** above. The engineering properties are based on previous geotechnical explorations and laboratory testing.

The physical properties of Ash Pond No. 2 embankment construction materials are described in this paragraph. The original embankments are constructed of sand with varying amounts of coal pieces and gravel. The initial embankment raise is constructed of silty clay, clayey sand, sand, and gravel and the later embankment raise is constructed with layers of lean clay, silty clay, clayey silt, clayey, and gravel. An available summary of the engineering properties of the embankment materials for Ash Pond No. 2 is presented in **Table 3** below. The engineering properties are based on previous geotechnical explorations and laboratory testing.

Table 3. Summary of Construction Material Engineering Properties for Ash Pond No. 2

Material	Unit Weight (pcf)	Effective (drained) Shear Strength Parameters		Total (undrained) Shear Strength Parameters	
		c' (psf)	Φ' (°)	c (psf)	Φ (°)
Fill: GP-GM (medium dense)	125	0	32	0	32
Fill: CL (hard)	120	0	32	4000	0
Fill: ML (hard)	120	0	32	4500	0
Fill: SC (medium dense)	120	0	28	0	28

Physical properties of the embankment materials for the East Ash Pond are described as clayey silt and clay. The consistency of both the clayey silt and clay ranges from stiff to hard. The original pond surface is lined with a 4-foot thick compacted clay layer of 1.0 x 10^{-7} cm/s underlain by a 1-foot thick sand layer. The liner system of the embankment raise consists of a (from top to bottom) 45 mil reinforced polyethylene geomembrane, a 1-foot thick clay layer, and an 8 oz/sy polypropylene geotextile. A typical cross section profile of the liner system is shown on drawing C-56 presented in **Appendix B**. An available summary of the construction material engineering properties for the East Ash Pond is presented in **Table 4** below. The engineering properties are based on previous geotechnical explorations and laboratory testing.

Table 4. Summary of Construction Material Engineering Properties for the East Ash Pond

Material	Unit Weight (pcf)	Effective (drained) Shear Strength Parameters		Total (undrained) Shear Strength Parameters	
		c' (psf)	Φ' (°)	c (psf)	Φ (°)
Embankment Fill	105	30	32	2500	0
Liner System	120	60	30	2500	0

The method of site preparation and construction of the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and the original East Ash Pond are not reasonably and readily available. Site preparation and construction of the 2003 East Ash Pond liner raise were completed in accordance with the applicable construction specification (see § 257.73(c)(1)(xi) below).

Reasonably and readily available approximate dates of construction of each successive stage of construction of the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond are provided in **Table 5** below.

Table 5. Approximate dates of construction of each successive stage of construction.

Date	Event
1951 to 1952	Construction of historical Ash Pond No. 1
1958	Construction of Ash Pond No. 2
Late 1960's	Construction of historical Ash Pond No. 3
1978	Embankment raise of Ash Pond No. 2
1985	Embankment raise of Ash Pond No. 2 to elevation 484 feet and Ash Pond No. 3 (Old West Ash Pond) to elevation 460 feet
1988 to 1989	Embankment raise of Old West Ash Pond to elevation 465 feet that merged historical Ash Pond No. 1 and Ash Pond No. 3 into one single pond and created the Old West Polishing Pond
1989	Embankment raise of Ash Pond No. 2 to elevation 494 feet
1995 to 1996	Construction of East Ash Pond
2003	Embankment liner raise of East Ash Pond
2009 to 2010	Eastern portion of Ash Pond No. 2 was removed to facilitate construction of the Leachate Pond
2011	Landfill Cell 1 was constructed over placed CCR in Ash Pond No. 2 adjacent to the Leachate Pond
2014	North Embankment tree removal, grading, and vegetation re-establishment of Ash Pond No. 2

§ 257.73(c)(1)(vii): At a scale that details engineering structures and appurtenances relevant to the design, construction, operation, and maintenance of the CCR unit, detailed dimensional drawings of the CCR unit, including a plan view and cross sections of the length and width of the CCR unit, showing all zones, foundation improvements, drainage provisions, spillways, diversion ditches, outlets, instrument locations, and slope protection, in addition to the normal operating pool surface elevation and the maximum pool surface elevation following peak discharge from the inflow design flood, the expected maximum depth of CCR within the CCR surface impoundment, and any identifiable natural or manmade features that could adversely affect operation of the CCR unit due to malfunction or mis-operation.

Drawings that contain items pertaining to the requested information for the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond are listed in **Table 6** below. Items marked as "Not Available" are items not found during a review of the reasonably and readily available record documentation.

Table 6. List of drawings containing items pertaining to the information requested in § 257.73(c)(1)(vii).

	Old West Polishing Pond	Old West Ash Pond	Ash Pond No. 2	East Ash Pond
Dimensional plan view (all zones)	HEN1-B460-2	HEN1-B460-1 to 2	HEN1-B461, HEN1-C117	HEN1-C55
Dimensional cross sections	HEN1-B452 to B457	HEN1-B452 to B457	HEN1-B458-1 to 7, Berm Modification Drawings 7 to 9	HEN1-C56 to C59
Foundation Improvements	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Drainage Provisions	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Spillways and Outlets	Not Available	Not Available	Not Applicable	HEN1-C8 to C9, HEN1-C109, HEN1-C113
Diversion Ditches	Not Applicable	Not Applicable	Not Applicable	Not Applicable
Instrument Locations	Figure 2D	Figure 2C	Figure 2A	Figure 2B
Slope Protection	Not Available	Not Available	Berm Modification Drawings 3 to 9	HEN1-C56 to C59
Normal Operating Pool Elevation	Not Available	Not Available	Not Available	Not Available
Maximum Pool Elevation	Not Available	Not Available	Not Available	Not Available
Approximate Maximum Depth of CCR in 2016	11 feet	15 feet	46 feet	35 feet

All drawings referenced in **Table 6** above can be found in **Appendix B** and **Appendix C**.

Based on the review of the drawings listed above, no natural or manmade features that could adversely affect operation of these CCR units due to malfunction or mis-operation were identified.

§ 257.73(c)(1)(viii): A description of the type, purpose, and location of existing instrumentation.

Existing instrumentation consists of open-standpipe piezometers installed in 2015. The purpose of the piezometers is to measure the pore water pressures within the embankments of the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond. There are seven (7) existing piezometers within the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond. A location map of the existing instrumentation is presented in **Appendix C**.

§ 257.73(c)(1)(ix): Area-capacity curves for the CCR unit.

Area-capacity curves for the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond are not reasonably and readily available.

§ 257.73(c)(1)(x): A description of each spillway and diversion design features and capacities and calculations used in their determination.

The Old West Polishing Pond contains a 24-inch diameter corrugated metal pipe (CMP) outlet that discharges stormwater to the Illinois River in accordance with the station's NPDES permit. Current capacity and calculation information for the Old West Polishing Pond's discharge capability is not reasonably and readily available.

The Old West Ash Pond contains a 24-inch dia. pipe culvert. Stormwater collected within the CCR unit drains via surface flow and through the pipe culvert into the Old West Polishing Pond. Current capacity and calculation information for the Old West Ash Pond's discharge capability is not reasonably and readily available.

The Ash Pond No. 2 does not contain a spillway or diversion feature. Stormwater collected within the CCR unit drains via surface flow into the East Ash Pond. Current capacity and calculation information for the Ash Pond No. 2's discharge capability is not reasonably and readily available.

The East Ash Pond contains two outlet structures. The southeast outlet is a 5-foot wide stop-log structure that is connected to a 36-inch diameter reinforced concrete pipe (RCP). The 36-inch diameter RCP discharges into the East Polishing Pond. The northeast outlet, located on the northeast corner of the East Ash Pond, is a headwall structure connected to an 18-inch diameter RCP. The 18-inch diameter RCP discharges into the East Leachate Pond. In 2016, the discharge capacity of the East Ash Pond was evaluated using HydroCAD 10 software modeling a 1,000-year, 24-hour rainfall event. The model results indicate that the East Ash Pond has enough storage capacity and will not overtop the embankment during the 1,000-year, 24-hour storm event. The results of the HydroCAD 10 analysis are presented below in **Table 7**.

Table 7. Results of HydroCAD 10 analysis

	East Ash Pond
Approximate Minimum Berm Elevation[1] (ft)	493.0
Approximate Emergency Spillway Elevation[1] (ft)	Not Applicable
Starting Pool Elevation[1] (ft)	490.4
Peak Elevation[1] (ft)	492..2
Time to Peak (hr)	12.5
Surface Area (ac)	6.5
Storage[2] (ac-ft)	8.4

Note: 1. Elevations are based on NAVD88 datum
2. Storage given is from Starting Pool Elevation to Peak Elevation.

§ 257.73(c)(1)(xi): The construction specifications and provisions for surveillance, maintenance, and repair of the CCR unit.

The construction specifications for Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and the original East Ash Pond are not reasonably and readily available. The construction specification for the 2003 East Ash Pond liner raise is located in *Specification J-2616, Rev. A* (presented in **Appendix D**).

The provisions for surveillance, maintenance, and repair of the Old West Polishing Pond and Old West Ash Pond are located in *Hennepin Power Station; West Ash Disposal Pond Maintenance Plan* (2013) (presented in **Appendix E**). The provisions for surveillance, maintenance, and repair of Ash Pond No. 2 are located in *Hennepin Power Station; Old East Ash Disposal Pond Maintenance Plan* (2013) (presented in **Appendix F**). The provisions for surveillance, maintenance, and repair of the East Ash Pond are located in *Hennepin Power Station; East Ash Disposal Pond Maintenance Plan* (2014) (presented in **Appendix G**).

The operations and maintenance plans for the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond are currently being revised by Dynegy Midwest Generation, LLC.

§ 257.73(c)(1)(xii): Any record or knowledge of structural instability of the CCR unit.

There is no record or knowledge of structural instability of the Old West Polishing Pond, Old West Ash Pond, Ash Pond No. 2, and East Ash Pond at the Hennepin Power Station.

NOTES:

1. TOPOGRAPHIC MAP USED FOR THE BACKGROUND WAS SUPPLIED BY DYNEGY MIDWEST GENERATION.
2. PLANT COORDINATE SYSTEM SHOWN ON THE DESIGN DRAWINGS WAS TAKEN FROM EXISTING HENNEPIN DRAWING CE-HEN1-C03.
3. VENTS AS SHOWN ON DETAIL C-58-1 SHALL BE LOCATED AT EL.492.0. VENTS SHALL BE PROVIDED AT 100' INTERVAL.
4. TWO LAYERS OF 45 MIL. THICK REINFORCED POLYPROPYLENE GEOMEMBRANE SHALL BE USED UNDER THE FABRIFORM REVETMENT AREAS AS SHOWN IN THE SECTIONS. ONLY ONE LAYER OF 45 MIL. REINFORCED POLYPROPYLENE GEOMEMBRANE SHALL BE USED FOR THE REST OF THE POND LINING.
5. THE CLAY LINER SHALL BE KEPT MOIST TO AVOID CRACKING DUE TO DESICCATION UNTIL THE GEOMEMBRANE IS INSTALLED.
6. 6" OF TOPSOIL SHALL BE REMOVED FROM THE POND SLOPES. USABLE TOPSCIL SHALL BE STOCKPILED ON THE SITE FOR USE FOR SEEDING AND LANDSCAPING. UNSUITABLE MATERIAL SHALL BE HAULED AWAY FOR DISPOSAL.

DETAIL 1
30" SILT FENCE DETAIL
N.T.S.

SILT FENCE NOTES:

1. SILT FENCE SHALL BE PLACED ON LEVEL GRADE, WHERE POSSIBLE, AND BOTH ENDS OF THE SILT FENCE SHALL BE EXTENDED UP THE SLOPE.
2. SILT FENCE SHALL NOT BE PLACED IN ANY AREA OF CONCENTRATED FLOW NOR IN AREAS WHERE ROCK OR ROCKY SOILS PREVENT THE FULL AND UNIFORM ANCHORING OF THE FENCE TOE.
3. THE CONTRACTOR SHALL INSPECT THE SILT FENCE AFTER EVERY PRECIPITATION EVENT AND IMMEDIATELY REPAIR ANY DEFICIENCIES.
4. THE CONTRACTOR SHALL REMOVE ACCUMULATED SEDIMENTS AS REQUIRED TO KEEP THE FENCE FUNCTIONAL. IN ALL CASES, THE CONTRACTOR SHALL REMOVE DEPOSITS WHERE ACCUMULATIONS REACH ONE-HALF THE ABOVE GROUND HEIGHT OF THE FENCE.
5. THE CONTRACTOR SHALL IMMEDIATELY REPAIR ALL UNDERCUTTING OR EROSION OF THE ANCHOR TOE WITH A ROCK FILTER OUTLET.
6. THE CONTRACTOR SHALL CONFORM TO ANY RECOMMENDATIONS BY THE MANUFACTURER FOR REPLACING FILTER FABRIC FENCE DUE TO WEATHERING.

Fabric Formed Concrete Mats - Technical Specification and Optional Features/Accessories

1.0 Scope of Work

The intent of this specification is to define the material and installation requirements for fabric formed concrete mats installed in accordance with the Design Drawings, technical data and as specified herein.

1.1 Work Included

The work shall include, but not be limited to, the following items as indicated:

A. Preparation and grading of surfaces to receive fabric mats.

B. Placing fabric mats and filling them with a pumpable sand/cement slurry to form a stable erosion protection system.

C. Offsite disposal of excess or unsuitable materials and debris.

2.0 Codes and Standards

A. Standards, specifications, manuals, codes and other publications of nationally recognized organizations and associations are referenced herein. Methods, equipment and materials specified herein shall comply with the specified and applicable portions of the referenced documents, in addition to federal, state or local codes having jurisdiction.

B. References to these documents are to the latest issue date of each document, unless otherwise indicated, together with the latest additions, addenda, amendments, supplements, etc., thereto, in effect as of the date of contract for the work.

C. Abbreviations listed indicate the form used to identify the reference documents in the specification text.

2.1 ASTM – American Society for Testing and Materials

A. ASTM C 31 – Standard Practice for Making and Curing Concrete Test Specimens in the Field.

B. ASTM C 39 – Standard Test Method for Compressive Strength of Cylindrical Concrete Specimens.

C. ASTM C 143 – Standard Test Method for Slump of Hydraulic Cement Concrete.

D. ASTM C 172 – Standard Practice for Sampling Freshly Mixed Concrete.

E. ASTM C 173 – Standard Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

F. ASTM C 231 – Standard Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method.

G. ASTM C1064 – Standard Test Method for Temperature of Freshly Mixed Portland-Cement Concrete.

H. ASTM D 543 – Standard Practices for Evaluating the Resistance of Plastics to Chemical Reagents.

I. ASTM D 751 – Standard Test Methods for Coated Fabrics.

J. ASTM D 792 – Standard Test Methods for Density and Specific Gravity (Relative Density) of Plastics by Displacement.

K. ASTM D1777 – Standard Test Method for Thickness of Textile Materials.

L. ASTM D2101 – Standard Test Method for Tensile Properties of Single Man-Made Textile Fibers Taken From Yarns and Tows.

M. ASTM D3776 – Standard Test Methods for Mass Per Unit Area (Weight) of Fabric.

N. ASTM D3786 – Standard Test Method for Hydraulic Bursting Strength of Knitted Goods and Nonwoven Fabrics (Mullen Burst).

O. ASTM D3787 – Standard Test Method for Bursting Strength of Knitted Goods: Constant-Rate-of Traverse (CRT) Ball Burst Test.

P. ASTM D3885 – Standard Test Method for Abrasion Resistance of Textile Fabrics.

Q. ASTM D4355 – Standard Test Methods for Deterioration of Geotextiles by Exposure to Light, Moisture and Heat in a Xenon Arc Type Apparatus.

R. ASTM D4491 – Standard Test Methods for Water Permeability of Geotextiles by Permittivity.

S. ASTM D4533 – Standard Test Method for Trapezoid Tearing Strength of Geotextiles.

T. ASTM D4632 – Standard Test Method for Grab Breaking Load and Elongation of Geotextiles.

U. ASTM D5034 – Standard Test Method for Breaking Strength and Elongation of Textile Fabrics (Grab Test).

V. ASTM D5035 – Standard Test Method for Breaking Strength and Elongation of Textile Fabrics (Strip Method).

3.0
Supplier's Drawings and Data Submittals

A. Supplier shall submit drawings and data as specified. Supplier's drawings and data shall be submitted via electronic medium in a format compatible for importing into the Buyer's information systems specified by the Buyer.

3.1
Submittals Prior to Installation

The Supplier shall submit the following items at least 30 days prior to scheduled delivery of materials:

A. Manufacturer's literature providing specifications on the fabric mats that will be supplied.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

B. Manufacturer's certification that the fabric mats to be supplied comply with the requirements of this Technical Specification.

C. Manufacturer's Quality Control and Construction Quality Control Plans. The MQC Plan shall state the frequency that index tests are performed on the fabric mat during manufacturing.

D. If requested by the Buyer, four samples of each fabric mat suitable for testing.

E. Required concrete grout slurry mix design, including requirements for compressive strength, slump, air content and maximum temperature.

3.2
Submittals During and After Installation

The Supplier shall submit the following items on a daily basis during installation and a complete set of data within 30 days of the completion of the work:

A. Results of tests performed on the concrete grout fill.

4.0
Construction Quality Assurance

A. The Supplier shall examine the areas and conditions under which the work is to be installed and notify Buyer in writing of conditions detrimental to the proper and timely completion of the work that have changed from the time of the bidder's walkdown.

B. Material and installation procedures are subject to inspection and tests conducted by an Independent Testing Service employed by the Buyer. Such inspections and tests will not relieve the Supplier of responsibility for providing material and installation procedures in compliance with specified requirements. The Buyer reserves the right, at any time before final acceptance, to reject material not complying with the specified requirements.

C. The Supplier shall correct deficiencies in the work which inspections and laboratory test reports have indicated to be not in compliance with requirements. The Supplier shall perform additional tests, at his expense, as may be necessary to reconfirm any noncompliance of the original work, and as may be necessary to show compliance of corrected work.

D. The Supplier shall promptly correct errors or flaws in material or placement of the protection mats identified during construction. The Supplier shall make immediate substitution of non-complying component or make field changes to make the non-complying component acceptable. Whether the correction is made by substitution or field correction, it shall be performed without cost to the Buyer.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

4.1
Testing

4.1.1
Independent Testing Service

An Independent Testing Service shall perform the following:

A. Test material for the concrete slurry fill and prepare initial test cylinders in accordance with the requirements specified herein.

B. Prepare test cylinders and determine the compressive strength of job concrete fill test cylinders.

4.1.2
Concrete Grout Testing

A. Obtaining and testing concrete grout shall be by the Independent Testing Service in accordance with the following specifications:

- Sampling freshly mixed grout shall be done in accordance with ASTM C172.
- Making and curing concrete test specimens shall be in accordance with ASTM C31.
- Slump test shall be in accordance with ASTM C143.
- Air Content tests shall be in accordance with ASTM C173 or ASTM C231.
- Tests for the temperature of the freshly mixed grout shall be in accordance with ASTM C1064.
- Compressive strength test shall be in accordance with ASTM C39.

B. The frequency of testing shall be as directed by Buyer as follows:

- At least one test shall be made for each day's placement of grout, but not less than once for each 100 cubic yards or part thereof placed.
- A test shall consist of a minimum of four cylinders taken from the same truck. One 7-day and two 28-day tests shall be performed by the laboratory with results submitted to the Buyer as soon as possible. One spare cylinder shall be made and used as directed by the Buyer.
- A slump test and air content test shall be performed on every 100 cubic yards of concrete grout.
- The temperature of each 100 cubic yards shall be recorded in the field prior to placement. If the concrete grout temperature is in excess of 100°F, the concrete shall be rejected.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

5.0
Materials

5.1
Fabric Design

A. Fabric-forming material shall consist of double-layer, open-selvage fabric joined in a mat configuration. The fabric shall be woven of 100% continuous multi-filament nylon fiber of which 50% by weight shall be bulk textured fiber. The use of staple yarns will not be permitted.

B. The fabric shall be woven in such a manner as to provide interwoven points of attachment on spaced centers. These points of attachment shall serve to control the thickness of the finished product and to also act as a filter point to provide relief of hydrostatic uplift pressure beneath the completed revetment. The fabric shall be woven in a basket or other open pattern to provide permeability at the filter points and the main fabric field.

C. The spacing of the filter points is indicated on the Design Drawings. This spacing will result in an average revetment thickness that is consistent with the average thickness published by the manufacturer for the designated style specified.

5.2
Fiber and Fabric Material

A. The warp fiber shall be 1260 Denier Nylon, 18.5 ends/inch per single layer and the fill fiber shall be 1900 Denier Nylon, 14 picks/inch per single layer. The fiber and fabric material shall meet the minimum requirements listed in Table 1.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

TABLE 1
MATERIAL PROPERTIES

PROPERTY	ASTM TEST METHOD	MINIMUM TEST VALUE
Fiber count	-	0.164 g/m
Trapezoidal tear breaking force on the warp fiber at 70% elongation	D 4533	80 lbs/in
Trapezoidal tear breaking force on the fill fiber at 70% elongation	D 4533	40 lbs/in
Density	D 792	1.00 g/cm^3
Fiber dry breaking strength at 48% elongation	D 2101	20 lbs
Fiber wet breaking strength at 53% elongation (soaked in water for 2 hours)	D 2101	19 lbs
Tensile strength in the warp direction after exposure to 300 hours of Ca (OH) at a pH of 10	D 543	180 lbs/in
Tensile strength in the warp direction after exposure to 300 hours of H_2SO_4	D 543	170 lbs/in
Tensile breaking strength in the warp direction on a strip of the fabric at 39% elongation (1)	D 5034, D 5035	160 lbs/in
Tensile breaking strength in the fill direction on a strip of the fabric at 34% elongation (1)	D 5034, D 5035	190 lbs/in
Mass/unit area for a single layer of fabric	D 3776	7.8 oz/sq yd
Thickness of a single layer of fabric	D 1777	31 mils
Falling head permittivity of two layers of fabric woven together	D 4491	0.28 s^{-1} 0.04 cm/s (3)
Falling head permittivity of a single layer of fabric	D 4491	1.3 s^{-1} 0.12 cm/s
Seam strength (2)	D 751	35 lbs/in
Abrasion resistance in the warp direction	D 3885	160 lbs/in
Grab strength in the warp direction at 31% elongation	D 4632	350 lbs
Grab strength in the fill direction at 41% elongation	D 4632	275 lbs
Breaking strength in the warp direction after exposure to 500 hours of UV light	D 4355	190 lbs/in
Mullen burst test	D 3786	750 psi
Puncture test	D 3787	80 lbs

Notes for Table 1:

(1) 3" x 8" sample gripped along full width of the specimen with 3" of separation between grips. Strip test to be performed on single layer of fabric at cross-head speed of 5 inches per minute.

(2) Seam centered between grips 3" apart and gripped the full width of the specimen.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

(3) Applies to Filter Points only

5.3
Fabric Assembly

A. Adjacent fabric panels shall be connected by sewing or by means of zipper.

B. The two top layers of fabric and the two bottom layers of fabric shall be joined separately permitting full mat thickness between the two parallel seams. A single seam in which all four layers of the fabric are joined at one point will not be permitted.

C. If required, grout stops may be installed parallel to and in between individual mill widths at predetermined intervals to regulate the flow of the concrete fill. Grout stops shall be so designed as to produce full mat thickness along the full length of the grout stop.

5.4
Concrete Grout

A. The concrete grout shall consist of a mixture of Portland cement, fine aggregate and water so proportioned and mixed as to provide a readily pumpable slurry.

B. Admixtures and/or a pozzolan may be used with the approval of the Buyer. The use of superplasticizers and/or silica fume require special precautions and the approval of the Buyer.

C. The hardened concrete shall exhibit a minimum compressive strength of 2,500 psi at 28 days when specimens are made and tested in accordance with the provisions of ASTM C 31 and ASTM C 39.

5.5
Acceptable Materials

The following companies manufacture products that meet the requirements of the specification:

A. Fabriform Filter Point Fabric as manufactured by Construction Techniques, Inc., Cleveland, Ohio, 440-572-8300.

B. Other approved by Buyer.

6.0
Execution

6.1
Acceptance and Storage at the Project Site

6.1.1
Handling of Rolls

A. The method of off-loading the fabric at the project site shall not cause any damage to the fabric, its core, nor its protective covering.

B. Any protective covering that is accidentally damaged or stripped off of a pallet or roll shall be immediately repaired or the pallet or roll shall be moved to an enclosed facility until the repair can be made.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

6.1.2
Storage at the Field Site

A. The Buyer shall provide on-site storage space in a location near where the fabric will be placed such that on-site transportation and handling are minimized. The Supplier shall be responsible for protecting the stored material from theft and vandalism.

B. Rolls or pallets of fabric shall be stored in such a manner that cores are not crushed, the fabric damaged, and as required to provide protection from exposure to ultraviolet light, inundation, mud, dirt, dust, puncture, cutting or any other damaging or deleterious condition.

C. Outdoor storage of rolls or pallets shall not exceed the manufacturer's recommendations or longer than six months, whichever is less.

6.2
Inspection upon Delivery

A. Upon delivery of the materials to the site, the Supplier shall conduct a visual inspection of all rolls of fabric for damage or defects. This inspection shall be done without unrolling any rolls unless damage to the inside of a roll is found or suspected.

B. Any damage or defects shall be noted and immediately reported to the Buyer, the manufacturer and the carrier that transported the material. Any roll, or portion thereof, which, in the judgement of the Buyer, is seriously damaged, shall be removed from the project site and replaced with complying material at no additional cost to the Buyer.

6.3
Fabric Placement

A. Prior to concrete injection, the fabric shall be positioned over a geotextile on the grade as indicated on the Design Drawings making appropriate allowances for contraction of the fabric mats as a result of injecting the concrete grout.

B. Anchoring of fabric shall be as shown on the Design Drawings.

C. Fabric panels may be factory assembled in predetermined sizes and joined together side-by-side at the project site by field sewing or by means of zipper closures attached to the upper and lower layers of the fabric. In no case will simple unattached butt joints between panels be allowed. Overlapping shall be allowed only if approved by the Buyer.

6.4
Concrete Injection

A. Following placement of the fabric mats the specified concrete grout shall be injected between the top and bottom layers of the fabric through small slits cut in the upper layer of the fabric. The injection pipe shall be wrapped tightly at the point of injection with a strip of burlap, or similar material, during pumping to seal the joint between the injection pipe and the slit. After pumping, the burlap shall be pushed into the slit as the injection pipe is withdrawn in order to minimize spillage of the concrete slurry onto the surface of the revetment.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2000 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

B. The sequence of concrete slurry injection shall be such as to insure complete filling of the revetment-forming fabric to average thickness indicated by the manufacturer for the designated style specified on the Design Drawings.

C. Foot traffic will not be permitted on the freshly pumped mat since such traffic will cause permanent indentations in the mat surface. Walk boards shall be used where necessary.

D. Excess concrete slurry which has been inadvertently spilled on the mat surface shall be cleaned up with a broom and shovel. The use of a water hose to remove spillage from the surface of a freshly pumped mat will not be permitted.

E. During concrete slurry injection, the mat thickness shall be measured by inserting a short piece of stiff wire through the crowns of the mats midway between the filter points at several locations from the crest to the toe of the slope. Any mat measurements less than 90% of the average of all thickness measurements shall be re-injected until the average thickness indicated for the style specified has been attained.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their contractors, subcontractors, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Temporary and Permanent Seeding (Illinois) – Technical Specification and Optional Features/Accessories

1.0 Scope of Work

The intent of this specification is to define the minimum requirements for material and work for establishing a vegetative cover by planting grass seed.

1.1 Purpose and Use

A. All graded areas, slopes, and ditches which will not be paved or otherwise surfaced shall be provided with permanent seeding.

B. Graded areas subject to erosion shall not remain unprotected for longer than 30 days. Temporary seeding shall be provided by the Supplier to protect graded areas from erosion where permanent protection is not scheduled to be installed for 2 to 12 months after grading is completed.

1.2 Method of Seed and Mulch Application

Seed may be spread by a conventional method of application such as broadcasting, grass drill, or cultipacker followed by an application of mulch or by a hydro seeding procedure consisting of spraying a slurry mixture of water, seed, mulch, fertilizer, and tackifier onto the prepared seedbed.

1.3 Work Included

A. Furnish all materials.

B. Subgrade preparation.

C. Seedbed preparation, including placing topsoil and the addition of lime and fertilizer.

D. Seeding using broadcast, grass drill, or the cultipacker method and mulching, or hydro seeding with a mixture that contains seed, mulch and a tackifier.

E. Installation of matting where specified for erosion control.

F. Protection.

G. Maintenance.

H. Repairing and reseeding.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

2.0
Codes and Standards

A. Standards, specifications, manuals, codes and other publications of nationally recognized organizations and associations are referenced herein. Methods, equipment and materials specified herein shall comply with the specified and applicable portions of the referenced documents, in addition to federal, state or local codes having jurisdiction.

B. References to these documents are to the latest issue date of each document, unless otherwise indicated, together with the latest additions, addenda, amendments, supplements, etc., thereto, in effect as of the date of Contract for the Work.

C. Abbreviations listed indicate the form used to identify the reference documents in the Specification text.

2.1
USDA - United States Department of Agriculture, Soil Conservation Service

A. USDA-SCS Soil Classification Supplement to Soil Classification System (7th Approximation), SCS, USDA, Second Printing, March 1967.

2.2
ASTM - American Society for Testing and Materials

A. C602 - Specification for Agricultural Liming Materials.

B. D977 - Specification for Emulsified Asphalt.

C. D2026 - Specification for Cutback Asphalt (Slow-Curing Type).

D. D2027 - Specification for Cutback Asphalt (Medium-Curing Type).

E. D2028 - Specification for Cutback Asphalt (Rapid-Curing Type).

F. D2397 - Specification for Cationic Emulsified Asphalt.

G. D5268 - Specification for Topsoil Used for Landscaping Purposes.

3.0
Supplier's Drawings and Data Submittals

Supplier shall submit drawings and data not less than 30 days before material is to be delivered. Supplier's drawings and data shall be submitted via electronic medium in a format compatible for importing into the Buyer's information systems specified by the Buyer.

3.1
Topsoil

A. Topsoil Material:

- A copy of laboratory reports on two representative samples of topsoil. Laboratory tests shall be performed for:
- Percent deleterious material.
- Total organic content.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

- Silt and clay contents.
- Sand content.
- pH.

B. If it is anticipated that topsoil stripped from either the present site or the borrow area will be used for permanent seeding, if requested by the Buyer, the Supplier shall provide two 50-pound samples to the Buyer's Testing Service for analyses.

3.2 Seed

A. A certified copy of a statement signed by the seed supplier that each lot of seed has been tested by a recognized seed-testing laboratory within six months before the date of delivery to the plant site.

B. A certified statement signed by the seed supplier that the maximum percentage of noxious weeds in the seed mixture complies with state law.

3.3 Data on Materials as Applied

As applied data on the following items:

A. Seed mixture and seed application rate.

B. Limestone application rate.

C. Fertilizer type, trademark name (if any), chemical composition, and application rate.

D. Mulch.

E. Tackifier.

3.4 Binder Spray

Data on the binder spray (tackifier) to be used on straw mulch or with hydro seeding. If a synthetic binder (tackifier) will be used, the Supplier shall provide a complete set of Manufacturer's specifications at least 30 days prior to anticipated use. Manufacturer's specifications shall contain a description of the binder material, the recommended method of application, and the recommended application rate.

3.5 Matting

Catalog data on the proposed erosion control matting and Manufacturer's literature on the recommended method of installation.

3.6 Samples

If requested by the Buyer, submit a sample of each material designated by the Buyer for laboratory testing.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

4.0 Products

4.1 Topsoil

A. Topsoil shall consist of sandy clay loam, sandy loam, loam, clay loam, silty clay loam or silt loam as defined by the SCS Soil Classification System.

B. Topsoil shall be relatively free from large roots, sticks, weeds, brush or stones larger than 1 inch in diameter or other litter and waste products. It shall have at least 90 percent passing the No. 10 sieve.

C. The topsoil shall meet requirements of ASTM D5268 as follows:

- It shall contain not less than 2 percent nor more than 20 percent total organic matter.
- It shall contain not less than 35 percent nor more than 70 percent silt and clay.
- It shall contain not less than 20 percent nor more than 60 percent sand.
- The pH of the sample shall not be lower than 5.0 nor higher than 7.5.
- The percent deleterious material (rock, gravel, slag, cinder, roots, sod) shall not exceed 5 percent.

4.2 Seed

4.2.1 General Requirements

A. Grasses, legumes, or cover crop seed of the type specified herein shall conform to the standards of the United States Department of Agriculture for seed certification.

B. Seed or seeding mixtures shall be furnished in sealed bags or containers in accordance with standard commercial practice.

C. Each bag or container shall be tagged or labeled in accordance with state law. As a minimum, the tag or label shall provide the following information:

- Name and address of the supplier.
- Common name of seed.
- Lot number.
- Net weight.
- Guaranteed percentage of germination.
- Percentage of weed seed and inert material content.

D. Seed which has become wet, moldy, or otherwise damaged in transit or storage will not be accepted.

E. All seed furnished shall be free of primary noxious weed seed such as Russian or Canadian Thistle, European Birdweed, Johnson Grass and Leafy Spurge. The maximum allowable percentage of noxious weed seed in the seed mixture shall comply with state law.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

4.2.2
Seed Storage

If it is necessary to store seeds after their arrival on the site, they shall be stored in an approved weatherproof building in such a manner as to protect the seeds from deterioration and to permit easy access for inspection. The Buyer's approval for the storage building and the method of storage shall not relieve the Supplier of responsibility for the quality and fitness of the seeds at the time of their use.

4.2.3
Seed Mixture

A. Seed species, rate per acre, and other data relevant to permanent seeding are given in Table 1.

B. Seed species, rate per acre, and other data relevant to temporary seeding are given in Table 2.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

TABLE 1
ACCEPTABLE MIXTURES FOR PERMANENT SEEDING

Mixture	Seed Species (1)	Seeding Rate, Pure Live Seed for Conventional Seed Application (2)		Suitable pH	Site Suitability			Acceptable Dates for Seeding
		Lbs. per acre	Lbs. per 1,000 sq. ft.		Sunny, Dry	Well Drained	Wet	
1	Smooth Bromegrass or Tall Fescue	30	0.75	6.0-7.5	X	X	X	4-1 to 6-1 8-1 to 9-1
	Alfalfa or Birdsfoot Trefoil	10	0.25					
2	Smooth Bromegrass or Tall Fescue	30	0.75	6.0-8.0	X	X		4-1 to 6-1 8-1 to 9-1
	Crown Vetch	20	0.50					
3	Tall Fescue	15	0.35	5.5-7.5		X	X	4-1 to 6-1 8-1 to 9-1
	Timothy or Redtop	3	0.07					
	Birdsfoot Trefoil	15	0.35					
4	Reed Canary Grass	15	0.35	5.5-7.5	X	X		4-1 to 6-1 8-1 to 9-1
	Smooth Bromegrass or Tall Fescue	15	0.35					
	Ladino (optional)	3	0.07					

Notes: (1) Mixtures as defined by SCS for Illinois.

(2) Triple the seeding rate shown in the table when hydro seeding.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. TABLE 2
ACCEPTABLE MIXTURES FOR TEMPORARY SEEDING

MIXTURE	SEED SPECIES	MAXIMUM WEED SEED (percentage)	SEEDING RATE PER ACRE	SUITABLE pH	PLANTING DEPTH	ACCEPTABLE DATES FOR SEEDING
1	Wheat	0.50	150 lbs	5.5 to 7.0	1" to 1 ½"	3-1 to 5-15 7-1 to 10-15
2	Cereal Rye	0.50	150 lbs	5.5 to7.0	1" to 1 ½"	3-1 to 5-15 7-1 to 10-15
3	Spring Oats	0.50	100 lbs	5.5 to 7.0	1"	3-1 to 7-1
4	Perennial Ryegrass	0.50	40 lbs	5.0 to 7.5	1/4"	4-1 to 6-1 8-1 to 9-15

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

4.3
Lime (Agricultural Ground Limestone)

Agricultural lime shall be flour grade meeting the requirements of ASTM C602.

4.4
Fertilizer

A. Fertilizer shall be a standard brand commercial grade of inorganic fertilizer furnished in unopened containers. The material may be separate or in a mixture containing the percentage of total nitrogen, available phosphoric acid and water-soluble potash in the amounts specified. If materials are separate, the Buyer shall be present when the separate fertilizers are mixed in the field. The fertilizer shall be odor free.

B. Fertilizer shall be supplied in one of the following forms:

- A dry free-flowing granular fertilizer suitable for application by an agricultural fertilizer spreader.
- A soluble form that will permit complete suspension of insoluble particles in water, suitable for application by power sprayer.

C. The following information shall be shown on the fertilizer container or on a tag attached thereto:

- Name and address of manufacturer.
- Name, brand or trademark.
- Number of net pounds of ready-mixed material in the package.
- Chemical composition or analysis.
- Guarantee of analysis.

4.5
Mulch

4.5.1
Straw Mulch

A. Straw shall be stalks of small grain straw of wheat, rye, oats, barley or other approved grain. Straw shall be air dried and free of grain and noxious weed seed, other materials detrimental to plant life, and mold.

B. Straw shall be seasoned before bailing or loading. Straw mulch shall be suitable for spreading with mulch blower equipment.

C. Old dry straw which breaks up in the crimping process instead of bending, or straw in such advanced stages of decomposition that it will smother or retard the normal growth of grass, is not acceptable.

4.5.2
Wood Cellulose Fiber Mulch

A. Wood cellulose fiber shall be partly digested wood fibers.

B. The material shall be dyed green.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

C. The material shall not contain growth or organism inhibiting agents.

D. The material shall be air-dried with a minimum of 30 percent of the fibers 3.7 mm (0.145 inch) or longer.

4.5.3
Binder Sprays

A. Cutback Asphalt shall be in accordance with ASTM D2026 (Slow-Curing Type), ASTM D2027 (Medium-Curing Type) or ASTM D2028 (Rapid-Curing Type).

B. Emulsified Asphalt shall be in accordance with D977 (Emulsified Asphalt) or D2397 (Cationic Emulsified Asphalt).

4.6
Tackifier (Synthetic Binder)

A. Tackifier material shall be an acrylic copolymer or a polyvinyl acetate emulsion in a liquid form. The material may contain additives to enhance its ability to penetrate the soil.

B. The material shall be non-toxic, non-flammable, and biodegradable.

C. Approved Materials:

- Soil Seal Concentrate manufactured by Soil Seal Corp., 1111 W. Sixth St., Los Angeles, California 90017, telephone number 213-481-7185.
- Reinco Mulch Binder and Terra Tac manufactured by Rienco Mulch Binder Corp., 520 North Avenue, Plainfield, New Jersey 07060, telephone number 1-800-526-7687.
- Aerospray 70 Binder manufactured by American Cyanamid Company, Mobile, Alabama 36601, telephone number 205-476-5800.

4.7
Inoculant

A. The inoculant for treating legume seeds shall be a pure culture of nitrogen fixing bacteria prepared specifically for the species and shall not be used later than the date indicated on the container. A mixing medium, as recommended by the manufacturer, shall be used to bond the inoculant to the seed.

B. All legumes not pre-inoculated shall be inoculated within 12 hours of seeding. If the seed was pre-inoculated more than 60 days prior to seeding then it must be reinoculated.

4.8
Matting for Erosion Control

A. Matting for erosion control may be one of the following unless a specific matting is specified on the Design Drawings.

- Jute mat shall be cloth of a uniform plain weave of undyed and unbleached single jute yarn, 48 inches in width, plus or minus 1 inch and weighing an average of 1.2 pounds per linear yard of cloth with a tolerance of plus or minus 5 percent, with approximately 78 warp ends per width of cloth and 41 weft ends per linear yard of cloth. The yarn shall be

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

of a loosely twisted construction having an average twist of not less than 1.6 turns per inch and shall not vary in thickness by more than one-half its nominal diameter.

- Excelsior mat shall be wood excelsior, 48 inches in width plus or minus 1 inch and weighing 0.8 pounds per square yard plus or minus 10 percent. The excelsior material shall be covered with a netting to facilitate handling and to increase strength.
- Glass fiber matting of bonded textile glass fibers with an average fiber diameter of 8 to 12 microns, 2 to 4 inch strands of fiber bonded with phenol formaldehyde resin. Mat shall be roll type, water permeable, minimum thickness 1/4 inch, maximum thickness 1/2 inch, density not less than 3 pounds per cubic foot.

B. Staples for anchoring soil stabilizing materials shall be No. 11 gauge wire or heavier. Their length shall be 6 to 10 inches. Ten inch long staples shall be used on loose, unstable soils.

5.0 Execution

5.1 Site Preparation

A. Prior to seeding, install all erosion control facilities specified on the Design Drawings. These include: diversions, berms, sediment control traps, silt fences and straw bale dikes.

B. Grade areas as specified on the Design Drawings. Gullied and uneven areas shall be smoothed before starting seedbed preparation.

5.2 Limestone for pH Adjustment

A. The Supplier shall apply limestone as required to raise the pH of the subsoil. Apply a minimum of 4 tons of limestone per acre for clayey soils, 3 tons of limestone per acre for sandy loam, and 2 tons of limestone per acre for loamy sand or silty soils.

B. Thoroughly work the limestone into the subsoil to a depth of 2 to 3 inches with a harrow or disk. The limestone may be applied prior to or concurrently with the fertilizer described.

5.3 Fertilizer

A. The Supplier shall apply a 12-12-12 fertilizer to the subsoil at a rate of 300 pounds per acre.

B. Work the fertilizer into the soil to a depth of 2 to 3 inches with a harrow, disk, or rake. On slopes, operate the disk or rake across the slope.

C. If hydro seeding is used, the fertilizer may be added to the hydroseed mixture.

5.4 Tilling of Subsoil

Prior to placing the topsoil, scarify the subsoil to a depth of 3 inches immediately prior to spreading topsoil to ensure bonding of the topsoil and the subsoil. Repeat scarification in areas where equipment used for hauling and spreading topsoil has compacted the subsoil.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

5.5
Placing Topsoil

Note: topsoil does not have to be placed for temporary seeding. Topsoil must be placed prior to permanent seeding.

A. Place topsoil during dry weather on a dry, unfrozen subgrade. Topsoil shall not be spread if it is frozen or muddy.

B. Remove large pieces of organic matter and foreign non-organic material from topsoil while spreading. There shall be no large roots, branches or trash of any kind in the topsoil.

C. Spread the topsoil to provide a compacted thickness of not less than 4 inches.

D. Compact the topsoil with a roller not exerting more than 100 pounds per square inch. The topsoil must be loose enough for water infiltration and root penetration. The soil surface on slopes shall be roughened to catch seeds if they are to be broadcast.

5.6
Seeding (Conventional Method)

A. Tables 1 and 2 list acceptable seed mixtures that may be used for seeding. The Supplier shall select a mixture from the appropriate table and plant within the dates shown in that table for that mixture.

B. Apply seed uniformly at the rate shown in the appropriate table with a rangeland grass drill or cultipacker type seeder, or broadcast seed uniformly. The seeding methods and equipment shall be submitted to the Buyer for approval prior to beginning work.

C. All seeders shall be calibrated and adjusted to sow seeds at the proper rate. Equipment shall be operated to ensure a complete and even coverage. Do not seed areas greater than that which can be mulched on the same day.

D. Do not sow immediately following a rain, where the ground is too dry, during windy periods, or otherwise when conditions are not proper for seeding.

E. No seeds shall be sown until the purity test has been completed for the seeds to be used and the tests show that the seed meets the noxious weed seed requirements.

F. Within 12 hours, all seeded areas shall be rolled at right angles to the runoff with a cultipacker or approved roller to compact the seedbed and place the seed in contact with the soil. The optimum depth for planting shall be 1/4 inch. Rolling is not required if the seeding equipment is equipped with a roller that achieves the desired compaction or a grass drill has been used. Note: For temporary seeding planted without topsoil, the optimum planting depth is shown in Table 2.

5.7
Mulching (Conventional Method)

5.7.1
Straw Mulching

A. All seeded areas shall be mulched with straw mulch within 24 hours after seeding. The mulch may be hand or machine applied. The mulch shall be uniformly applied in a loose enough condition to permit air to circulate, but compact enough to reduce erosion. About 25 percent of

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

the solid surface should show through the mulch. If baled mulch material is used, care shall be taken that the material is in a loosened condition and contains no lumps or knots of compacted material.

B. Straw mulch shall be applied at the rate of 2 tons per acre, or 75 to 100 (two bales) pounds per 1,000 square feet.

C. Straw mulch shall be anchored immediately after placement to minimize loss by wind or water. Straw mulch shall be anchored using a mulch anchoring tool or by spraying with a liquid binder.

5.7.2
Anchoring Mulch Using a Mulch Anchoring Tool

A. The mulch anchoring tool shall be designed to punch and anchor the mulch into the top 2 to 3 inches of soil at 6 inch intervals. As an alternative, a smooth disk set in a straight position may be used.

B. On slopes flatter than 3 horizontal to 1 vertical, mulch anchoring shall cross the contour of the land (across slopes). On slopes steeper than 3 horizontal to 1 vertical, the mulch shall be anchored by tracking a bulldozer with 1-1/2 inch track cleats up and down slope making grooves running across the slope.

5.7.3
Anchoring Using a Sprayed Liquid Binder

A. A sprayed liquid binder may be used in lieu of crimping to anchor the mulch. The binder may be sprayed into the mulch as it leaves the blower pipe or it may be applied as an over spray. If over sprayed, the binder spray should be heavier at the edges where wind catches the mulch, in valleys and at crests of banks. Binder shall be applied uniformly over the remainder of the area. Caution shall be used when spraying binder near areas occupied by construction personnel.

B. Binder Spray shall be applied at the following rates:

- Cutback asphalt - Rapid curing (RC-70, RC-250, and RC-800) or medium curing (MC-250 or MC-800). Apply 5 gallons per 1,000 square feet or 218 gallons per acre.
- Emulsified asphalt - (SS-1, CSS-l, CMS-2, MS, RS-l, RS-2, CRS-l, and CRS-2). Apply 5 gallons per 1,000 square feet or 218 gallons per acre.
- Synthetic binders - Synthetic binders such as Acrylic Dir (Agri-Tac), DCA-70, Petroset or Terra Tack may be used at rates recommended by the manufacturer to anchor mulch material.

5.7.4
Repairing and Reseeding

A. Areas not mulched and anchored within 24 hours after seeding shall be reseeded and mulched.

B. Areas not properly mulched, or damaged due to construction activities, shall be repaired, reseeded, and remulched.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

5.8
Hydro Seeding

A. Hydro seeding consists of spraying a slurry mixture of water, seed, fertilizer, mulch, and a tackifier on a prepared seed bed.

B. The slurry mixture shall be mixed and applied using a hydraulic seeder. Hydraulic seeding equipment shall include a pump rated and operated at not less than 100 gallons per minute and 100 psi pressure. The tank shall have a mechanical agitator powerful enough to keep the slurry mixture in a uniform suspension in water.

C. Hydrated lime **shall not** be added to the slurry mixture.

D. The slurry mixture shall contain a maximum of 55 percent solids (125 pounds of solids per 100 gallons of water).

E. The seed mixture shall be as specified in Table 1 or Table 2 except that the weight of seed in the slurry mixture shall be a minimum of three times the weight of pure live seed per acre specified in the appropriate table for conventional seed application.

F. The slurry mixture shall contain a minimum of 1500 pounds of wood cellulose fiber mulch per acre or 2000 pounds of straw mulch per acre.

G. The amount of tackifier provided per acre shall be in accordance with Manufacturer's recommendations.

H. The slurry-mixture shall contain a minimum of 1000 pounds of grade 12-12-12 fertilizer per acre or the equivalent weight of chemicals if another grade is used.

I. The soil surface shall be moist when the slurry mixture is applied.

5.9
Laying and Securing Matting

5.9.1
Laying and Securing Jute Matting

A. Prepare the seed bed as specified and lime, fertilize, and seed, except that when using jute matting, apply approximately one-half of the seed after laying the mat.

B. Most drainage channels will require multiple widths of jute matting. The total width shall be as specified on the Design Drawings. Unroll matting starting at the upper end of the channel allowing a 4 inch overlap of mattings along center of channel.

C. Bury the top ends of jute matting in a narrow trench. Backfill the trench and tamp firmly to conform to channel cross-section. Secure the matting with a row of staples about 4 inches down slope from the trench. Spacing between staples shall be a maximum of 6 inches.

D. Staple the 4 inch overlap in the center of the channel using an 18 inch spacing between staples. Before stapling the outer edges of the matting, make sure the matting is smooth and in firm contact with the soil. Staples shall be placed 2 feet apart along the outer edge of matting.

E. Where one roll of jute matting ends and another begins, the end of the top strip shall overlap the upper end of the lower strip by 4 inches, shiplap fashion.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). It was prepared by S&L for use by S&L, its clients, their Suppliers, subSuppliers, and bidders on projects where S&L provides engineering services and shall not otherwise be reproduced in whole or in part or released to any third party without the prior written consent of S&L. Copyright Sargent & Lundy 2001 all rights reserved. Specifications located in the Document Management System are to be considered as the official version of the Specification.

F. Where matting crosses erosion stops, reinforce with a double row of staples placed six (6) inches apart in a staggered pattern on either side of erosion stop. Likewise, overlaps joining the length of matting together and the discharge end of the matting liner should be similarly secured with 2 double rows of staples.

5.9.2
Laying and Securing Excelsior Matting

A. Provide the same seedbed preparation as specified for jute matting with the exception that all seeding must be completed before laying excelsior matting.

B. Bury the top ends of excelsior matting in a trench as described for jute matting. As the blankets are unrolled down slope, the matting must be on top with the wood fibers in contact with the soils. Butt snugly at the ends and sides before stapling.

C. Using two (2) foot spacing between staples, excelsior matting shall be secured with four rows for each strip, with one row along each edge and alternating parallel rows down the center. The stapling over erosion stops, entrance and discharge ends of matting and butted end joints shall be the same as described for jute matting.

5.10
Construction Completed after Acceptable Seeding Dates

When construction is completed between October 15 and March 1 prepare the seedbed, fertilize and mulch as specified. Apply seed for permanent seed sometime between December 1 and March 1 increasing the seeding rates shown in Table 1 by 50 percent.

6.0
Protection

Planted areas shall be protected from damage and erosion. The Supplier shall provide and erect temporary barriers and signs as necessary to prevent vehicles, equipment and foot traffic from damaging seeded areas.

7.0
Maintenance

The Supplier shall perform the following maintenance tasks:

A. Keep seedbed continually moist with light, frequent sprinklings several times a day to prevent seedlings from drying out.

B. Inspect periodically after planting to see that vegetative stands are adequately established. Immediately reseed areas which show bare spots larger than 2 feet by 2 feet after germination.

C. Check for erosion damage after storm events and repair damage. Reseed and mulch, if necessary.

D. Fertilize newly permanent seeded areas one year after seeding with 300 pounds per acre of a complete (N-P-K) 10-10-10 or equivalent turf type slow release fertilizer.

- Application rate per acre shall be:

  Nitrogen (N) - 120 pounds of actual nitrogen.

This document contains information which is confidential and proprietary to Sargent & Lundy (S&L). Phosphorus (P) - 120 pounds of P_2O_5.

Potassium (K) - 120 pounds of K_2O.

3.5.1	Weekly Inspections	3
3.5.2	Quarterly Inspections	3
3.5.3	Five-year Inspections	
4.0	INSPECTION CHECKLISTS	3

1.0 GENERAL

The following operations and maintenance procedures are provided to maintain the structural integrity of the west ash storage surface impoundment at the Hennepin Power Station, which is unclassified and unpermitted, by the Illinois Department of Natural Resources, Office of Water Resources.

2.0 EMERGENCY OPERATIONS

2.1 Unusual Conditions

Any unusual condition discovered during major storm events or routine inspection, which may constitute an emergency, shall be handled as follows. Notice of any type of emergency involving the dikes or outfall shall be made to the Shift Leader on duty [(815) 339-9211]. The Shift Leader on duty shall notify the Station Manager, Ted Lindenbusch [home: (815) 875-2381], or, in his absence, the Environmental Coordinator, John P. Augspols [home: (815) 925-7488]. One of the above designated personnel shall notify the following city, county, state and federal regulatory authorities of the emergency condition.

- Division of Water Resources, Dam Safety Section, Dam Safety Engineers (217) 782-3862
- Illinois Emergency Management Agency, 24-hour service 1-(800) 782-7860
- Putnam County Sheriff/Hennepin Police Department (815) 925-7015
- Senior Director – Environmental Compliance, Dynegy Operating Company (618) 206-5912

2.2 Dewatering

The Station Manager or the Environmental Coordinator shall have the responsibility of determining how repairs shall be accomplished and whether dewatering of the disposal facility is necessary. Emergency dewatering shall be accomplished by portable pumps.

3.0 MAINTENANCE

3.1 Vegetation

Dikes shall be maintained to protect the structural integrity of the disposal facility. Damaged and barren areas shall be repaired as soon as appropriate after being discovered. Damaged areas shall be filled with topsoil. Limed, fertilized, and seeded with appropriate vegetation. Trees and shrubs observed during semiannual inspections shall be cut and removed from the dikes and discharge channel. This shall be done as frequently as is necessary to insure that no tree reaches a size where the root structure would require removal and filling. Woody vegetation, shrubs, and trees shall be removed during the early stages of growth before reaching a three-inch diameter.

Low growing vegetation, a prairie grass mixture that grows to a height of no more than six inches, shall be planted and maintained to facilitate inspections.

3.2 Discharge Structure

The discharge structure shall be inspected periodically for significant corrosion and deterioriation. Any defects discovered shall be promptly repaired.

3.3 Animal Damage and Repairs

Animal burrows discovered during inspections shall be promptly repaired by filling with grout.

3.4 Restriction of Unauthorized Vehicles

Facility approaches shall be posted with signs restricting unauthorized travel on the roadways and slopes.

3.5 Inspections/Remedial Measures

3.5.1 Weekly Inspections

Weekly inspections of the perimeter berms shall be conducted, looking for seepage and slumping, and unusual seepage at and/or blockage of the outfall structures in each cell. All findings shall be entered into the weekly inspection checklist, discussed in Section 4.0. Maintenance activities shall be initiated, if required. Refer to Section 4.0 for the recommended inspection checklist to be used for the weekly inspections.

3.5.2 Quarterly Inspections

Inspections shall be made quarterly by Station personnel to determine the general condition of the dam and embankments. During these inspections, embankment erosion, tree growth, and embankment seepage shall be monitored. Seepage shall be observed for change in quantity and coloration. Refer to Section 4.0, for the recommended inspection checklist to be used for documenting the quarterly inspections.

3.5.3 Annual Inspections

An annual inspection shall be made by a licensed professional engineer. This inspection shall follow the Illinois Department of natural Resources (IDNR) *Guidelines and Forms for Inspection of Illinois Dams*, and shall be followed by verbal and written reports by the consulting engineer. Based on the findings of the inspection, the Station Manager shall implement corrective action as required to promote dam safety. Procedures and methods for corrective action shall be performed in accordance with recommendations of the consulting engineer and as outlined above. Because the dam is not permitted by the IDNR, copies of the engineer's report, along with corrective action taken, will not be reported to the IDNR.

4.0 INSPECTION CHECKLISTS

The following Inspection checklists should be used during the weekly and quarterly inspections.

WEEKLY DAM INSPECTION FORM

Dam Location: Hennepin Power Station – West Ash Pond
Owner: Dynegy Midwest Generation, LLC, Havana Power Station
Permit No.:Not permitted **Class of Dam: Not classified**
Type of Dam: Homogeneous earth dam
Type of Spillway: Drop structure

Date Inspected: _____
Weather Conditions: _____
Pool Elevation: _____

Inspection Personnel:

_____ _____
Name / Title **Signature**

Inspection Item	Conditions	Location of Problem and Recommended Remedial Measures and Implementation Schedule
Vertical and Horizontal Alignment of Crest		
Unusual Movement or Cracking at or Beyond Toe

1.0 GENERAL

The following operations and maintenance procedures are provided to maintain the structural integrity of the old east ash storage surface impoundment at the Hennepin Power Station, which is unclassified and unpermitted, by the Illinois Department of Natural Resources, Office of Water Resources.

This is primarily the @ 0.5 mile significant berm system that extends along the Illinois River. The old east ash pond system consists of the inactive cells # 2 and # 4. As a result of the May 2011 USEPA dam assessment, a dam safety permit was submitted to IDNR in May 2013, to address major modifications to this significant berm. These major modifications include extensive tree removal and resloping. Resloping is required to improve slope stability and allow safe access to slope, for long-term mowing and maintenance.

2.0 EMERGENCY OPERATIONS

2.1 Unusual Conditions

Any unusual condition discovered during major storm events or routine inspection, which may constitute an emergency, shall be handled as follows. Notice of any type of emergency involving the dikes or outfall shall be made to the Shift Leader on duty [(815) 339-9211]. The Shift Leader on duty shall notify the Station Manager, Ted Lindenbusch [home: (815) 875-2381], or, in his absence, the Environmental Coordinator, John P. Augspols [home: (815) 925-7488]. One of the above designated personnel shall notify the following city, county, state and federal regulatory authorities of the emergency condition.

- Division of Water Resources, Dam Safety Section, Dam Safety Engineers (217) 782-3862
- Illinois Emergency Management Agency, 24-hour service 1-(800) 782-7860
- Putnam County Sheriff/Hennepin Police Department (815) 925-7015
- Senior Director – Environmental Compliance, Dynegy Operating Company (618) 206-5912

2.2 Dewatering

Not applicable.

3.0 MAINTENANCE

3.1 Vegetation

Dikes shall be maintained to protect the structural integrity of the disposal facility. Damaged and barren areas shall be repaired as soon as appropriate after being discovered. Damaged areas shall be filled with topsoil. Limed, fertilized, and seeded with appropriate vegetation. Trees and shrubs observed during semiannual inspections shall be cut and removed from the dikes and discharge channel. This shall be done as frequently as is necessary to insure that no tree reaches a size where the root structure would require removal and filling. Woody vegetation, shrubs, and trees shall be removed during the early stages of growth before reaching a three-inch diameter.

Low growing vegetation, a prairie grass mixture that grows to a height of no more than six inches, shall be planted and maintained to facilitate inspections.

3.2 Discharge Structure

Not applicable.

3.3 Animal Damage and Repairs

Animal burrows discovered during inspections shall be promptly repaired by filling with grout.

3.4 Restriction of Unauthorized Vehicles

Facility approaches shall be posted with signs restricting unauthorized travel on the roadways and slopes.

3.5 Inspections/Remedial Measures

3.5.1 Weekly Inspections

Weekly inspections of the perimeter berms shall be conducted, looking for seepage and slumping. All findings shall be entered into the weekly inspection checklist, discussed in Section 4.0. Maintenance activities shall be initiated, if required. Refer to Section 4.0 for the recommended inspection checklist to be used for the weekly inspections.

3.5.2 Quarterly Inspections

Inspections shall be made quarterly by Station personnel to determine the general condition of the dam and embankments. During these inspections, embankment erosion, tree growth, and embankment seepage shall be monitored. Seepage shall be observed for change in quantity and coloration. Refer to Section 4.0, for the recommended inspection checklist to be used for documenting the quarterly inspections.

3.5.3 Annual Inspections

An annual inspection shall be made by a licensed professional engineer. This inspection shall follow the Illinois Department of natural Resources (IDNR) *Guidelines and Forms for Inspection of Illinois Dams*, and shall be followed by verbal and written reports by the consulting engineer. Based on the findings of the inspection, the Station Manager shall implement corrective action as required to promote dam safety. Procedures and methods for corrective action shall be performed in accordance with recommendations of the consulting engineer and as outlined above. Because the dam is not permitted by the IDNR, copies of the engineer's report, along with corrective action taken, will not be reported to the IDNR.

4.0 INSPECTION CHECKLISTS

The following Inspection checklists should be used during the weekly and quarterly inspections.

WEEKLY DAM INSPECTION FORM

Dam Location: Hennepin Power Station – Old East Ash Pond
Owner: Dynegy Midwest Generation, LLC, Havana Power Station
Permit No.:Not permitted **Class of Dam: Not classified**
Type of Dam: Homogeneous earth dam
Type of Spillway: N/A

Date Inspected: _____
Weather Conditions: _____
Pool Elevation: _____

Inspection Personnel:

_____ _____
Name / Title **Signature**

Inspection Item	Conditions	Location of Problem and Recommended Remedial Measures and Implementation Schedule
Vertical and Horizontal Alignment of Crest		
Unusual Movement or Cracking at or Beyond Toe		
Seepage		
Vegetative Cover		
Embankment Erosion		
Structural Cracking		
Outfall Structures		
Other		

QUARTERLY DAM INSPECTION FORM

Dam Location: Hennepin Power Station – Old East Ash Pond
Owner: Dynegy Midwest Generation, LLC, Hennepin Power Station
Permit No.: Not permitted **Class of Dam: Not classified**
Type of Dam: Homogeneous earth dam
Type of Spillway: Not applicable

Date Inspected: _____
Weather Conditions: _____
Pool Elevation: _____

Inspection Personnel:

_____
Name / Title **Signature**

Inspection Item	Conditions	Location of Problem and Recommended Remedial Measures and Implementation Schedule
Vertical and Horizontal Alignment of Crest	Good condition, with no significant issues	
Downstream Fill Slopes	Good condition, with no significant issues	
Upstream Fill Slopes	Good condition, with no significant issues	
Unusual Movement or Cracking at or Beyond Toe	Good condition, with no significant issues	
Seepage (Condition/Color)	Good condition, with no significant issues	
Vegetative Cover (Tree growth)	Good condition, with no significant issues	
Animal Damage	Good condition, with no significant issues	
Embankment Erosion	Good condition, with no significant issues	
Water Passages	Good condition, with no significant issues	
Structural Cracking	Good condition, with no significant issues	
Outfall Structures	Good condition

Appendix G: Hennepin Power Station; East Ash Disposal Pond Maintenance Plan (2014)

DYNEGY MIDWEST GENERATION, LLC

Hennepin Power Station
Hennepin, Illinois

Putnam County

East Ash Disposal Pond

Small Class III Dam

IDNR Permit No. DS2011079

Dam ID No. IL50363

Maintenance Plan

Revised – August 2014

TABLE OF CONTENTS

Paragraph	Description	Page
1.0	GENERAL	1
2.0	EMERGENCY OPERATIONS	1
2.1	Unusual Conditions	1
2.2	Dewatering	2
3.0	MAINTENANCE	2
3.1	Vegetation	2
3.2	Discharge Structure	2
3.3	Animal Damage and Repairs	2
3.4	Restriction of Unauthorized Vehicles	2
3.5	Inspections/Remedial Measures	3
3.5.1	Weekly Inspections	3
3.5.2	Quarterly Inspections	3
3.5.3	Five-year Inspections	
3.6	Annual Statement	3
4.0	INSPECTION CHECKLISTS	3

1.0 GENERAL

The following operations and maintenance procedures are provided to maintain the structural integrity of the east ash storage surface impoundment at the Hennepin Power Station, which is classified as a small Class III dam by the Illinois Department of Natural Resources, Office of Water Resources. The primary pond's maximum normal poll elevation will be 489.5 msl with a dam crest at elevation 494.0 msl. The secondary pond's maximum normal pool elevation will be 480.5 with a dam crest at 494.0 msl.

2.0 EMERGENCY OPERATIONS

2.1 Unusual Conditions

Any unusual condition discovered during major storm events or routine inspection, which may constitute an emergency, shall be handled as follows. Notice of any type of emergency involving the dikes or outfall shall be made to the Shift Leader on duty [(815) 339-9211]. The Shift Leader on duty shall notify the Managing Director, Byron Veech [cell: (309) 543-8714], or, in his absence, the Environmental Coordinator, John P. Augspols [home: (815) 925-7488]. One of the above designated personnel shall notify the following city, county, state and federal regulatory authorities of the emergency condition.

- Division of Water Resources, Dam Safety Section, Dam Safety Engineers (217) 782-3862
- Illinois Emergency Management Agency, 24-hour service 1-(800) 782-7860
- Putnam County Sheriff/Hennepin Police Department (815) 925-7015
- Senior Director – Environmental Compliance, Dynegy Operating Company (618) 343-7761

2.2 Dewatering

The Station Manager or the Environmental Coordinator shall have the responsibility of determining how repairs shall be accomplished and whether dewatering of the disposal facility is necessary. Dewatering shall be accomplished by manually removing the concrete beams from the primary and/or secondary pond structures until the desired water level is reached.

3.0 MAINTENANCE

3.1 Vegetation

Dikes shall be maintained to protect the structural integrity of the disposal facility. Damaged and barren areas shall be repaired as soon as appropriate after being discovered. Damaged areas shall be filled with topsoil. Limed, fertilized, and seeded with appropriate vegetation. Trees and shrubs observed during periodic inspections shall be cut and removed from the dikes and discharge channel. This shall be done as frequently as is necessary to insure that no tree reaches a size where the root structure would require removal and filling. Woody vegetation, shrubs, and trees shall be removed during the early stages of growth before reaching a three-inch diameter.

Low growing vegetation shall be planted and maintained to facilitate inspections.

3.2 Discharge Structure

The discharge structure shall be inspected periodically for significant corrosion, spalling, and cracking. Any defects discovered shall be promptly repaired.

3.3 Animal Damage and Repairs

Animal burrows discovered during inspections shall be promptly repaired by filling with grout.

3.4 Restriction of Unauthorized Vehicles

Facility approaches shall be posted with signs restricting unauthorized travel on the roadways and slopes.

3.5 Inspections/Remedial Measures

3.5.1 Weekly Inspections

Weekly inspections of the perimeter berms shall be conducted, looking for seepage and slumping, and unusual seepage at and/or blockage of the outfall structures in each cell. All findings shall be entered into the weekly inspection checklist, discussed in Section 4.0. Maintenance activities shall be initiated, if required. Refer to Section 4.0 for the recommended inspection checklist to be used for the weekly inspections.

3.5.2 Quarterly Inspections

Inspections shall be made quarterly by Station personnel to determine the general condition of the dam and embankments. During these inspections, embankment erosion, tree growth, and embankment seepage shall be monitored. Seepage shall be observed for change in quantity and coloration. Refer to Section 4.0, for the recommended inspection checklist to be used for documenting the quarterly inspections.

3.5.3 Five-Year Inspections

Every five years, an inspection shall be made by a licensed professional engineer. This inspection shall follow the Illinois Department of natural Resources (IDNR) *Guidelines and Forms for Inspection of Illinois Dams*, and shall be followed by verbal and written reports by the consulting engineer. Based on the findings of the inspection, the Station Manager shall implement corrective action as required to promote dam safety. Procedures and methods for corrective action shall be performed in accordance with recommendations of the consulting engineer and as outlined above. Copies of the engineer's report, along with corrective actin taken, shall be reported to the IDNR.

3.6 Annual Statement

An annual statement on forms furnished by IDNR, certifying compliance with this maintenance plan, shall be submitted to IDNR.

4.0 INSPECTION CHECKLISTS

The following Inspection checklists should be used during the weekly and quarterly inspections.

WEEKLY DAM INSPECTION FORM

Dam Location: Hennepin Power Station – East Ash Pond
Owner: Dynegy Midwest Generation, LLC, Havana Power Station
Permit No.:DS2011079 **Class of Dam: III**
Type of Dam: Homogeneous earth dam, with clay and geosynthetic / clay liner
Type of Spillway: Drop structure and stop logs

APPENDIX D
TYPES OF CCR AND CHEMICAL CONSTITUENTS (845.220(a)(2)(A))

Hennepin Power Plant - West Ash Pond System's Chemical Constituents

In accordance with 35 I.A.C. 845.220(a)(2)(A), DMG is submitting an available/existing description of "the types of CCR expected in the CCR surface impoundment, including a chemical analysis of each type of expected CCR" in the closed CCR impoundment, West Ash Pond System.

A list of the chemical constituents' analyses contained in the DMG surface impoundment can be found in Appendix A. Appendix A contains chemical constituents found in the surface free liquid and the subsurface free liquids as determined through antidegradation studies. DMG is also including Safety Data Sheets for materials contains in the West Ash Pond System in Appendix B.

Appendix A: Chemical Constituents Contained in the West Ash Pond System

Parameter	Units	Surface Free Liquids Average Concentration	Subsurface Free Liquids Average Concentration
Ammonia (as N)	mg/L	<0.20	4
Arsenic, Dissolved (1)	mg/L	0.0061	0.059
Arsenic, Total	mg/L	0.0062	0.062
Barium, Total	mg/L	0.12	0.066
Boron, Total	mg/L	5.6	22
Cadmium, Dissolved	mg/L	<0.00050	0.0005
Cadmium, Total	mg/L	<0.00050	0.0008
Calcium, Total	mg/L	56	225
Chloride, Total	mg/L	22.5	4.35
Chromium, Dissolved	mg/L	<0.0050	0.016
Chromium, Hexavalent	mg/L	<0.010	0.02
Chromium, Hexavalent, Dissolved	mg/L	<0.010	0.020
Chromium, Total	mg/L	0.0029	0.018
Chromium, Trivalent, Dissolved	mg/L	<0.010	<0.01
Copper, Dissolved	mg/L	0.0016	0.0052
Copper, Total	mg/L	0.0023	0.0056
Cyanide, Amenable	mg/L	<0.0036	0.0043
Fluoride, Dissolved	mg/L	0.23	0.14
Fluoride, Total	mg/L	0.17	<0.20
Hardness (as calcium carbonate)	mg/L	170	570
Iron, Dissolved	mg/L	0.089	0.22
Iron, Total	mg/L	0.25	0.65
Lead, Dissolved	mg/L	0.00072	0.0024

DYNEGY

Safety Data Sheet

Section 1
Identification of the Substance and of the Supplier

1.1 Product Identifier

Product Name/Identification:	ASTM Class C Fly Ash
Synonyms:	Coal Fly Ash, Pozzolan
Formula:	UVCB Substance

1.2 Relevant Identified Uses of the Substance or Mixture and Uses Advices Against

Relevant Identified Uses:	Component of wallboard, concrete, roofing material, bricks, cement kiln feed.
Uses Advised Against:	None known.

1.3 Details of the Supplier of the SDS

Manufacturer/Supplier:	Dynegy, Inc.
Street Address:	601 Travis Street, Suite 1400
City, State and Zip Code:	Houston, TX 77002
Customer Service Telephone:	800-633-4704

Section 2
Hazards Identification

2.1 Classification of the Substance

GHS Classification(s) according to OSHA Hazard Communication Standard (29 CFR 1910.1200):

- Eye Irritant, Category 2A
- STOT-SE, Category 3 (Respiratory Irritation)
- Carcinogen, Category 1A
- STOT-RE, Category 1 (Lungs)
- Toxic to Reproduction, Category 2

2.2 Label Elements

Labelling according to 29 CFR 1910.1200 Appendices A, B and C*	
Hazard Pictogram(s):	
Signal word:	**DANGER**
Hazard Statement(s):	*Causes serious eye irritation.* *May cause damage to lungs after repeated/prolonged exposure via inhalation.* *May cause respiratory irritation.* *May cause cancer of the lung.* *Suspected of damaging fertility or the unborn child.*
Precautionary Statement(s):	*Obtain special instructions before use.* *Do not handle until all safety precautions have been read and understood.* *Avoid breathing dust.* *Wear protective gloves/protective clothing/eye protection/face protection.* *Wash thoroughly after handling.* *Do not eat drink or smoke when using this product.* *Use outdoors or in a well-ventilated area.* *If exposed or concerned: Get medical advice/attention.* *Store in a secure area.* *Dispose of product in accordance with local/national regulations.*

** Fly ash and other coal combustion products (CCPs) are UVCB substances (unknown or variable composition or biological). Various CCPs, noted as ashes/ash residuals; Ashes, residues, bottom; Bottom ash; Bottom ash residues; Waste solids, ashes under TSCA are defined as: "The residuum from the burning of a combination of carbonaceous materials. The following elements may be present as oxides: aluminum, calcium, iron, magnesium, nickel, phosphorus, potassium, silicon, sulfur, titanium, and vanadium." Ashes including fly ash and fluidized bed combustion ash are identified by CAS number 68131-74-8. The exact composition of the ash is dependent on the fuel source and flue additives composed of many constituents. The*

classification of the final substance is dependent on the presence of specific identified oxides as well as other trace elements.

2.3 Other Hazards

Listed Carcinogens:

-Respirable Crystalline Silica

IARC: [Yes] **NTP:** [Yes] **OSHA:** [Yes] **Other:** **(ACGIH)** [Yes]

Section 3
Composition/Information on Ingredients

Substance	***CAS No.***	***Percentage (%)***	***GHS Classification***
Crystalline Silica	*14808-60-7*	*30 - 60%*	*Repeat Dose STOT, Category 1* *Carcinogen, Category 1A*
Silica, crystalline respirable (RCS)	*14808-60-7*	***See Footnote 1***	*Repeat Dose STOT, Category 1* *Carcinogen, Category 1A*
Aluminosilicates	*71243-67-9* *1327-36-2*	*30 - 60%*	*Single Exposure STOT, Category 3*
Iron oxide	*1309-37-1*	*1 - 10%*	*Not Classified*
Calcium oxide (CaO)	*1305-78-8*	*20 - 30%*	*Skin Irritant, Category 2* *Eye Irritant, Category 1* *Single Exposure STOT, Category 3*
Magnesium oxide	*1309-48-4*	*2 - 10%*	*Not Classified*
Phosphorus pentoxide (P_2O_5)	*1314-56-3*	*≤2%*	*Skin Irritant, Category 2* *Eye Irritant, Category 2B*
Sodium oxide	*1313-59-3*	*1-8%*	*Not Classified*
Potassium oxide (K_2O)	*12136-45-7*	*≤1%*	*Skin Irritant, Category 2* *Eye Irritant, Category 2B*
Titanium dioxide (TiO_2)	*13463-67-7*	*<3%*	*Not Classified*
Bromide salt (calcium)	*7789-41-5*	*See Footnote 2*	*Toxic to Reproduction, Category 2*

Footnote 1: *The percentage of respirable crystalline silica has not been determined. Therefore, a GHS classification of Carcinogen, Category 1A has been assigned.*

Footnote 2: *Analytical data are not available to demonstrate that the concentration of bromide salt is <0.1%; therefore, a GHS classification of Toxic to Reproduction, Category 2 has been assigned.*

Section 4
First Aid Measures

4.1 Description of First Aid Measures

Inhalation:	If product is inhaled and irritation of the nose or coughing occurs, remove person to fresh air. Get medical advice/attention if respiratory symptoms persist.
Skin Contact:	If skin exposure occurs, wash with soap and water.
Eye Contact:	If product gets into the eye, rinse copiously with water for several minutes. Remove contact lenses, if present and easy to do. Seek medical attention/advice if irritation occurs or persists.
Ingestion:	No specific first aid measures are required.

4.2 Most Important Health Effects, Both Acute and Delayed

Acute Effects: Direct exposure may cause respiratory irritation, eye irritation and skin irritation. The product dust can dry and irritate the skin and cause dermatitis and can irritate eyes and skin through mechanical abrasion.

Chronic Effects: Chronic exposure may cause lung damage from repeated exposure. Prolonged inhalation of respirable crystalline silica above certain concentrations may cause lung diseases, including silicosis and lung cancer. Repeated exposure to dusts containing inorganic bromide salts may affect fertility and/or result in effects to the unborn child.

4.3 Indication of Any Immediate Medical Attention and Special Treatment Needed

Seek first aid or call a doctor or Poison Control Center if contact with eyes occurs and irritation remains after rinsing. Get medical advice if inhalation occurs and respiratory symptoms persist.

Section 5
Firefighting Measures

5.1 Extinguishing Media

Suitable Extinguishing Media:	Product is not flammable. Use extinguishing media appropriate for surrounding fire.
Unsuitable Extinguishing Media:	Not applicable, the product is not flammable.

5.2 Special Hazards Arising from the Substance or Mixture

Hazardous Combustion Products:	None known.

5.3 Advice for Firefighters

Special Protective Equipment and Precautions for Firefighters:	As with any fire, wear self-contained breathing apparatus (NIOSH approved or equivalent) and full protective gear.

Section 6
Accidental Release Measures

6.1 Personal Precautions, Protective Equipment and Emergency Procedures

Personal precautions/Protective Equipment:	See Section 8.2.2 Individual Protective Measures. For concentrations exceeding Occupational Exposure Levels (OELs), use a self-contained breathing apparatus (SCBA).
Emergency procedures:	Use scooping, water spraying/flushing/misting or ventilated vacuum cleaning systems to clean up spills. Do not use pressurized air.

6.2 Environmental Precautions

Environmental precautions:	Prevent contamination of drains or waterways and dispose according to local and national regulations.

6.3 Methods and Material for Containment and Cleaning Up

Methods and materials for containment and cleaning up:	Do not use brooms or compressed air to clean surfaces. Use dust collection vacuum and extraction systems. Large spills of dry product should be removed by a vacuum system. Dampened material should be removed by mechanical means and recycled or disposed of according to local and national regulations.

See Sections 8 and 13 for additional information on exposure controls and disposal.

Section 7
Handling and Storage

7.1 Precautions for Safe Handling

Practice good housekeeping. Use adequate exhaust ventilation, dust collection and/or water mist to maintain airborne dust concentrations below permissible exposure limits (note: respirable crystalline silica dust may be in the air without a visible dust cloud).

Do not permit dust to collect on walls, floors, sills, ledges, machinery, or equipment. Maintain and test ventilation and dust collection equipment. In cases of insufficient ventilation, wear a NIOSH approved respirator for silica dust when handling or disposing dust from this product. Avoid contact with skin and eyes. Wash or vacuum clothing that has become dusty. Avoid eating, smoking, or drinking while handling the material.

7.2 Conditions for Safe Storage, Including any Incompatibilities

Minimize dust produced during loading and unloading.

Section 8
Exposure Controls/Personal Protection

8.1 Control Parameters

OCCUPATIONAL EXPOSURE LIMITS					
SUBSTANCE		**OSHA PEL TWA (mg/m^3)**	**NIOSH REL TWA (mg/m^3)**	**ACGIH TLV TWA (mg/m^3)**	**CA - OSHA PEL (mg/m^3)**
Calcium oxide		5	2	2	2
Particulates Not Otherwise Regulated	Total	15	15	10	10
	Respirable	5	5	3	5
Respirable Crystalline Silica	Respirable Crystalline Silica	0.05	0.05	0.025	0.05
Titanium dioxide	Total	15	2.4 (fine) 0.3 (ultrafine)	10	10
Manganese dioxide (as manganese compounds)	Total	5 (Ceiling)	1 3 (STEL)	0.1	0.2
	Respirable	-	-	0.02	-

8.2 Exposure Controls

8.2.1 Engineering Controls

Provide ventilation to maintain the ambient workplace atmosphere below the occupational exposure limit(s). Use general and local exhaust ventilation and dust collection systems as necessary to minimize exposure.

8.2.2 Personal Protective Equipment (PPE)

Respiratory protection:	Wear a NIOSH approved particulate respirator if exposure to airborne particulates is unavoidable and where occupational exposure limits may be exceeded. If airborne exposures are anticipated to exceed applicable PELs or TLVs, a self-contained breathing apparatus or airline respirator is recommended.
Eye and face protection:	If eye contact is possible, wear protective glasses with side shields. Avoid contact lenses.
Hand and skin protection:	Wear gloves and protective clothing. Wash hands with soap and water after contact with material.

Section 9
Physical and Chemical Properties

9.1 Information on Basic Physical and Chemical Properties

Property: Value	Property: Value
Appearance (physical state, color, etc.): Fine tan/ gray particulate	**Upper/lower flammability or explosive limits:** Not applicable
Odor: Odorless[1]	**Vapor Pressure (Pa):** Not applicable
Odor threshold: Not applicable	**Vapor Density:** Not applicable
pH (25 °C) (in water): Not Determined	**Specific gravity or relative density:** 2.2 – 2.9
Melting point/freezing point (°C): Not applicable	**Water Solubility:** Slight
Initial boiling point/boiling range (°C): NA	**Partition coefficient: n-octane/water:** NA
Flash point (°C): Not determined	**Auto ignition temperature (°C):** Not applicable
Evaporation rate: Not applicable	**Decomposition temperature (°C):** Not determined
Flammability (solid, gas): Not combustible	**Viscosity:** Not applicable

[1] The use of urea or aqueous ammonia injected into the flue gas to reduce nitrogen oxides (NOx) emissions may result in the presence of ammonium sulfate or ammonium bisulfate in the ash at less than 0.1%. When ash containing these substances becomes wet under high pH (>9), free ammonia gas may be released resulting in objectionable/nuisance ammonia odor and potential exposure to ammonia gas especially in confined spaces.

Section 10
Stability and Reactivity

10.1 Reactivity:	The material is an inert, inorganic material primarily composed of elemental oxides.
10.2 Chemical stability:	The material is stable under normal use conditions.
10.3 Possibility of hazardous reactions:	The material is a relatively stable, inert material; however, when ash containing ammonia becomes wet under high pH (>9), free ammonia gas may be released resulting in an objectionable/nuisance ammonia odor and potential exposure to ammonia gas especially in confined spaces. Polymerization will not occur.
10.4 Conditions to avoid:	Product can become airborne in moderate winds. Dry material should be stored in silos. Materials stored out of doors should be covered or maintained in a damp condition.
10.5 Incompatible materials:	None known.
10. 6 Hazardous decomposition products:	None known.

Section 11
Toxicological Information

11.1 Information on Toxicological Effects

Endpoint	Data
Acute oral toxicity	LD50 > 2000 mg/kg
Acute dermal toxicity	LD50 > 2000 mg/kg
Acute inhalation toxicity	LD50 > 5.0 mg/L
Skin corrosion/irritation	Does not meet the classification criteria but may cause slight skin irritation. Product dust can dry the skin which can result in irritation.
Eye damage/irritation	Causes serious eye irritation. Positive scores for conjunctiva irritation and chemosis in 2/3 animals based on average of 24, 48 and 72-hour scores with irritation clearing within 21 days; No corneal or iritis effects observed.
Respiratory/skin sensitization	Not a respiratory or dermal sensitizer.
Germ cell mutagenicity	Not mutagenic in in-vitro and in-vivo assays with or without metabolic activation.
Carcinogenicity	Not available. Respirable crystalline silica has been identified as a carcinogen by OSHA, NTP, ACGIH and IARC.
Reproductive toxicity	No developmental toxicity was observed in available animal studies. Reproductive studies on CCPs showed either no reproductive effects, or some effects on male and female reproductive organs and parameters but without a clear dose response. Inorganic bromide salts have been shown to have adverse effects on reproductive parameters in some animal studies.
STOT-SE	CCPs when present as a nuisance dust may result in respiratory irritation.
STOT-RE	In a 180-day inhalation study with fly ash dust, no effects were observed at the highest dose tested. NOEC = 4.2 mg/m^3; it is not possible to assess the level at which toxicologically significant effects may occur. Repeated inhalation exposures to high levels of respirable crystalline silica may result in lung damage (i.e., silicosis).
Aspiration Hazard	Not applicable based product form.

Section 12
Ecological Information

12.1 Toxicity

Fly Ash C (CAS# 68131-74-8)	
Toxicity to Fish	LC50 > 100 mg/L
Toxicity to Aquatic Invertebrates	Data indicates that the test substance is not toxic to *Daphnia magna* (EC50 undetermined).
Toxicity to Aquatic Algae and Plants	EC50 = 10 mg/L

Calcium oxide CAS# 1305-78-8	
Toxicity to Fish	LC50 = 50.6 mg/L The findings were closely related to the pH of the test solutions; therefore, pH is considered to be the main reason for the effects.
Toxicity to Aquatic Invertebrates	EC50 = 49.1 mg/L The findings were closely related to the pH of the test solutions; therefore, pH is considered to be the main reason for the effects.
Toxicity to Aquatic Algae and Plants	NOEC =48 mg/L @ 72 hours based on $Ca(OH)_2$ The initial pH of the test medium was not directly related to the biologically relevant effects. The formation of precipitates is likely the result of the reaction between CO_2 dissolved in the medium.

12.2 Persistence and Degradability

Not relevant for inorganic materials.

12.3 Bioaccumulative Potential

This material does not contain any compounds that would bioaccumulate up the food chain.

12.4 Mobility in Soil

No data available.

12.5 Results of PBT and vPvB Assessment

This material does not contain any compounds classified as “persistent, bioaccumulative or toxic” nor as “very persistent/very bioaccumulative”.

12.6 Other Adverse Effects

None known.

Section 13

Disposal Considerations

See Sections 7 and 8 above for safe handling and use, including appropriate industrial hygiene practices.

Dispose of all waste product and containers in accordance with federal, state and local regulations.

Section 14
Transport Information

Regulatory entity: U.S. DOT	Shipping Name:	Not Regulated
	Hazard Class:	Not Regulated
	ID Number:	Not Regulated
	Packing Group:	Not Regulated

Section 15
Regulatory Information

15.1 Safety, Health and Environmental Regulations/Legislation Specific for the Mixture

- TSCA Inventory Status

  All components are listed on the TSCA Inventory.

- California Proposition 65.

  The following substances are known to the State of California to be carcinogens and/or reproductive toxicants:

  - Respirable crystalline silica

- State Right-to-Know (RTK)

Component	CAS	MA[1,2]	NJ[3,4]	PA[5]	RI[6]
Ammonium bisulfate	7803-63-6	No	Yes	No	No
Ammonium sulfate	7783-20-2	Yes	No	Yes	No
Calcium oxide	1305-78-8	Yes	Yes	Yes	No
Iron oxide	1309-37-1	Yes	Yes	Yes	No
Magnesium oxide	1309-48-4	No	Yes	No	No
Manganese oxide-as manganese compounds	1313-13-9; Various	No	No	Yes	Yes
Phosphorus pentoxide (or phosphorus oxide)	1314-56-3	Yes	Yes	Yes	No
Potassium oxide	12136-45-7	No	Yes	No	No
Silica-crystalline (SiO2), quartz	14808-60-7	Yes	Yes	Yes	No
Sodium oxide	1313-59-3	No	Yes	No	No
Titanium dioxide	13463-67-7	Yes	Yes	Yes	Yes

- SCBA: Self-contained breathing apparatus
- SDS: Safety Data Sheet
- STEL: Short-term exposure limit
- STOT-RE: Specific target organ toxicity-repeated exposure
- STOT-SE: Specific target organ toxicity-single exposure
- TLV: Threshold limit value
- TSCA: Toxic Substances Control Act
- TWA: Time-weighted average
- UEL: Upper explosive limit
- UVCB: Unknown or Variable Composition/Biological
- U.S.: United States
- U.S. DOT: United States of Department of Transportation

16.3 Other Hazards

Hazardous Materials Identification System (HMIS) Degree of hazard (0= low, 4 = extreme)							
Health:	2*	**Flammability:**	0	**Physical Hazards:**	0	**Personal protection:****	

** Chronic Health Effects*
*** Appropriate personal protection is defined by the activity to be performed.*
See Section 8 for additional information.

DISCLAIMER:

This SDS has been prepared in accordance with the Hazard Communication Rule 29 CFR 1910.1200. Information herein is based on data considered to be accurate as of date prepared. No warranty or representation, express or implied, is made as to the accuracy or completeness of this data and safety information. No responsibility can be assumed for any damage or injury resulting from abnormal use, failure to adhere to recommended practices, or from any hazards inherent in the nature of the product.

DYNEGY

Safety Data Sheet

Section 1
Identification of the Substance and of the Supplier

1.1 Product Identifier

Product Name/Identification:	ASTM Bottom Ash
Synonyms:	Ash; Ashes; Ash residues; Ashes, residues, bottom; Bottom ash; Bottom ash residues; Coal Fly Ash; Pozzolan; Waste solids.
Formula:	UVCB Substance

1.2 Relevant Identified Uses of the Substance or Mixture and Uses Advices Against

Relevant Identified Uses:	Component of wallboard, concrete, roofing material, bricks, cement kiln feed.
Uses Advised Against:	None known.

1.3 Details of the Supplier of the SDS

Manufacturer/Supplier:	Dynegy, Inc.
Street Address:	601 Travis Street, Suite 1400
City, State and Zip Code:	Houston, TX 77002
Customer Service Telephone:	800-633-4704

Section 2
Hazards Identification

2.1 Classification of the Substance

GHS Classification(s) according to OSHA Hazard Communication Standard (29 CFR 1910.1200):

- Eye Irritant, Category 2A
- STOT-SE, Category 3 (Respiratory Irritation)
- Carcinogen, Category 1A
- STOT-RE, Category 1 (Lungs)
- Toxic to Reproduction, Category 2

2.2 Label Elements

Labelling according to 29 CFR 1910.1200 Appendices A, B and C*	
Hazard Pictogram(s):	
Signal word:	**DANGER**
Hazard Statement(s):	*Causes serious eye irritation.* *May cause respiratory irritation.* *May cause damage to lungs after repeated/prolonged exposure via inhalation.* *May cause cancer of the lung.* *Suspected of damaging fertility or the unborn child.*
Precautionary Statement(s):	*Obtain special instructions before use.* *Do not handle until all safety precautions have been read and understood.* *Avoid breathing dust.* *Wash thoroughly after handling.* *Do not eat drink or smoke when using this product.* *Wear protective gloves/protective clothing/eye protection/face protection.* *Use outdoors or in a well-ventilated area.* *If exposed or concerned: Get medical advice/attention.* *Store in a secure area.* *Dispose of product in accordance with local/national regulations.*

** Fly ash and other coal combustion products (CCPs) are UVCB substances (unknown or variable composition or biological). Various CCPs, noted as ashes/ash residuals; Ashes, residues, bottom; Bottom ash; Bottom ash residues; Waste solids, ashes under TSCA are defined as: "The residuum from the burning of a combination of carbonaceous materials. The following elements may be present as oxides: aluminum, calcium, iron, magnesium, nickel, phosphorus, potassium, silicon, sulfur, titanium, and vanadium." Ashes including fly ash and fluidized bed combustion ash are identified by CAS number 68131-74-8. The exact composition of the ash is dependent on the fuel source and flue additives composed of many constituents. The classification of the final substance is dependent on the presence of specific identified oxides as well as other trace elements.*

2.3 Other Hazards

Listed Carcinogens:

-Respirable Crystalline Silica

IARC: [Yes] **NTP:** [Yes] **OSHA:** [Yes] **Other:** **(ACGIH)** [Yes]

Section 3
Composition/Information on Ingredients

Substance	CAS No.	Percentage (%)	GHS Classification
Crystalline Silica	14808-60-7	20 - 40%	Repeat Dose STOT, Category 1 Carcinogen, Category 1A
Silica, crystalline respirable (RCS)	14808-60-7	See Footnote 1	Repeat Dose STOT, Category 1 Carcinogen. Category 1A
Aluminosilicates[2]	Various, see Footnote 2	10 - 60%	Single Exposure STOT, Category 3
Calcium oxide (CaO)	1305-78-8	10 - 30%	Skin Irritant, Category 2 Eye Irritant, Category 1 Single Exposure STOT, Category 3
Iron oxide	1309-37-1	1 - 10%	Not Classified
Manganese dioxide (MnO_2)	1313-13-9	<2%	Skin Irritant, Category 2 Eye Irritant, Category 2B
Magnesium oxide	1309-48-4	2 - 10%	Not Classified
Phosphorus pentoxide (P_2O_5)	1314-56-3	≤2%	Skin Irritant, Category 2 Eye Irritant, Category 2B
Sodium oxide	1313-59-3	1 - 10%	Not Classified
Potassium oxide (K_2O)	12136-45-7	≤1%	Skin Irritant Category 2 Eye Irritant Category 2B
Titanium dioxide (TiO_2)	13463-67-7	<3%	Not Classified

[1]The percentage of respirable crystalline silica has not been determined. Therefore, a GHS classification of Carcinogen 1A has been assigned.

[2]Aluminosilicates (CAS# 1327-36-2) may be in the form of mullite (CAS# 1302-93-8); aluminosilicate glass; pozzolans (CAS# 71243-67-9); or calcium aluminosilicates such as tricalcium aluminate (C3A), or calcium sulfoaluminate (C4A3S). The form is dependent on the source of the coal and or the process used to create the CCP. Pulverized coal combustion would be more likely to create high levels of pozzolans. Aluminosilicates may have inclusions of calcium, titanium, iron, potassium, phosphorus, magnesium and other metal oxides.

Section 4
First Aid Measures

4.1 Description of First Aid Measures

Inhalation:	If product is inhaled and irritation of the nose or coughing occurs, remove person to fresh air. Get medical advice/attention if respiratory symptoms persist.
Skin Contact:	If skin exposure occurs, wash with soap and water.
Eye Contact:	If product gets into the eye, rinse copiously with water for several minutes. Remove contact lenses, if present and easy to do. Seek medical attention/advice if irritation occurs or persists.
Ingestion:	No specific first aid measures are required.

4.2 Most Important Health Effects, Both Acute and Delayed

Acute Effects: Direct exposure may cause respiratory irritation, eye irritation and skin irritation. The product dust can dry and irritate the skin and cause dermatitis and can irritate eyes and skin through mechanical abrasion.

Chronic Effects: Chronic exposure may cause lung damage from repeated exposure. Prolonged inhalation of respirable crystalline silica above certain concentrations may cause lung diseases, including silicosis and lung cancer.

4.3 Indication of Any Immediate Medical Attention and Special Treatment Needed

Seek first aid or call a doctor or Poison Control Center if contact with eyes occurs and irritation remains after rinsing. Get medical advice if inhalation occurs and respiratory symptoms persist.

Section 5
Firefighting Measures

5.1 Extinguishing Media

Suitable Extinguishing Media:	Product is not flammable. Use extinguishing media appropriate for surrounding fire.
Unsuitable Extinguishing Media:	Not applicable, the product is not flammable.

5.2 Special Hazards Arising from the Substance or Mixture

Hazardous Combustion Products:	None known.

5.3 Advice for Firefighters

Special Protective Equipment and Precautions for Firefighters:	As with any fire, wear self-contained breathing apparatus (NIOSH approved or equivalent) and full protective gear.

Section 6
Accidental Release Measures

6.1 Personal Precautions, Protective Equipment and Emergency Procedures

Personal precautions/Protective Equipment:	See Section 8.2.2 Individual Protective Measures. For concentrations exceeding Occupational Exposure Levels (OELs), use a self-contained breathing apparatus (SCBA).
Emergency procedures:	Use scooping, water spraying/flushing/misting or ventilated vacuum cleaning systems to clean up spills. Do not use pressurized air.

6.2 Environmental Precautions

Environmental precautions:	Prevent contamination of drains or waterways and dispose according to local and national regulations.

6.3 Methods and Material for Containment and Cleaning Up

Methods and materials for containment and cleaning up:	Do not use brooms or compressed air to clean surfaces. Use dust collection vacuum and extraction systems. Large spills of dry product should be removed by a vacuum system. Dampened material should be removed by mechanical means and recycled or disposed of according to local and national regulations.

See Sections 8 and 13 for additional information on exposure controls and disposal.

Section 7
Handling and Storage

7.1 Precautions for Safe Handling

Practice good housekeeping. Use adequate exhaust ventilation, dust collection and/or water mist to maintain airborne dust concentrations below permissible exposure limits (note: respirable crystalline silica dust may be in the air without a visible dust cloud).

Do not permit dust to collect on walls, floors, sills, ledges, machinery, or equipment. Maintain and test ventilation and dust collection equipment. In cases of insufficient ventilation, wear a NIOSH approved respirator for silica dust when handling or disposing dust from this product. Avoid contact with skin and eyes. Wash or vacuum clothing that has become dusty. Avoid eating, smoking, or drinking while handling the material.

7.2 Conditions for Safe Storage, Including any Incompatibilities

Minimize dust produced during loading and unloading.

Section 8
Exposure Controls/Personal Protection

8.1 Control Parameters

OCCUPATIONAL EXPOSURE LIMITS					
SUBSTANCE		**OSHA PEL TWA (mg/m^3)**	**NIOSH REL TWA (mg/m^3)**	**ACGIH TLV TWA (mg/m^3)**	**CA - OSHA PEL (mg/m^3)**
Calcium oxide		5	2	2	2
Particulates Not Otherwise Regulated	Total	15	15	10	10
	Respirable	5	5	3	5
Respirable Crystalline Silica	Respirable	0.05	0.05	0.025	0.05
Manganese dioxide (as manganese compounds)	Total	5 (Ceiling)	1 3 (STEL)	0.1	0.2
	Respirable	-	-	0.02	-

8.2 Exposure Controls

8.2.1 Engineering Controls

Provide ventilation to maintain the ambient workplace atmosphere below the occupational exposure limit(s). Use general and local exhaust ventilation and dust collection systems as necessary to minimize exposure.

8.2.2 Personal Protective Equipment (PPE)

Respiratory protection:	Wear a NIOSH approved particulate respirator if exposure to airborne particulates is unavoidable and where occupational exposure limits may be exceeded. If airborne exposures are anticipated to exceed applicable PELs or TLVs, a self-contained breathing apparatus or airline respirator is recommended.
Eye and face protection:	If eye contact is possible, wear protective glasses with side shields. Avoid contact lenses.
Hand and skin protection:	Wear gloves and protective clothing. Wash hands with soap and water after contact with material.

Section 9
Physical and Chemical Properties

9.1 Information on Basic Physical and Chemical Properties

Property: Value	Property: Value
Appearance (physical state, color, etc.): Fine tan/ gray particulate	**Upper/lower flammability or explosive limits:** Not applicable
Odor: Odorless[1]	**Vapor Pressure (Pa):** Not applicable
Odor threshold: Not applicable	**Vapor Density:** Not applicable
pH (25 °C) (in water): 8 - 11	**Specific gravity or relative density:** 2.2 – 2.9
Melting point/freezing point (°C): Not applicable	**Water Solubility:** Slight
Initial boiling point and boiling range (°C): Not applicable	**Partition coefficient: n-octane/water:** Not determined
Flash point (°C): Not determined	**Auto ignition temperature (°C):** Not applicable
Evaporation rate: Not applicable	**Decomposition temperature (°C):** Not determined
Flammability (solid, gas): Not combustible	**Viscosity:** Not applicable

[1] The use of urea or aqueous ammonia injected into the flue gas to reduce nitrogen oxides (NOx) emissions may result in the presence of ammonium sulfate or ammonium bisulfate in the ash at less than 0.1%. When ash containing these substances becomes wet under high pH (>9), free ammonia gas may be released resulting in objectionable/nuisance ammonia odor and potential exposure to ammonia gas especially in confined spaces.

Section 10
Stability and Reactivity

10.1 Reactivity:	The material is an inert, inorganic material primarily composed of elemental oxides.
10.2 Chemical stability:	The material is stable under normal use conditions.
10.3 Possibility of hazardous reactions:	The material is a relatively stable, inert material; however, when ash containing ammonia becomes wet under high pH (>9), free ammonia gas may be released resulting in an objectionable/nuisance ammonia odor and potential exposure to ammonia gas especially in confined spaces. Polymerization will not occur.
10.4 Conditions to avoid:	Product can become airborne in moderate winds. Dry material should be stored in silos. Materials stored out of doors should be covered or maintained in a damp condition.
10.5 Incompatible materials:	None known.
10. 6 Hazardous decomposition products:	None known.

Section 11
Toxicological Information

11.1 Information on Toxicological Effects

Endpoint	Data
Acute oral toxicity	LD50 > 2000 mg/kg
Acute dermal toxicity	LD50 > 2000 mg/kg
Acute inhalation toxicity	LD50 > 5.0 mg/L
Skin corrosion/irritation	Does not meet the classification criteria but may cause slight skin irritation. Product dust can dry the skin which can result in irritation.
Eye damage/irritation	Causes serious eye irritation. Positive scores for conjunctiva irritation and chemosis in 2/3 animals based on average of 24, 48 and 72-hour scores with irritation clearing within 21 days; no corneal or iritis effects observed.
Respiratory/skin sensitization	Not a respiratory or dermal sensitizer.
Germ cell mutagenicity	Not mutagenic in in-vitro and in-vivo assays with or without metabolic activation.
Carcinogenicity	Not available. Respirable crystalline silica has been identified as a carcinogen by OSHA, NTP, ACGIH and IARC.
Reproductive toxicity	No developmental toxicity was observed in available animal studies. Reproductive studies on CCPs showed either no reproductive effects, or some effects on male and female reproductive organs and parameters but without a clear dose response.
STOT-SE	CCPs when present as a nuisance dust may result in respiratory irritation.
STOT-RE	In a 180-day inhalation study with fly ash dust, no effects were observed at the highest dose tested. NOEC = 4.2 mg/m^3; it is not possible to assess the level at which toxicologically significant effects may occur. Repeated inhalation exposures to high levels of respirable crystalline silica may result in lung damage (i.e., silicosis).
Aspiration Hazard	Not applicable based product form.

Section 12
Ecological Information

12.1 Toxicity

Fly Ash (CAS# 68131-74-8)	
Toxicity to Fish	LC50 > 100 mg/L
Toxicity to Aquatic Invertebrates	Data indicates that the test substance is not toxic to *Daphnia magna* (EC50 undetermined)
Toxicity to Aquatic Algae and Plants	EC50 = 10 mg/L
Calcium oxide CAS# 1305-78-8	
Toxicity to Fish	LC50 = 50.6 mg/L The findings were closely related to the pH of the test solutions; therefore, pH is considered to be the main reason for the effects.
Toxicity to Aquatic Invertebrates	EC50 = 49.1 mg/L The findings were closely related to the pH of the test solutions; therefore, pH is considered to be the main reason for the effects.
Toxicity to Aquatic Algae and Plants	NOEC =48 mg/L @ 72 hours based on $Ca(OH)_2$ The initial pH of the test medium was not directly related to the biologically relevant effects. The formation of precipitates is likely the result of the reaction between CO_2 dissolved in the medium.

12.2 Persistence and Degradability

Not relevant for inorganic materials.

12.3 Bioaccumulative Potential

This material does not contain any compounds that would bioaccumulate up the food chain.

12.4 Mobility in Soil

No data available.

12.5 Results of PBT and vPvB Assessment

This material does not contain any compounds classified as “persistent, bioaccumulative or toxic” nor as “very persistent/very bioaccumulative”.

12.6 Other Adverse Effects

None known.

Section 13
Disposal Considerations

See Sections 7 and 8 above for safe handling and use, including appropriate industrial hygiene practices.

Dispose of all waste product and containers in accordance with federal, state and local regulations.

Section 14
Transport Information

Regulatory entity: U.S. DOT	Shipping Name:	Not Regulated
	Hazard Class:	Not Regulated
	ID Number:	Not Regulated
	Packing Group:	Not Regulated

Section 15
Regulatory Information

15.1 Safety, Health and Environmental Regulations/Legislation Specific for the Mixture

- TSCA Inventory Status

  All components are listed on the TSCA Inventory.

- California Proposition 65

  The following substances are known to the State of California to be carcinogens and/or reproductive toxicants:

  - Respirable crystalline silica
  - Titanium dioxide

- State Right-to-Know (RTK)

Component	CAS	MA[1,2]	NJ[3,4]	PA[5]	RI[6]

1. INTRODUCTION

1.1 Plant and Site Information

Dynegy Midwest Generation, LLC (DMG) is the owner of the inactive coal-fired Hennepin Power Plant (HPP), also referred to as the Hennepin Power Station (HEN), in Hennepin, Putnam County, Illinois. DMG intends to complete groundwater corrective action of the coal combustion residuals (CCR) surface impoundment (SI) West Ash Pond System (WAPS), which is identified by Illinois Environmental Protection Agency (IEPA) identification (ID) numbers (No.) W1550100002-01 and W1550100002-03, CCR Unit ID No. 804, and a National Inventory of Dams (NID) No. IL50698. The WAPS is comprised of the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). The WAPS was constructed as a single unit with a single perimeter dike and subsequently internally divided into the OWAP and OWPP as part of operational practices. Source control (*e.g.*, closure) was completed in 2020; this included leaving CCR in place within the OWAP, removing all CCR from the OWPP, placing it within the OWAP, and installing a geomembrane final cover system over the consolidated OWAP [1, 2]. This document and all past engineering and hydrogeological studies consider the WAPS as a single CCR unit. This Corrective Action Plan (CAP) has been prepared for the WAPS at HPP under the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments [3] and the requirements of Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257, herein referred to as the Federal CCR Rule [4].

1.2 Organization of the Corrective Action Plan

This CAP is organized in the following manner:

- Section 1 includes an introduction to the WAPS, lists the status of other 35 I.A.C. § 845 permit applications submitted to IEPA, identifies the selected remedy, and provides a narrative of remedy construction;
- Section 2 includes an overview of the corrective action process, including the results of the Corrective Measures Assessment (CMA) and Corrective Action Alternatives Analysis (CAAA);
- Section 3 provides the CAP requirements, the selected remedy, an evaluation of effectiveness and an implementation schedule, as required by 35 I.A.C. § 845.670; and
- Section 4 includes reference documents used in the development of this CAP.

This CAP was prepared as an appendix to a Corrective Action Construction Permit (CP) application, to support obtaining a permit for Corrective Action Construction at the WAPS, as required by 35 I.A.C. § 845.220(a) and (c).

1.3 Permit Status

An Operating Permit (OP) application, as required by 35 I.A.C. § 845.230, was submitted on October 25, 2021 [5]. The permit application is currently under review by IEPA.

1.4 Closure and Source Control Status

DMG completed significant source control efforts in 2020 as part of final closure of the WAPS [1, 2]. The final closure was performed in accordance with the Closure and Post-Closure Care Plan [6] that was developed in accordance with 40 C.F.R. § 257, submitted to IEPA for review, and subsequently approved by IEPA [7]. IEPA found *"…the closure and post-closure care plan…to be*

an adequate corrective action" [8]. The final closure was addressed in accordance with the IEPA Water Pollution Control Permit 202-EA-65026-1.

The WAPS closure included a hybrid consolidate-and-cap approach comprised of closure-by-removal (CBR) of the OWPP and closure-in-place (CIP) of the OWAP. This involved excavating CCR and approximately 1 foot of soil below the CCR from the OWPP and placing it into the OWAP, and installing a geomembrane final cover system over the consolidated OWAP in accordance with 40 C.F.R. § 257.102 [1, 2]. These source control activities serve as the primary groundwater corrective measure for the WAPS.

Since final closure in 2020, groundwater quality has improved evidenced by a decrease in boron concentrations [9] within the groundwater monitoring network. Specifically, many wells where boron concentrations were above the groundwater protection standard (GWPS) of 2 milligrams per liter (mg/L) before closure (*e.g.*, wells 22, 21/21R, and 51) have, since closure, attained GWPS, or concentration levels have steadily decreased.

The remedy presented within this CAP is intended to be supplementary to the primary remedy, which is the completed source control.

1.5 Selected Corrective Action Remedy

A source control with continuous containment system (CCS), which combines source control that has been implemented at WAPS [1, 2] with a proposed deep cutoff wall (DCW) anchored (*i.e.,* extended) into competent bedrock, has been identified as the most appropriate remedy for the WAPS, based on the CAAA provided in **Appendix A**. The CCS will provide a continuous, passive, and essentially maintenance-free containment of the CCR within the WAPS, thereby controlling the source of releases of constituents listed in 35 I.A.C. § 845.60.

Potential remedies evaluated in the CAAA included Source Control with Groundwater Polishing (GWP) and Source Control with DCW. The CAAA, which was prepared by Gradient Corporation (Gradient), was based on a CAAA Supporting Information Report (CAAA-SIR) that was prepared by Ramboll Americas Engineering Solutions, Inc. (Ramboll) and is attached to the CAAA. The CAAA-SIR includes the results of groundwater modeling and feasibility-level design information for each remedy.

A Groundwater Polishing Evaluation Report [10] is also attached to the CAAA. This report presents results from geochemical modeling of exceedance[1] parameters addressed at WAPS by the CAP. Geochemical modeling is intended to contextualize the estimated time to reach the GWPS by evaluating the potential for chemical attenuation of exceedance parameters; and, for evaluating the potential for previously attenuated constituents of concern (COCs) to be remobilized under return-to-background conditions.

1.5.1 Narrative Description of Selected Corrective Action Remedy

Corrective action will consist of supplementing the completed source control [1, 2] through the installation of a vertically- and laterally-continuous, permanent, and low-permeability DCW that

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPS as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of DMG's OP Application for the HPP WAPS. That OP Application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, DMG has not identified any actual exceedances.

will extend from the perimeter dikes of the WAPS into low-permeability competent bedrock beneath the WAPS. This will result in the CCR within the WAPS being physically isolated from the environment on all sides by a permanent, passive system of continuous low-permeability barriers, including the final cover system on the surface, the DCW laterally, and competent shale bedrock below the base.

Once installed, the CCS will be a permanent corrective action feature. Performance of the CCS as groundwater corrective action will be monitored in accordance with the Corrective Action Groundwater Monitoring Plan (GMP) attached to the CP Application.

Estimated times to reach the GWPS will be periodically reviewed and updated based on observed corrective action performance via an adaptive site management strategy. These periodic, updated estimates will be communicated to IEPA and the public within annual corrective action monitoring reports, in accordance with the Corrective Action GMP.

Corrective action will be considered complete when a demonstration that GWPS compliance beyond the waste boundary has been achieved for at least three years and a Corrective Action Completion Report and Certification have been submitted to IEPA in accordance with 35 I.A.C. § 845.680(e).

1.5.1.1 Narrative Discussion of Remedy Design and Function

The CCS, which includes the DCW, final cover system, and competent bedrock base, includes the following features:

- The DCW portion of the remedy will be a continuous feature that will encircle the perimeter of the OWAP, with a total length of approximately 5,200 feet.
  - Since CCR from the OWPP was excavated and placed in the OWAP during WAPS closure [1, 2], this will encircle the remaining CCR contained within the WAPS.
- The DCW will be anchored (*i.e.,* extended) at least 1 foot into competent, low-permeability shale bedrock beneath the WAPS, which has a typical depth of approximately 90 feet below ground surface (bgs).
  - In 2024, packer testing was conducted at three boreholes (B-100, B-101, and B-102) adjacent to the WAPS. The results are summarized in a technical memorandum that will be included within an appendix to the CAAA (**Appendix A**) at a later date.
  - The competent shale bedrock was determined to have a hydraulic conductivity ranging from 1.1×10^{-5} centimeters per second (cm/sec) to 3.2×10^{-6} cm/sec, with a geometric mean hydraulic conductivity of 3.4×10^{-6} cm/sec.
  - The field measured hydraulic conductivity from wells at the WAPS is approximately 1.2×10^{-2} cm/sec for the gravel deposits of the Henry Formation [11], the geometric mean of the hydraulic conductivity of the shale bedrock is on the order 3,500 times (*i.e.,* nearly 4 orders of magnitude) lower than that of the overlying aquifer materials. Additionally, the observed hydraulic conductivity of the competent shale bedrock either remained consistent or decreased with depth. This demonstrates that the shale bedrock has an appropriately low hydraulic conductivity to function as a lower barrier layer for the CCS.
  - A summary of the 2024 packer testing results at boreholes B-100 through B-102 are presented in **Table 1**.

- The DCW will be constructed using a mixture of either soil and bentonite or cement and bentonite and would have a typical thickness of approximately 3 to 4 feet.
  - The target hydraulic conductivity for the DCW will be 1×10^{-7} cm/sec. This is approximately 120,000 times (*i.e.*, 5 orders of magnitude) lower than that of the surrounding aquifer materials (1.2×10^{-2} cm/sec for the gravel deposits of the Henry Formation [11]). This will result in the wall having an appropriately low hydraulic conductivity to function as a lateral barrier for the CCS.
- After installation of the DCW, the existing final cover system, which utilizes a low-permeability, 40-mil linear low-density polyethylene (LLDPE) geomembrane barrier layer, will be extended over the top of the final cover system.
- After CCS construction is complete, CCR within the WAPS will be continuously contained by low-permeability materials and isolated from the surrounding environment on all sides, including:
  - Surface containment will be provided by the existing and extended final cover system, which utilizes a low-permeability 40-mil LLDPE geomembrane, on the top of the CCR.
  - Lateral containment will be provided by the DCW on all sides of the CCR.
  - Lower containment will be provided by the low-permeability competent shale bedrock beneath the CCR.

Permit-level engineering drawings depicting the proposed DCW and other features, including areas of the WAPS where the final cover will be disturbed, repaired, and extended as part of DCW construction, are provided in **Appendix B**.

1.5.2 Narrative Description of Proposed Remedy Operations

No corrective action operations and maintenance (O&M) is expected to be required following installation of the DCW with integration into the competent bedrock portions of the CCS, as they are passive, below-grade structures. However, O&M of the final cover system portion of the CCS remedy would continue in accordance with current post-closure care O&M practices [6].

1.5.3 Narrative Description of Proposed Groundwater Monitoring

Corrective action groundwater monitoring will be conducted in accordance with the Corrective Action GMP during remedy operation to evaluate the effectiveness of the corrective action remedy and whether groundwater concentrations are achieving the GWPS as predicted by the groundwater model. Groundwater data collected as part of the monitoring program will be analyzed to determine if the remedy is on track to meet GWPS and to inform adaptive management decisions if performance metrics are not achieved. Information associated with each of these activities is described below.

- Regular groundwater monitoring will be conducted utilizing a corrective action groundwater monitoring network designed in accordance with 35 I.A.C. § 845.680(a)(1).
- Laboratory parameters include major ions for evaluating groundwater chemistry and COCs (*i.e.*, reported exceedances in accordance with the Operating GMP) the corrective action is intended to address. Sampling to evaluate corrective action effectiveness will begin the quarter after the corrective action remedy is implemented and commissioned. Samples will be collected on a quarterly basis initially and potentially reduced to a semiannual basis once

five years of monitoring have occurred, in accordance with 35 I.A.C. § 845.650(b)(4). Monitoring results will be submitted to IEPA for each monitoring event, in addition to an Annual Groundwater Monitoring and Corrective Action Report, in accordance with 35 I.A.C. § 845.610(e).

- Routine maintenance of the monitoring well network will include inspecting the wells, making repairs to the wells (as needed), and rehabilitating and/or replacing wells to improve performance (as needed).
- Adaptive site management strategies will be employed as an integral part of ongoing corrective action at the WAPS. The adaptive site management approach will allow timely incorporation of new site information to ensure the achievement of the GWPS. The effectiveness of the remedy at each phase is evaluated using performance metrics designed to assess the goals of that phase. Performance metrics answer questions designed to evaluate multiple aspects of remedy effectiveness with the ultimate goal of holistically guiding management decisions [12]. The goals and performance metrics of each phase of remedy evaluation are presented in Section 3 of the Corrective Action GMP included in the CP Application.
- Documentation of remedy progress metrics will be provided in the Annual Groundwater Monitoring and Corrective Action Report beginning after the second year of data collection: a minimum of eight data points is required to complete meaningful statistical analysis required for evaluation of the remedy progress metrics, which will be available after two years of quarterly sampling. Per United States Environmental Protection Agency (USEPA) guidance [12], a thorough review of corrective action progress and remedy effectiveness will be conducted every five years. A Five-Year Annual Groundwater Monitoring and Corrective Action Report will evaluate the comprehensive data set and, if triggered by the results of the remedy progress evaluation metrics, evaluate whether adaptive management actions are needed. The five-year time frame allows adaptive management decisions to be based on a robust data sufficient to complete meaningful statistical analysis while remaining responsive to changing site conditions [12].
- Corrective Action Confirmation Monitoring and Completion
  - Per 35 I.A.C. § 845.680(c), corrective action is considered complete when compliance with the GWPS has been demonstrated "at all points within the plume of contamination that lies beyond the waste boundary […] for a period of three consecutive years". At that time, an attainment evaluation will be implemented in accordance 35 I.A.C. § 845.680(c).
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification will be prepared and submitted to IEPA, in accordance with 35 I.A.C. § 845.680(e).

2. CORRECTIVE ACTION OVERVIEW

This CAP is based on the tiered assessment and analysis of alternative remedial technologies and remedies that were completed via the CMA and CAAA (**Appendix A**). The objective of these assessments was to determine the optimal alternative for the WAPS that, when coupled with the source control that has been previously implemented [1, 2], would remediate groundwater and provide compliance with the GWPS specified under 35 I.A.C. § 845.600.

2.1 Corrective Measures Assessment

The CMA [13] was performed for the WAPS and submitted to the IEPA on May 8, 2024, after the exceedances of the GWPS were identified. The CMA considered a total of five corrective measures for the WAPS, including:

- Source Control with GWP
- Source Control with *In-Situ* Stabilization/Solidification (ISS)
- Source Control with Groundwater Extraction (groundwater pumping wells or collection trenches)
- Source Control with Cutoff Wall
- Source Control with *In-Situ* Chemical Treatment (permeable reactive barrier [PRB])

Based on the CMA, three corrective measures, including source control with GWP, source control with cutoff wall, and source control with ISS[2], were identified as potentially viable corrective measures for the WAPS. The source control with cutoff wall remedy considered by the CMA was expanded into source control with CCS, which extends the cutoff wall to the competent bedrock and integrates it into the previously implemented final cover.

Of these corrective measures, source control with GWP and source control with CCS were selected for further evaluation, design advancement, and comparative assessment within the CAAA for the WAPS.

2.1.1 Corrective Action Alternatives Analysis Supporting Information Report

The CAAA for the WAPS was prepared by Gradient based on a CAAA-SIR prepared by Ramboll. The CAAA-SIR, which is included as Attachment B of the CAAA provided in **Appendix A**, included additional evaluation, design advancement, and comparative assessment of the source control with GWP and source control with CCS corrective measures identified as potentially viable for the WAPS. The evaluation included the completion of feasibility-level design activities for each alternative and incorporated the following tasks:

- Performing predictive groundwater modeling to evaluate the scope (*i.e.,* location and extents) of each alternative and the corresponding estimated time to achieve GWPS;
- Developing feasibility-level design drawings showing the extent in plan and elevation view of each engineered remedy;

[2] The source control with ISS remedy was evaluated further at a preliminary level and determined to be infeasible, as discussed in the CAAA provided in **Appendix A**.

- Estimating the time required to design, construct, and implement each remedy, in addition to ongoing operational and maintenance requirements;
- Identifying future tasks required to implement each alternative, including permitting, investigation, and design efforts; and
- Estimating relevant material quantities, labor hours, delivery miles, equipment miles, and daily commuting miles associated with constructing each remedy.

2.1.2 Corrective Action Alternatives Analysis

The CAAA (**Appendix A**) included a detailed analysis of each of the corrective action alternatives presented in the CAAA-SIR, including an evaluation of:

- Long- and short-term effectiveness and protectiveness;
- Ease or difficulty of implementation;
- Degree to which community concerns are addressed; and
- Relative amount of contamination removed from the environment.

Based on the CAAA, source control with CCS was identified as the most appropriate corrective action for the WAPS and was selected for further design development as part of this CAP.

It should be noted that the permit-level engineering assessments, groundwater modeling, and other information contained within this CAP were developed to a higher level of design and detail than for the source control with CCS within the CAAA; therefore, information on items such as permitting, remedy scope, estimated time to reach GWPS, implementation schedule, etc. may differ between this CAP and the information included in the CAAA-SIR and CAAA. Information for the source control with CCS contained within the CAP should be considered to supersede information contained within the CAAA and CAAA-SIR.

3. CORRECTIVE ACTION PLAN

The 35 I.A.C. § 845 requirements for the CAP and corresponding demonstrations that the proposed corrective measures meet these requirements are discussed individually in this section. Many of the CAP requirements are discussed within the CMA and CAAA documents that have been prepared to support the CAP. Therefore, the demonstrations will also refer to those documents.

3.1 General Requirements

35 I.A.C. § 845.670(c): The corrective action plan must meet the following requirements:

(1) Be based on the results of the corrective measures assessment conducted under 35 I.A.C. § 845.660;

(2) Identify a selected remedy that at a minimum, meets the standards listed in subsection (d);

(3) Contain the corrective action alternatives analysis specified in subsection (e); and

(4) Contain proposed schedules for implementation, including an analysis of the factors in subsection (f).

This CAP is based on the results of the CMA and CAAA, which are included within **Appendix A**. The proposed schedule for implementing source control with CCS is provided in **Table 2**.

3.2 Remedy Selection

35 I.A.C. § 845.670(d): The selected remedy in the corrective action plan must:

(1) Be protective of human health and the environment;

Current conditions at the WAPS pose no risk to human health or environment (**Appendix A**). Concentrations of CCR-derived constituents are anticipated to continue to decline with the final cover that is in place, even without implementation of the DCW component of CCS. Once the DCW is installed, CCR within the WAPS would be contained within a continuous system of low-permeability materials and isolated from the surrounding environment on all sides.

(2) Attain the groundwater protection standards specified in 35 I.A.C. § 845.600;

Groundwater modeling used to support the design of the DCW (Appendix B of the CAAA-SIR) indicates the selected remedy of source control with CCS will attain the GWPS in approximately 33 years after complete implementation.

(3) Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in 35 I.A.C. § 845.600 into the environment;

The CCS will result in CCR within the WAPS being contained by a continuous system of low-permeability material on all sides of the WAPS. This includes the final cover system as surface containment, the DCW as lateral containment, and low-permeability competent bedrock as base containment beneath the CCR. This CCS would reduce, to the maximum extent feasible, further releases of constituents listed in 35 I.A.C. § 845.600 from the WAPS into the environment.

(4) Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, taking into account factors such as avoiding inappropriate disturbance of sensitive ecosystems; and

No known releases of CCR due to a structural integrity issue have occurred at the WAPS.

(5) Comply with standards for management of wastes as specified in 35 I.A.C. § 845.680(d).

The CCR managed during construction of the selected remedy (source control with CCS) will be done in accordance with all 35 I.A.C. § 845 requirements and the submitted closure plan [14].

3.3 Schedule for Implementation

The CCS is an effective engineered control as it provides hydraulic isolation at the limits of the WAPS and has been demonstrated as a reliable remedy by the USEPA [15]. The CCS will provide permanent hydraulic isolation of CCR within the WAPS from the surrounding environment. The CCS will remain in-place and functional even after GWPS have been met.

The CCS remedy was evaluated to determine if the DCW component of CCS can be successfully implemented to achieve GWPS compliance in a timely manner. Timeframes to attain GWPS in the corrective action monitoring network wells are estimated in **Table A**:

Table A. Estimated Timeframes to Attain GWPS in Groundwater Monitoring Wells

	2 years‡	5 years‡	10 years‡	20 years‡	33 years‡
Percentage of wells predicted to attain GWPS†	67%	67%	67%	89%	100%

†: Nine wells were used to estimate time to reach GWPS in the 2025 Groundwater Modeling Technical Memorandum.
‡: Years counted starting from 2028, presumed completion of implementation of DCW portion of CCS.

35 I.A.C. § 845.670(f): The owner or operator must specify, as part of the corrective action plan, a schedule for implementing, of and completing, remedial activities. The schedule must require the completion of remedial activities within a reasonable time, taking into consideration the factors in this subsection (f). The owner or operator of the CCR surface impoundment must consider the following factors in determining the schedule of remedial activities:

The schedule for implementation and completion of the DCW component of the CCS remedy at the WAPS is included in **Table 2**. Implementation of the remedy will occur within 90 days of approval of the CAP, in accordance with 35 I.A.C. § 845.680(a)(1).

The schedule was developed considering the factors required by 35 I.A.C. §§ 845.670(f)(1) through (5), as summarized below.

35 I.A.C. § 845.670(f)(1): Extent and nature of contamination, as determined by the characterization required under 35 I.A.C. § 845.650(d);

The Nature and Extent Report [16], which was submitted to the IEPA on May 8, 2024 and is included as an attachment to the CAAA (**Appendix A)**, details exceedances of GWPS. Groundwater modeling and geochemical analysis were performed by Ramboll as part of the CAAA-SIR to design the remedy, and the modeling considered the nature and extent of contamination.

35 I.A.C. § 845.670(f)(2): Reasonable probabilities of remedial technologies achieving compliance with the GWPS established by 35 I.A.C. § 845.600 and other objectives of the remedy;

Several remedies were evaluated in the CAAA (**Appendix A**), and results of groundwater modeling indicated that the selected remedy (source control with CCS) is expected to achieve compliance with 35 I.A.C. § 845.600. Groundwater modeling was performed to evaluate future groundwater quality in the vicinity of the WAPS. The results of the modeling indicate that groundwater will attain the GWPS for all constituents identified as having potential exceedances in the primary migration pathway (the uppermost aquifer [UA] groundwater unit) within approximately 33 years. As documented in the Groundwater Polishing Evaluation Report attached to the CAAA (**Appendix A**), attenuation of COCs, boron, lithium, sulfate, and TDS through sorption and chemical mechanisms will complement results of the groundwater transport modeling, in that time to reach GWPS may be shorter than the simulated timeframes. Remobilization of arsenic, which exceeds GWPS at two wells (51 and 21R), may increase the time to reach GWPS from the simulated results.

35 I.A.C. § 845.670(f)(3): Availability of treatment or disposal capacity for CCR managed during implementation of the remedy;

Excavated soils (*e.g.,* spoils) are expected to primarily be non-CCR material and will be placed into off-road dump trucks and disposed of in the East Ash Pond (EAP) as contouring fill to support EAP closure in accordance with the submitted closure plan [14]. The EAP is expected to have sufficient disposal capacity for CCR wastes generated during remedy construction. After construction, the DCW component of CCS is not anticipated to result in the management of an appreciable volume of CCR.

35 I.A.C. § 845.670(f)(4): Potential risks to human health and the environment from exposure to contamination before completion of the remedy;

A Human Health and Ecological Risk Assessment was completed and included as an attachment to the CAAA (**Appendix A**). The overall conclusion is that groundwater from the WAPS impoundments and potential COC concentrations in groundwater contributions to surface water and sediment in the Illinois River pose no unacceptable risks to human health or the environment. However, the CAAA indicated that short-term negative impacts on surface water and sediment quality immediately adjacent to the site due to erosion and runoff from construction activities could occur but will be mitigated using stormwater best management practices (BMP) in accordance with applicable land disturbance permit requirements.

This conclusion is based on modeled and detected maximum concentrations of all COCs in surface water and sediment in the Illinois River, which were below conservative risk-based screening benchmarks. This conclusion was reached using methodology consistent with applicable USEPA risk assessment principles. The assessment relied on conservative assumptions meant to overestimate possible exposures and risks and provide an additional level of certainty in the conclusions.

35 I.A.C. § 845.670(f)(5): Resource value of the aquifer, including:

The resource value of the aquifer is discussed in the Hydrogeologic Site Characterization Report (HCR), which is included as Appendix B to the closure CP Application [11]. The HCR addresses paragraphs (A) through (F) from 35 I.A.C. § 845.670(f)(5), as summarized below.

35 I.A.C. § 845.670(f)(5)(A): Current and future uses, including potential residential, agricultural, commercial industrial and ecological uses;

Current uses and users of the groundwater are discussed in the HCR Section 3.5 and Appendix F. A water well inventory was completed in 2009 utilizing federal and state databases to assess nearby pumping wells, drinking water receptors, and other uses of water in the vicinity of the HEN property boundary inclusive of WAPS. Based on records obtained from IEPA, Illinois State Geological Survey (ISGS), and Illinois State Water Survey (ISWS), there are 2 wells located within 2,500 meters of WAPS. The two wells were reportedly constructed in 1844 and 1922 according to State of Illinois records that have been verified and were most likely abandoned decades ago [11]. There are no public water system (PWS), community water supply (CWS) or non-CWS wells, or wellhead protection areas (WHPAs) within 2,500 feet of WAPS. There are four wells owned by DMG within the HPP property boundary all of which are non-potable and non-contact industrial wells.

35 I.A.C. § 845.670(f)(5)(B): Proximity and withdrawal rate of users;

See preceding discussion on 35 I.A.C. § 845.670(f)(5)(B) for a discussion on the proximity and withdrawal rates of users.

35 I.A.C. § 845.670(f)(5)(C): Groundwater quantity and quality;

Per 35 I.A.C. § 620.210, groundwater within the UA at the WAPS meets the definition of Class I – Potable Resource Groundwater. The Human Health and Ecological Risk Assessment (Appendix A in CAAA) concluded that groundwater from the WAPS impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment.

35 I.A.C. § 845.670(f)(5)(D): The potential impact to the subsurface ecosystem, wildlife, other natural resources, crops, vegetation, and physical structures caused by exposure to CCR constituents;

Potential surface receptors are discussed in the HCR for HPP East Ash Pond Sections 3.5 [17]. A survey to identify surface water features, nature preserves, and historic sites was conducted for a 1,000-meter radius around the WAPS. Section 3.5.1 of the Human Health and Ecological Risk Assessment included as Appendix A of the CAAA Report stated there are no current unacceptable risks to ecological receptors at the WAPS.

35 I.A.C. § 845.670(f)(5)(E): The hydrogeologic characteristic of the facility and surrounding land; and

The hydrogeological assessment identified that the stratigraphy within and immediately surrounding the WAPS consists of fill, unlithified river alluvium, and Pleistocene-age glacial outwash deposits overlying Pennsylvanian-age shale bedrock. Where undisturbed or partially excavated, the native surficial soil at the site is poorly drained, moderately permeable silty clay loam formed as alluvium in floodplains.

There are two hydrostratigraphic units:

- **Uppermost Aquifer (UA)**: Includes the unlithified natural geologic materials of the Cahokia Alluvium and Henry Formation extending from the upper saturated zone to the bedrock. The UA contains variable amounts of cobbles and boulders within a sand and gravel matrix. Both the prevalence and size of the cobbles and boulders increase with depth.

- **Bedrock Confining Unit**: Comprised of shales with thin limestone, sandstone, and coal beds. This bedrock confining unit is encountered at elevations ranging from 374.3 to 410.2 feet.[3]

35 I.A.C. § 845.670(f)(5)(F): The availability of alternative water supplies.

As discussed in subsection A, there are no extraction wells within 2,500 meters of the site. Therefore, an alternate water supply is not necessary.

3.3.1 Other Relevant Factors

35 I.A.C. § 845.670(f)(6): Other relevant factors.

No additional factors were identified for consideration.

3.4 Necessity of Interim Measures

Source control using the consolidate-and-cap approach has been completed [1, 2] and shown to be effective at remediating groundwater. Completion of DCW portion of CCS is projected to be complete within five to seven years after approval of the CAP. Source control followed by GWP alone was predicted by the groundwater supporting the closure plan would result in the decrease in CCR constituent concentrations in groundwater, and a contraction of the groundwater contaminant plume [6]. The prediction of the groundwater model is further supported by decreases in boron concentrations at a number of wells within the monitoring network upon closure. Therefore, no interim measure is required. Further, all subsections of this requirement are discussed as follows.

35 I.A.C. § 845.680(a)(3)(A): Time required to develop and implement a final remedy.

The final cover portion of the CCS remedy (source control) was implemented at the site in 2020 utilizing a consolidation and cap final closure approach [1, 2]. As presented in the Groundwater Modeling Technical Memorandum, source control alone is predicted to achieve the GWPS in approximately 30 years. The DCW portion of the CCS remedy is supplemental to the current source control. Implementation of the DCW portion of the CCS is anticipated to take up to seven years following approval of the CAP. Therefore, no interim measures are required as the primary corrective action has already been implemented.

35 I.A.C. § 845.680(a)(3)(B): Actual or potential exposure of nearby populations or environmental receptors to any of the constituents listed in 35 I.A.C. § 845.600.

There are no current unacceptable risks to human or ecological receptors at the site (**Appendix A**). It was concluded the UA was not a source of drinking water [11].

35 I.A.C. § 845.680(a)(3)(C): Actual or potential contamination of sensitive ecosystems or current or potential drinking water supplies.

The nature and extent of exceedances have been evaluated in the Nature and Extent Report [16]. Although there are exceedances of GWPS, there are no impacts to current or potential drinking water supplies. As stated above, there are no current unacceptable risks to human or ecological receptors at the site.

[3] All elevations in this report are in the North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

35 I.A.C. § 845.680(a)(3)(D): Further degradation of the groundwater that may occur if remedial action is not initiated expeditiously.

The final cover portion of the CCS remedy (source control) was implemented at the site in 2020 utilizing a consolidation and cap final closure approach [1, 2], and corresponding decreases in boron concentrations have already been observed. No additional interim measures are needed to prevent further degradation of the groundwater more expeditiously than implementation of the selected remedy.

35 I.A.C. § 845.680(a)(3)(E): Weather conditions that may cause any of the constituents listed in 35 I.A.C. § 845.600 to migrate or be released.

As stated above, the final cover portion of the CCS was implemented in 2020 and provides surface containment that isolates CCR within the WAPS from typical site weather conditions.

35 I.A.C. § 845.680(a)(3)(F): Potential for exposure to any of the constituents listed in 35 I.A.C. § 845.600 as a result of accident or failure of a container or handling system.

The WAPS is closed-in-place within a consolidated footprint, therefore no container or handling systems are currently in use, nor will they be in use in the future.

35 I.A.C. § 845.680(a)(3)(G): *Other situations that may pose threats to human health and the environment.*

No situations have been identified where WAPS CCR leachate poses threats to human health and environment.

Table 2. Proposed Milestone Schedule for Implementing Corrective Action Remedy (Source Control with Continuous Containment System)

Implementation Phase	Implementation Task	Timeframe (Preliminary Estimates)
1: Pre-Construction Activities	Agency Coordination, Approvals, and Permitting	18 to 24 months
	Final Design and Bid Process	24 to 36 months
	Timeframe to Complete Corrective Pre-Construction Activities	42 to 60 months after CAP Approval
2: Corrective Action Construction	Corrective Action Construction	18 to 24 months
	Timeframe to Complete Corrective Action Construction	18 to 24 months
3: Corrective Action Monitoring and Closeout	Corrective Action Monitoring (Time to Meet GWPS)	396 months (33 years)
	Corrective Action Groundwater Confirmation Monitoring	36 months
	Corrective Action Completion	6 months
	Timeframe to Complete Corrective Action O&M and Closeout	438 months
Total Timeline to Complete Corrective Action (after approval of CAP)		498 to 522 months (42 to 44 years)

[1]All timeframes are preliminary and may change as the project develops. Timeframes may also be affected by regulatory review and/or permit approval processes, for both 35 I.A.C. § 845 and non-35 I.A.C. § 845 permits.

Summary of Findings

Title 35, Part 845 of the Illinois Administrative Code (IAC) (IEPA, 2021) requires that a Corrective Action Alternatives Analysis (CAAA) be performed as part of the remedy selection, prior to undertaking any corrective actions at certain coal combustion residual (CCR)-containing impoundments, where exceedances of groundwater protection standards (GWPSs) have been identified. This report presents a CAAA for the West Ash Pond System (WAPS) at the Hennepin Power Plant (HPP) pursuant to the requirements under IAC Section 845.670. The goal of performing a CAAA is to holistically evaluate the potentially viable corrective actions identified in the Corrective Measures Assessment (CMA) (Appendix C; Ramboll, 2024a) in order to remediate groundwater and achieve compliance with the groundwater protection standards (GWPSs) specified under IAC Section 845.600 (IEPA, 2021). These analyses assess potentially viable corrective action alternatives based on a wide range of factors, including the efficiency, reliability, and ease of implementation of a corrective action; its potential positive and negative short- and long-term impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021).

It is important to note that many CCR sites are complex groundwater environments where remedial actions will inherently take many years to complete. While no formal definition of a complex groundwater environment exists, most would agree that there are a number of common characteristics at complex groundwater sites, including the following (National Research Council, 2013):

- Highly heterogeneous subsurface environments;
- Large source zones;
- Multiple, recalcitrant constituents; and
- Long timeframes over which releases occurred.

Each of these characteristics are common at CCR sites. Surface impoundments are often tens to hundreds of acres in size and many have operated for decades, leading to large source zones and prolonged releases. Furthermore, CCR impoundments are often located in alluvial geologic settings where sands are interbedded with silts and clays. This results in a heterogeneous environment where constituent mass may persist for many years in low-permeability deposits. Finally, the constituents that are most common at CCR sites include metals and inorganics that do not naturally biodegrade. The combination of these factors results in a complex groundwater environment where remediation, even under the best of circumstances, may take many years to achieve GWPSs. It is for these reasons that the United States Environmental Protection Agency (US EPA) refused to specify what is a reasonable *vs.* an unreasonable timeframe for groundwater corrective actions at CCR sites, stating that it "was truly unable to establish an outer limit on the necessary timeframes – including even a presumptive outer bound" (US EPA, 2015a).

In this CAAA, all corrective actions that have been evaluated consist of source control and residual plume management. Source control is generally considered to be one of the more effective remedial action approaches. Source control involves removing the hydraulic head from an impoundment (*i.e.*, unwatering and dewatering) and preventing further downward migration of constituents. US EPA has found that "releases from surface impoundments [to groundwater] drop dramatically after closure" (US EPA, 2014, pp. 5-18 to 5-19). US EPA has also stated that source control is the most effective means of ensuring the

timely attainment of remediation objectives (US EPA, 2015b). As a result, the implementation of source control often has a substantial and immediate effect on groundwater quality improvements.

The specific source control method that is the central component of all the corrective action alternatives evaluated in this CAAA is closure-in-place (CIP) using a consolidate-and-cap approach for the WAPS, which was approved of by IEPA in 2018 and completed in 2020 (Buscher, 2018; Tickner, 2020a,b). The WAPS consists of two sub-units, specifically, the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). The source control included dewatering of coal combustion residuals (CCRs), excavation and consolidation of material from the OWPP into the OWAP, followed by the installation of an impermeable cap on the OWAP. Closure activities specifically included removal of impounded water and excavation of CCR and one foot of soil below the CCR from the OWPP, construction of a sheet pile wall and compacted clay buttress to separate the OWAP from the OWPP, and installation of a final cover system over the OWAP consisting of a geosynthetic layer, a protective soil layer to limit infiltration of precipitation into the impoundment, and establishment of a vegetative cover. These activities were designed to control, minimize or eliminate, post closure infiltration of liquids into the impounded CCR. As demonstrated by groundwater modeling in support of the Closure and Post-Closure Care Plan and this CAAA (Geosyntec Consultants, Inc., 2017; Appendix B; Ramboll, 2025a), the hydraulic pressure beneath the final cover system would drop to "near-zero levels" within 7 years after closure and cause constituent concentrations in groundwater to decrease and the groundwater plume to contract (Geosyntec Consultants, Inc., 2017). Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS would also be controlled and minimized.

Two potential corrective actions are evaluated in this CAAA: Source Control with Groundwater Polishing (Source Control-GWP) and Source Control with a Continuous Containment System (Source Control-CCS). Both alternatives consist of source control and residual plume management; residual plume management for the two remedial approaches are groundwater polishing and a continuous containment system. Both alternatives were identified as viable approaches in the CMA (Appendix C; Ramboll, 2024a). It should be noted that Source Control-GWP, Source Control with a Cutoff Wall, and Source Control-ISS (Source Control with *In-Situ* Stabilization [ISS]) were identified in the CMA as viable remedial approaches (Appendix C; Ramboll, 2024a). However, during subsequent evaluations, the remedial approaches were modified. Remedy modifications include the following:

- Source Control-ISS was determined infeasible and excluded for further evaluation due to significant potential risks, including the need to temporarily remove half of the previously installed WAPS final cover. Removal of the final cover system would result in significant stormwater infiltration and potentially lead to reducing the effectiveness of the completed source control. In addition, ISS would involve managing tens of thousands of cubic yards of CCR and CCR-impacted cuttings on the WAPS surface, increasing the risk of releasing CCR-contaminated stormwater and sediments during construction, which could negatively impact nearby sensitive areas.
- Source Control-Cutoff Wall was expanded into the Source Control-CCS alternative, which is evaluated in this report. The continuous containment system (CCS) integrates the cutoff wall with the existing final cover to provide full lateral and surface isolation of CCR from the surrounding environment. The wall would be keyed into competent shale bedrock to provide additional base subsurface containment below the WAPS.

Under the Source Control-GWP alternative, active groundwater monitoring would supplement source control to verify and document the attenuation by natural physical and geochemical mechanisms of constituent concentrations in groundwater. Site-specific evaluations demonstrated that groundwater polishing is appropriate at the WAPS because Site conditions are favorable for natural attenuation of

inorganic contaminants *via* adsorption and precipitation. However, it should be noted that some arsenic[1] re-mobilization may occur as groundwater returns to background conditions (Appendix E; Geosyntec Consultants, Inc., 2025). Under the Source Control-CCS alternative, the final cover system would be temporarily removed in the areas where the cutoff wall would be installed. An approximately 90 ft deep cutoff wall consisting of low-permeability material (either a mixture of soil and bentonite or cement and bentonite) would be constructed, extending from the top of the WAPS perimeter dikes completely through the Uppermost Aquifer (UA) and penetrate into the underlying competent shale bedrock. The final cover system would be extended across the top of the cutoff wall after installation. The final cover, the cutoff wall, and the competent shale bedrock would enclose the OWAP, which is the portion of the WAPS that was closed by CIP, resulting in CCR being contained within a continuous containment system, and would isolate CCR from the surrounding environment on all sides (Appendix B; Ramboll, 2025a).

Table S.1 evaluates the two potentially viable corrective actions evaluated in this CAAA (Source Control-GWP and Source Control-CCS) with regard to each of the factors specified under IAC Section 845.670(d) and IAC Section 845.670(e) (IEPA, 2021). Based on this evaluation and the details provided in Section 2 of this report, the most appropriate corrective action for this Site is Source Control-CCS. Although the expected impacts on workers, nearby communities, and the environment under the Source Control-GWP alternative are lower than the Source Control-CCS alternative, the Source Control-CCS alternative would provide full containment of the CCR within WAPS and be more effective at controlling sources of releases than Source Control-GWP. Controlling the source of releases using CCS is particularly important at this Site because of the high groundwater transmissivity associated with the sands and gravels in the UA. Thus, Source Control-CCS is the most appropriate corrective action alternative for the WAPS.

[1] It should be noted that not all arsenic in groundwater is associated with the WAPS. Some of the arsenic is likely naturally occurring and/or associated with other sources.

Table S.1 Comparison of Proposed Corrective Action Alternatives with Respect to Factors Specified in IAC Section 845.670(d) and IAC Section 845.670(e)

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
Magnitude of Reduction of Existing Risks/Be Protective of Human Health and the Environment (Section 2.2.1; IAC Section 845.670(e)(1)(A)/ IAC Section 845.670(d)(1))	Because current conditions do not present a risk to human health or the environment at the WAPS, there will be no unacceptable risk to human health or the environment for future conditions since the unit was closed and source control was implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. The magnitude of the reduction of existing risks is the same for all of the potential corrective action alternatives, and both corrective action alternatives are equally protective of human health and the environment.	Because current conditions do not present a risk to human health or the environment at the WAPS, there will be no unacceptable risk to human health or the environment for future conditions since the unit was closed and source control was implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. The magnitude of the reduction of existing risks is the same for all of the potential corrective action alternatives, and both corrective action alternatives are equally protective of human health and the environment.
Effectiveness of the Remedy in Controlling the Source (Section 2.2.2; IAC Section 845.670(e)(2))		
Extent to Which Containment Practices Will Reduce Further Releases/Control the Sources of Releases to Reduce or Eliminate, to the Maximum Extent Feasible (IAC Section 845.670(e)(2)(A)/ IAC Section 845.670(d)(3))	Both alternatives include source control (which is the primary remedial measure) and residual plume management. Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Modeling results in support of the Closure Plan indicated that source control would result in a significant reduction in groundwater concentrations and, overtime, reduce the extent of groundwater impacts to within the footprint of the impoundment (Geosyntec Consultants, Inc., 2017). Under residual plume management for this alternative, physical and geochemical attenuation mechanisms would mitigate impacts to downgradient groundwater quality and control the residual plume. However, it should be noted that some arsenic re-mobilization may occur as groundwater returns to background conditions, which may cause an impact to the time	Both alternatives include source control (which is the primary remedial measure) and residual plume management. Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Modeling results in support of the Closure Plan indicated that source control would result in a significant reduction in groundwater concentrations and, overtime, reduce the extent of groundwater impacts to within the footprint of the impoundment (Geosyntec Consultants, Inc., 2017). Under residual plume management for this alternative, a cutoff wall would be constructed and incorporated into the existing final WAPS cover system. This would create a continuous low-permeability barrier that fully contains the CCR within the WAPS. This system ensures isolation from the surrounding environment through lateral containment by the deep cutoff wall,

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	required to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025). If necessary, remedy optimizations would be implemented under the adaptive site management program.	surface containment by the existing geomembrane cover, and a natural barrier provided by the competent shale bedrock below. Thus, this subsurface barrier will isolate the CCR from the surrounding environment and will control the sources of releases to the environment. If necessary, remedy optimizations would be implemented under the adaptive site management program. Source Control-CCS would be more effective at controlling releases than Source Control-GWP. CCS would isolate CCR from the surrounding environment on all sides and in particular would prevent releases of CCR-related constituents associated with the high groundwater transmissivity of the sand and gravel deposits in the UA.
Extent to Which Treatment Technologies May Be Used (IAC Section 845.670(e)(2)(B))	Source Control-GWP would rely on physical and geochemical attenuation processes. If necessary, remedy optimizations would be implemented under the adaptive site management program.	The Source Control-CCS alternative would utilize an engineered physical barrier to contain the CCR within WAPS. Contact stormwater may be generated during the construction phase, which would be pumped to the on-Site treatment pond before discharging *via* an NPDES permitted outfall. No additional treatment technologies would be required once the cutoff wall has been constructed. If necessary, remedy optimizations would be implemented under the adaptive site management program.
Likelihood of Future Releases of CCR (Section 2.2.3; IAC Section 845.670(e)(1)(B))	Both corrective action alternatives include source control using CIP with a consolidate-and-cap approach; the CIP source control was completed in in 2020 in compliance with 40 CFR Part 257, Subpart D. This included a geosynthetic layer, a protective soil layer to limit infiltration, and a vegetative cover. This cover system provides increased protection against berm and surface erosion, precipitation infiltration, and other adverse effects that could potentially trigger a release of CCR. Thus, there is minimal risk of	Both corrective action alternatives include source control using CIP with a consolidate-and-cap approach; the CIP source control was completed in in 2020 in compliance with 40 CFR Part 257, Subpart D. This cover system provides increased protection against berm and surface erosion, precipitation infiltration, and other adverse effects that could potentially trigger a release of CCR. Any CCR-contact stormwater

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	accidental CCR releases occurring post-closure under either of the alternatives.	generated during the construction phase would be managed through a contact stormwater management system. Thus, there would be minimal risk of accidental CCR releases occurring post-closure under either of the alternatives.
Type and Degree of Long-Term Management, Including Monitoring, Operation, and Maintenance (Section 2.2.4; IAC Section 845.670(e)(1)(C))	Minimal long-term O&M efforts would be required under Source Control-GWP because it would not require the installation, operation, or maintenance of any engineered systems or structures other than maintenance of the monitoring wells. Corrective action groundwater monitoring would continue until GWPSs have been achieved. Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section 845.780(c). Additionally, corrective action groundwater monitoring would continue for 3 years after GWPS have been achieved. Based on the adaptive site management approach, remedy optimizations might be implemented to ensure achievement of the GWPSs.	Residual plume management for the Source Control-CCS alternative would require construction of a deep cutoff wall that would occur in three phases. Once the cutoff wall has been installed, no O&M efforts would be required, because it is a passive and below-grade structure. However, post-construction quality assurance (QA) programs may be required to validate the quality of the constructed cutoff wall. Corrective action groundwater sampling would continue until GWPSs have been achieved. Post-closure care groundwater monitoring will continue for a minimum of 30 years as required by IAC Section. 845.780(c). Additionally, corrective action groundwater monitoring would continue for 3 years after GWPS have been achieved. Based on the adaptive site management approach, remedy optimizations may be implemented to ensure achievement of the GWPSs.
Short-Term Risks to the Community or the Environment During Implementation of Remedy (Section 2.2.5; IAC Section 845.670(e)(1)(D))		
Safety Impacts	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there is no further risk of accidents and injuries occurring during the implementation of the source control remedy. Overall, no worker accidents or injuries would be expected under the Source Control-GWP alternative because no installation, operation, and	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there is no further risk of accidents and injuries occurring during the implementation of the source control remedy. Overall, considering worker accidents occurring during residual plume management both on- and off-Site, 0.65 worker injuries and 0.013 worker

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	maintenance of engineered systems or structures would be required. Similarly, no off-Site impacts on nearby residents would be expected under the Source Control-GWP alternative.	fatalities would be expected under the Source Control-Cutoff Wall alternative. In total, an estimated 0.21 injuries and 2.5×10^{-3} fatalities would be expected to occur among community members due to off-Site activities under the Source Control-CCS alternative.
Cross-Media Impacts to Air	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. No further air impacts associated with the implementation of the source control remedy are expected. Cross-media impacts to air associated with residual plume management can result from the emission of air pollutants and greenhouse gases (GHGs) from construction vehicles and equipment. These emissions are proportional to the use of construction vehicles and equipment that are required for residual plume management. Residual plume management for the Source Control-GWP alternative would be expected to have minimal air impacts, because it would not require the construction of any engineered systems or structures.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. No further air impacts associated with the implementation of the source control remedy are expected. Cross-media impacts to air associated with residual plume management can result from the emission of air pollutants and GHGs from construction vehicles and equipment. These emissions are proportional to the use of construction vehicles and equipment that are required for residual plume management. Residual plume management for the Source Control-CCS alternative would have greater air impacts than the Source Control-GWP alternative due to the increased construction activity required for this alternative.
Cross-Media Impacts to Surface Water and Sediments	Source control was implemented in 2020 for both corrective action alternatives, and constituent mass flux from groundwater into surface water will decline over time (Geosyntec Consultants, Inc., 2017). The source control approach minimizes the amount of water retained within the impoundment, which reduces the hydraulic flux through the CCR. Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS will also be controlled or minimized. As demonstrated by the groundwater modeling in support of the Closure Plan, source control would result in a significant reduction in groundwater concentrations and, overtime, reduce the extent of groundwater impacts to within the	Source control was implemented in 2020 for both corrective action alternatives, and constituent mass flux from groundwater into surface water will decline over time (Geosyntec Consultants, Inc., 2017). Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS will also be controlled or minimized. As demonstrated by the groundwater modeling in support of the Closure Plan, source control would result in a significant reduction in groundwater concentrations and, overtime, reduce the extent of groundwater impacts to within the

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	footprint of the impoundment (Geosyntec Consultants, Inc., 2017). Under residual plume management for the Source Control-GWP alternative, minimal surface water and sediment impacts would be expected, because it would not require the construction of any engineered systems or structures.	footprint of the impoundment (Geosyntec Consultants, Inc., 2017). Under residual plume management for the Source Control-CCS alternative, surface water and sediment impacts would be higher than the Source Control-GWP alternative due to the construction of the cutoff wall. Any associated impacts would be addressed through best management practices (BMPs) in accordance with Site land disturbance permits.
Control of Exposure to Any Residual Contamination During Implementation of the Remedy	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further risks of CCR exposure associated with source control implementation. Risks to workers arising from potential contact with residual contamination during construction activities associated with residual plume management would be minimal under the Source Control-GWP alternative, which would not involve exposure to soil or groundwater waste streams.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further risks of CCR exposure associated with source control implementation. Risks to workers arising from potential contact with residual contamination during construction activities associated with residual plume management would be higher for the Source Control-CCS alternative than for the Source Control-GWP alternative because the Source Control-CCS alternative would involve removal of a portion of the previously installed final cover system and excavation and subsequent disposal of Site spoils. Any potential CCR-exposures during the Source Control-CCS alternative would be managed through the use of rigorous safety protocols and personal protective equipment.
Other Identified Impacts	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further impacts associated with the implementation of source control. The energy demands of construction equipment and vehicles associated with residual plume management would be lower under the Source Control-GWP alternative, because this alternative	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further impacts associated with the implementation of source control. The energy demands of construction equipment and vehicles associated with residual plume management would be greater under the Source Control-CCS compared to the Source Control-GWP alternative, because the Source Control-

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	would not require any significant construction activity. Similarly, traffic and noise impacts associated with residual plume management are expected to be minimal because no installation, operation, and maintenance of engineered systems or structures would be required. There would be no impacts to natural resources and habitat under the Source Control-GWP alternative because no additional construction activities would be required.	CCS alternative would involve the construction of the barrier wall. Similarly, traffic and noise impacts associated with residual plume management are expected to be higher under the Source Control-CCS alternative than the Source Control-GWP alternative due to the construction activities that would be required to construct the cutoff wall. Under the Source Control-CCS alternative, some negative impacts on scenic and recreational value may occur along the Illinois River and within the Donnelley/DePue State Fish and Wildlife Areas complex, which borders the Site to the north and west. Given the proximity between these areas and the expected construction, it is likely that these areas would experience some adverse impacts such as visual disturbance, obstruction of view, and noise during the construction period. However, these impacts are expected to diminish once the construction is completed in 18 to 24 months. In addition, the construction of the cutoff wall under the Source Control-CCS alternative is expected to use a significant amount of cement or bentonite, which would be introduced into the UA and BCU. Adding substantial quantities of these materials into the subsurface environment may cause alteration in groundwater pH levels and affect geochemical conditions in the UA.
Time Until Groundwater Protection Standards Are Achieved/Attain the Groundwater Protection Standards Specified in Section 845.600 (Section 2.2.6; IAC Section 845.670(e)(1)(E); IAC Section 845.670(d)(2))	Groundwater modeling was performed in support of the Closure Plan (Geosyntec Consultants, Inc., 2017). The modeling predicted that source control would result in the reduction of leachate production, which facilitates the contraction of the contaminant plume in groundwater (Geosyntec Consultants, Inc., 2017).	Groundwater modeling was performed in support of the Closure Plan (Geosyntec Consultants, Inc., 2017). The modeling predicted that source control would result in the reduction of leachate production, which facilitates the contraction of the contaminant plume in groundwater (Geosyntec Consultants, Inc., 2017).

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	Additional modeling was conducted for each of the corrective action alternatives to evaluate future groundwater quality in the vicinity of the WAPS as a result of residual plume management (Appendix B; Ramboll, 2025b). The results of the modeling indicate that groundwater would attain the GWPSs for all of the constituents identified as having potential groundwater exceedances in the monitoring network within 29 years after approval of the Corrective Action Plan when the Source Control-GWP alternative is presumed to be initiated (Appendix B; Ramboll, 2025a).	Additional modeling was conducted for each of the corrective action alternatives to evaluate future groundwater quality in the vicinity of the WAPS as a result of residual plume management (Appendix B; Ramboll, 2025b). The results of the modeling indicate that groundwater would attain the GWPSs for all of the constituents identified as having potential groundwater exceedances in the monitoring network within 38 to 40 years (5 to 7 years of pre-construction and construction activities and 33 years after installation) after approval of the Corrective Action Plan when the Source Control-CCS alternative is presumed to be initiated (Appendix B; Ramboll, 2025a).
Potential for Exposure of Humans and Environmental Receptors to Remaining Wastes, Considering the Potential Threat to Human Health and the Environment Associated with Excavation, Transportation, Re-disposal, Containment, or Changes in Groundwater Flow (Section 2.2.7; IAC Section 845.670(e)(1)(F))	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Therefore, both corrective action alternatives are equally and fully protective with regard to exposure to residual CCR. As a result of the source control, there would be no risk of CCR releases post-closure. The Source Control-GWP alternative would not involve exposure to the soil or groundwater waste streams and thus, there is no potential for exposure of humans and environmental receptors to wastes.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Therefore, both corrective action alternatives are equally and fully protective with regard to exposure to residual CCR. As a result of the source control, there would be no risk of CCR releases post-closure. For construction workers, risks arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be higher for the Source Control-CCS than for the Source Control-GWP alternative, because the Source Control-CCS alternative would involve the excavation and subsequent management of Site soils. In addition, Source Control-CCS would involve temporarily removing a portion of the final cover previously installed, which could potentially allow stormwater to be in contact with CCR material during construction. CCR-contact stormwater would be generated and managed through a CCR-contact stormwater management system during the times when the final cover would be removed.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
		Any potential CCR exposures occurring under Source Control-CCS during the installation of the cutoff wall would be managed through the use of rigorous safety protocols, personal protective equipment, and appropriate disposal practices. Hydrogeological changes would be expected under the Source Control-CCS alternative, such as altering flow patterns in the UA, redirecting groundwater flow around the cutoff wall, and causing changes to normal hydraulic gradients. However, changes to groundwater flow would not be expected to have an effect on the potential for the exposure of humans and environmental receptors to any wastes.
Long-Term Reliability of the Engineering and Institutional Controls (Section 2.2.8; IAC Section 845.670(e)(1)(G))	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, long-term reliability of source control would be same for both corrective action alternatives. Residual plume management under the Source Control-GWP alternative would be reliable because it would rely on physical and geochemical attenuation processes and active monitoring. If necessary, remedy optimizations would be implemented under the adaptive site management program.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, long-term reliability of source control would be same for both corrective action alternatives. Cutoff walls are a proven remedy and have been implemented at many sites. Thus, residual plume management under the Source Control-CCS alternative would be reliable, provided it is constructed in accordance with standard design specifications. The remedy consists of a passive, below-grade structure, which would not require any O&M activities once it is installed. The construction of the cutoff wall would require temporarily removing a portion of the previously installed WAPS final cover. This procedure may allow additional stormwater to infiltrate the CCR, potentially leading to a temporary reversal of some positive effects that have occurred since the completion of the final cover system in 2020. A CCR-contact stormwater management

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
		system would be required to manage and discharge the contact stormwater *via* an NPDES permitted outfall. Quality control (QC) and quality assurance (QA) programs will be required during and after the construction to ensure the effectiveness of the cutoff wall. If necessary, remedy optimizations would be implemented under the adaptive site management program.
Potential Need for Replacement of the Remedy (Section 2.2.9; IAC Section 845.670(e)(1)(H))	Replacement of the residual plume management remedy under the Source Control-GWP alternative would likely be unnecessary, because it would not require the installation, operation, and maintenance of engineered systems or structures. Adaptive site management strategies would be used to implement remedy optimizations, if necessary, to ensure that remedial goals are achieved.	Replacement of the residual plume management remedy under the Source Control-CCS alternative would likely be unnecessary, because the cutoff wall is a robust, engineered, and maintenance-free subsurface structure. The final cover system portion of this alternative would need ongoing maintenance per the IEPA approved Post-Closure Care Plan, but it is a passive and engineered structure that is unlikely to need replacement. Adaptive site management strategies would be used to implement remedy optimizations, if necessary, to ensure that remedial goals are achieved.
Degree of Difficulty Associated with Constructing the Remedy (Section 2.3.1; IAC Section 845.670 (e)(3)(A))	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there would be no further construction difficulties associated with the implementation of source control. Residual plume management under the Source Control-GWP alternative would rely on physical and geochemical attenuation processes and therefore would not pose any significant construction challenges.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there would be no further construction difficulties associated with the implementation of Source Control. Residual plume management under the Source Control-CCS alternative would rely on a continuous containment system to enclose the CCR within the WAPS, and physical and geochemical attenuation processes to address downgradient groundwater quality impacts. Some challenges may be encountered during the construction of the cutoff wall, including the following: 1. Specialized equipment, including large cranes, clamshells, slurry cutters, batch plants, and grading

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
		equipment may be needed to construct the cutoff wall. 2. Construction challenges, such as encountering highly permeable layers leading to slurry loss, facing obstructions that necessitate specialized techniques and/or equipment for progression, or experiencing sidewall instability, may arise. These challenges could be managed during cutoff wall construction. 3. Additional engineering assessments and monitoring programs would be necessary to monitor the embankment for indications of distress, such as deformation or cracking, throughout the cutoff wall construction process, because the cutoff wall would be installed through an existing impoundment embankment. 4. The construction of the cutoff wall would require temporarily removing a portion of the previously installed WAPS final cover in areas where conflict with the cutoff wall. This procedure may allow additional stormwater to infiltrate the CCR, potentially leading to a temporary reversal of some positive effects that have occurred since the completion of the final cover system in 2020. A CCR-contact stormwater management system would be required to manage and discharge the contact stormwater *via* an NPDES permitted outfall. 5. Ongoing QC is essential during construction, as part of QA activities, to prevent defective features. Additionally, post-construction QA programs, such as coring and testing, may be necessary to validate the quality of the constructed barrier.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
		6. Ongoing monitoring and QA/QC testing for slurry mixing, placement, or soil-bentonite mixing are critical to ensure the performance of the cutoff wall.
Expected Operational Reliability of the Remedy (Section 2.3.2; IAC Section 845.670 (e)(3)(B))	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. The operational reliability of the source control would be the same for both corrective action alternatives. Residual plume management under the Source Control-GWP alternative would have high operational reliability because this alternative would rely on natural processes and active monitoring. However, it should be noted that some arsenic re-mobilization may occur as groundwater returns to background conditions, which may cause an impact to the time to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025). Adaptive site management strategies would be used to implement remedy optimizations, if necessary.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. The operational reliability of the source control would be the same for both corrective action alternatives. Residual plume management under the Source Control-CCS alternative would have high operational reliability because it is an established technology, as long as the cutoff wall is constructed in accordance with standard design specifications. This CCS would provide full isolation of all CCR from the surrounding environment as a result of the cutoff wall extending into bedrock and from the existing cover. However, this alternative would require the temporary removal of a portion of the completed cover over the WAPS, which could potentially cause additional stormwater to percolate into the CCR and result in a temporary reversal of certain positive effects that have occurred since the completion of source control in 2020. These temporary impacts would diminish once the final cover system is repaired. Adaptive site management strategies would be used to implement remedy optimizations, if necessary.
Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies (Section 2.3.3; IAC Section 845.670 (e)(3)(C))	Specific permits and approvals associated with source control were the same for both corrective action alternatives and were discussed in the Closure Plan (Geosyntec Consultants, Inc., 2017). Residual plume management under the Source Control-GWP alternative would	Specific permits and approvals associated with source control were the same for both corrective action alternatives and were discussed in the Closure Plan (Geosyntec Consultants, Inc., 2017). The Source Control-CCS alternative would require approvals and permits,

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	not need additional permits from other agencies, other than the approval of the Corrective Action Plan.	including construction stormwater controls and BMPs, a joint water pollution control construction and operating permit. An IDNR Dam Safety modification permit would be required for modifications of the WAPS embankment. A modification to the existing NPDES permit would be necessary to discharge the CCR-contact stormwater generated during the construction phase.
Availability of Necessary Equipment and Specialists (Section 2.3.4; IAC Section 845.670 (e)(3)(D))	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further equipment and specialist needs associated with the implementation of the source control remedy. Residual plume management under the Source Control-GWP alternative would require standard environmental monitoring equipment and groundwater professionals. Specialists such as geologists, hydrogeologists, statisticians (*i.e.*, statistical analysis), and geochemists would be available to collect and evaluate the data.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further equipment and specialist needs associated with the implementation of the source control remedy. Residual plume management under the Source Control-CCS alternative would require standard environmental monitoring equipment similar to those under the Source Control-GWP alternative. In addition, building the cutoff wall requires the expertise of a specialized contractor with a background in constructing similar types of walls in comparable geologic environments. Specialized equipment, including large cranes, clamshell buckets, slurry cutters, batch plants, or other equipment would be required to construct the cutoff wall. Specialists, such as design engineers, construction managers, and contractor staff, involved in the design and construction of cutoff walls would be essential during both phases. Monitoring the WAPS embankments during cutoff wall construction would require expertise in geotechnical instrumentation, including the use of inclinometers, survey prisms, vibrating wire piezometers, and visual inspection for signs of distress. Equipment and experts with geosynthetics design and installation, specifically with seaming new geosynthetics to an existing final cover

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
		system, would be required for the final cover system restoration. There may be backlogs associated with the equipment and specialists discussed above, due to the high existing demand for specialty ground improvement contractors and design specialists who are engaged with similar projects in sectors like electric utilities, dams/levees, solid waste management, and other areas.
Available Capacity and Location of Needed Treatment, Storage, and Disposal Services/Comply with Standards for Management of Wastes as Specified in Section 845.680(d) (Section 2.3.5; IAC Section 845.670 (e)(3)(E)/ IAC section 845.670(d)(5))	No treatment, storage, or disposal services would be required for residual plume management under Source Control-GWP alternative, as GWP would not generate any significant volume of waste or wastewater.	Residual plume management for the Source Control-CCS alternative would generate waste during the cutoff wall construction phase; waste would include geosynthetics and other debris from removing the final cover system, cutoff wall spoils, and contact stormwater. 1. Geosynthetics and other debris would be disposed of in an off-Site landfill that has sufficient volume. 2. CCR-containing cutoff wall spoils would be temporarily staged on-Site and then disposed off-Site or beneficially used on-Site as compacted contouring fill. 3. Non CCR-impacted spoils would be disposed of at an appropriate on-Site location. 4. CCR-contact stormwater generated during construction would be pumped to the on-Site treatment pond and then discharged *via* an NPDES permitted outfall. No wastes would be expected to be generated during operation of the cutoff wall; consequently, no additional treatment, storage, or disposal services would be necessary for this remedy.
The Degree to Which Community Concerns Are Addressed by the Remedy (Section 2.4; IAC Section 845.670(e)(4))	Some communities have expressed concerns over groundwater quality at CCR surface impoundments. The combination of source control (*i.e.*, CIP using a consolidate-and-cap approach)	Some communities have expressed concerns over groundwater quality at CCR surface impoundments. The combination of source control (*i.e.*, CIP using a consolidate-and-cap approach)

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	and residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Geosyntec Consultants, Inc., 2017; Appendix B Ramboll, 2025b), thus addressing these concerns. A public meeting was held on April 8, 2025, pursuant to requirements under IAC Section 845.710(e). Questions raised by attendees were addressed at the meeting;, a written summary of the questions and responses were prepared.	and residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Geosyntec Consultants, Inc., 2017; Appendix B; Ramboll, 2025b), thus addressing these concerns. A public meeting was held on April 8, 2025, pursuant to requirements under IAC Section 845.710(e). Questions raised by attendees were addressed at the meeting; a written summary of the questions and responses were prepared.
Remove from the Environment as Much of the Contaminated Material That Was Released from the CCR Surface Impoundment as Is Feasible, Taking into Account Factors Such as Avoiding Inappropriate Disturbance of Sensitive Ecosystems (Section 2.5; IAC Section 845.670(d)(4))	There have been no known releases of CCR at the WAPS. Both potential corrective action alternatives include source control and residual plume management efforts. The source control included the a consolidate-and-cap approach to control, minimize or eliminate, post-closure infiltration of liquids into the impounded CCR. Therefore, this approach is preventing the release of contaminated material from the WAPS to the extent that is feasible. Additionally, residual plume management under the Source Control-GWP alternative would address impacted groundwater by relying on natural physical and geochemical attenuation processes to reduce the residual concentrations of CCR-related constituents in groundwater. Site-specific evaluations have shown that groundwater polishing would reduce the groundwater concentrations and mobility of inorganic contaminants (including boron and sulfate), through physical and geochemical attenuation mechanisms, especially after the implementation of source control (Appendix E; Geosyntec Consultants, Inc., 2025). However, it should be noted some arsenic re-mobilization may	There have been no known releases of CCR at the WAPS. Both potential corrective action alternatives include source control and residual plume management efforts. The source control included the a consolidate-and-cap approach to control, minimize or eliminate, post-closure infiltration of liquids into the impounded CCR. Therefore, this approach is preventing the release of contaminated material from the WAPS to the extent that is feasible. Additionally, residual plume management under the Source Control-CCS alternative would employ a cutoff wall which would be incorporated into the final WAPS cover system to create a continuous low-permeability barrier that fully contains the CCR within the WAPS. This system ensures isolation from the surrounding environment through lateral containment by the deep cutoff wall, surface containment by the existing geomembrane cover, and a natural barrier provided by the competent shale bedrock below. The temporary removal of the final cover system implemented during closure in 2020 would also occur during construction, which would generate

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-CCS
	occur as groundwater returns to background conditions at the WAPS, which may cause an impact to the time required to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025). No ecosystems would be disturbed because no construction activities are expected under the Source Control-GWP alternative.	CCR-contact stormwater that would be managed appropriately. The construction activities may cause some negative impacts on natural resources and habitat located atop the WAPS final cover system and near the Site. However, the total duration of the construction is expected to be 18 to 24 months, so any construction-related impacts to ecosystems would be limited to the short term. Source Control-CCS would be more effective at controlling releases than Source Control-GWP. CCS would isolate CCR from the surrounding environment on all sides and in particular would prevent releases of CCR-related constituents associated with the high groundwater transmissivity of the sand and gravel deposits in the UA.

Notes:
BCU = Bedrock Confining Unit; CCR = Coal Combustion Residual; CCS = Continuous Containment System; CIP = Closure-in-Place; GWP = Groundwater Polishing; GWPS = Groundwater Protection Standard; IAC = Illinois Administrative Code; IDNR = Illinois Department of Natural Resources; NPDES = National Pollutant Discharge Elimination System; O&M = Operations and Maintenance; Source Control-CCS = Source Control with a Continuous Containment System; Source Control-GWP = Source Control with Groundwater Polishing; UA = Uppermost Aquifer; WAPS = Western Ash Pond System.

1 Introduction

1.1 Site Description and History

1.1.1 Site Location and History

Dynegy Midwest Generation, LLC's (DMG) Hennepin Power Plant is an electric power generating facility with coal-fired units located approximately 4 miles northeast of the Village of Hennepin, Illinois, along the Illinois River. The facility began operating in the early 1950s and was retired in 2019 (Ramboll, 2021). The plant had two coal-fired units constructed in 1953 and 1959 with a capacity of 70 megawatt (MW) and 210 MW, respectively (Ramboll, 2021).

1.1.2 CCR Impoundment

The Hennepin Power Plant produced and stored coal combustion residuals (CCRs) as a part of its historical operations. The West Ash Pond System (WAPS; which includes Illinois Environmental Protection Agency [IEPA] identification [ID] number [No.] W1550100002-01 and No. W1550100002-03, Vistra CCR Unit ID 804, and a National Inventory of Dams [NID] No. IL50698; Appendix B) is the subject of this report.

The WAPS was operated from 1952 through 1996. The impoundment is composed of two inactive sub-units, the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP) (Figure 1.1). Both sub-units were originally constructed as a single unit with a single perimeter dike and subsequently divided as part of operational procedures. The OWAP was approximately 27.7 acres in size and accepted mainly bottom ash, slag, as well as mixed coal ash. The 4.7-acre OWPP was used as a secondary pond and is located at the western end of the impoundment. Effluent from the impoundment was discharged to surface water until 1989 when the Ponds No. 1 and No. 3 were consolidated as OWAP and divided into primary and secondary cells within the OWAP. This report refers to the three sub-units as a single CCR unit, *i.e.*, WAPS (OBG, Part of Ramboll, 2019).

A Closure and Post-Closure Plan for the WAPS was developed in accordance with Title 40 Part 257 and was approved by IEPA in 2018. Source control using a consolidate-and-cap approach was completed in 2020 (Appendix C; Ramboll, 2024a), which is discussed in Section 2.1.

Figure 1.1 Site Location Map. Adapted from Ramboll (2025c).

1.1.3 Surface Water Hydrology

The WAPS is located within the DePue Lake-Ohio River Watershed (12-digit Hydrologic Unit Code: 071300010804), which is located in the greater Lower Illinois-Senachwine Lake (8-digit Hydrologic Unit Code: 07130001) (USGS, 2024). The Illinois River is located less than 200 ft north of the WAPS and flows from east to west (Geosyntec Consultants, Inc., 2017). As described below (Section 1.1.4, Hydrogeology), the Illinois River acts as a regional sink for surface water and groundwater in the vicinity of the Site.

The Illinois River is the largest surface water body in the area. The IEPA classifies the river as a General Use Water: it is designated for aquatic life and use in primary contact recreation; however, it is not designated for use in food processing or as a public water supply. The segment of the Illinois River adjacent to the Site (Section D-16) is listed on the 2022 Illinois Section 303(d) List as being impaired for fish consumption, due to mercury and polychlorinated biphenyls (PCBs). DePue Lake, which is located north of the Site along the north bank of the Illinois River, is listed as impaired for aquatic life due to cadmium, endrin, silver and zinc; it is also listed as impaired for fish consumption due to mercury and polychlorinated biphenyls (IEPA, 2022, 2019).

The former National Pollutant Discharge Elimination System (NPDES) permit (IL001554) outfall 005, which was a discharge culvert at the OWPP, was removed during closure of the WAPS in 2020 (IEPA, 2011; Geosyntec Consultants, Inc., 2017). During closure, residual liquids pumped from the WAPS was eventually discharged through Outfall 003, which is located approximately one mile east of the WAPS, under the same permit (Geosyntec Consultants, Inc., 2017).

1.1.4 Hydrogeology

The geology underlying the Site in the vicinity of the WAPS consists of three distinct hydrostratigraphic units (Appendix C; Ramboll, 2024a; Geosyntec Consultants, Inc., 2017):

- **Uppermost Aquifer (UA):** The UA composed of mixed alluvial deposits (classified as Cahokia alluvium consisting of clay, silt, and sand), which overlie coarser grained outwash sand and gravel deposits (classified as Henry Formation). This unit is highly permeable and is the uppermost aquifer and primary groundwater transport pathway in the vicinity of the West Ash Pond System.
- **Bedrock Confining Unit (BCU):** The BCU is defined by Pennsylvanian age shale with minor layers of limestone, sandstone, and coal. This low permeability unit defines the lower boundary of the Uppermost Aquifer Unit at WAPS.

The groundwater movement in the unconsolidated materials is consistent with surface topography and flows north and west near the Site towards the Illinois River, which serves as a large regional hydraulic boundary. Precipitation infiltration recharges groundwater. Groundwater typically flows horizontally within the three hydrostratigraphic units at the Site, with converging upward flow near and beneath the river. Prior to the closure during the impoundment operations, substantial local recharge to groundwater from sluicing of ash created radial flow conditions near the impoundment. Groundwater flow direction is primarily northwest towards the river during post-closure conditions (Appendix C; Ramboll, 2024a; Appendix D; Ramboll, 2024b).

During groundwater's interaction with surface water, CCR-related constituents may partition between sediments and the surface water column. It should be noted that many CCR-related constituents can also arise from other industrial sources and occur naturally in sediments and surface water. As a result, their presence in the sediments and/or surface water of the Illinois River does not necessarily signify contributions from the WAPS.

1.1.5 Site Vicinity

The WAPS is surrounded by the Illinois River to the north, industrial properties to the east (Tri-Con Materials) and south (Tri-Con Materials and Washington Mills), agricultural land to the southwest, and the Hennepin Power Station to the west. Tri-Con Materials produces various fill and washed sand, gravel, rock and boulder products (Ramboll, 2018-2020). Washington Mills produces abrasive grains and specialty electro-fused minerals (Ramboll, 2018-2020).

Notable natural areas and recreational areas in the vicinity of the WAPS include the Illinois River and the Donnelley/DePue State Fish and Wildlife Areas complex, which is located opposite the WAPS along the northern bank of the Illinois River. The Illinois River is popular for canoeing and other forms of water recreation (IDNR, 2021). The nearby DePue Lake and Lyons Lake are popular areas for recreational boating and fishing (Illinois River Road National Scenic Byway, 2021; HookandBullet.com, 2021).

1.2 Part 845 Regulatory Review and Requirements

Title 35, Part 845 of the Illinois Administrative Code (IAC) (IEPA, 2021) requires that a Corrective Action Alternatives Analysis (CAAA) be performed as part of the remedy selection, prior to undertaking any corrective actions at certain CCR-containing impoundments where exceedances of GWPSs have been identified. Because exceedances[2] of GWPSs in groundwater associated with the WAPS have been identified for arsenic, boron, lithium, sulfate, and total dissolved solids (TDS) (Appendix D; Ramboll, 2024b), this report presents a CAAA for the WAPS pursuant to the requirements under IAC Section 845.670. The goal of a CAAA is to holistically evaluate a range of factors for the various corrective actions being considered at an impoundment, including the efficiency, reliability, and ease of implementation of the corrective action; its potential positive and negative short- and long-term impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021). A CAAA is a decision-making tool that is designed to aid in the selection of a corrective action alternative.

[2] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or Groundwater Protection Standards (GWPS) as described in the proposed groundwater monitoring program, which was submitted to IEPA on October 25, 2021 as part of Dynegy Midwest Generation's operating permit application for the WAPS (Burns & McDonnell, 2021). The operating permit application, including the proposed groundwater monitoring program, remains under review by IEPA and therefore Dynegy Midwest Generation has not identified any actual exceedances.

2 Corrective Action Alternatives Analysis

This section presents the CAAA pursuant to requirements under IAC Section 845.670 (IEPA, 2021). The goal of a CAAA is to fully evaluate proposed viable corrective measures that were identified in the CMA. The CAAA evaluates potential corrective actions with respect to a wide range of factors, including the performance, reliability, and ease of implementation of the corrective action; its potential impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021).

Per IAC Section 845.670(d) (IEPA, 2021), any corrective actions selected under a Corrective Action Plan must:

1. Be protective of human health and the environment;
2. Attain the groundwater protection standards specified in Section 845.600;
3. Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in Section 845.600 into the environment;
4. Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, considering factors such as avoiding inappropriate disturbance of sensitive ecosystems; and
5. Comply with standards for management of wastes as specified in Section 845.680(d).

At the WAPS, a CAAA is required because groundwater monitoring associated with the WAPS identified exceedances of the GWPSs. Groundwater monitoring was conducted in accordance with the proposed groundwater monitoring plan (GMP) between 2015 and 2023 (Appendix D; Ramboll, 2024b). The groundwater samples collected from groundwater compliance monitoring wells were used to evaluate compliance with the groundwater quality standards listed in IAC Section 845.600(a). As of the date of this report, arsenic, boron, lithium, sulfate, and total dissolved solids (TDS) were identified as constituents/parameters with exceedances of their corresponding GWPSs (Appendix D; Ramboll, 2024b).

Two potential corrective actions are evaluated in this CAAA: Source Control with Groundwater Polishing (Source Control-GWP), and Source Control with a Continuous Containment System (Source Control-CCS). Both alternatives were identified as viable approaches in the CMA (Appendix C; Ramboll, 2024a). Each of these corrective action alternatives is described below in Section 2.1.

It should be noted that Source Control-GWP, Source Control with a Cutoff Wall, and Source Control with *In-Situ* Stabilization (ISS) were identified in the CMA as viable remedial approaches (Appendix C; Ramboll, 2024a). However, during subsequent evaluations, the remedial approaches were modified. Remedy modifications include the following:

- Source control-ISS was determined infeasible and excluded for further evaluation due to significant potential risks, including the need to temporarily remove half of the previously installed WAPS final cover. Removal of the final cover system would result in significant stormwater infiltration and potentially lead to reducing the effectiveness of the completed source control. In addition, ISS would involve managing tens of thousands of cubic yards of CCR and CCR-impacted cuttings on

the WAPS surface, increasing the risk of releasing CCR-contaminated stormwater and sediments during construction, which could negatively impact nearby sensitive areas.

- Source Control-Cutoff Wall was expanded into the Source Control-CCS alternative, which is evaluated in this report. The continuous containment system (CCS) integrates the cutoff wall with the existing final cover to provide full lateral and surface isolation of CCR from the surrounding environment. The wall would be keyed into competent shale bedrock to provide base subsurface containment below the WAPS.

2.1 Corrective Action Alternative Descriptions

For both corrective actions evaluated in this CAAA, source control is the primary remedy. US EPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (US EPA, 2015b). The source control for the WAPS consisted of closure-in-place (CIP) using a consolidate-and-cap approach (Geosyntec Consultants, Inc., 2017). Specific elements of this approach competed in 2020 included:

- Removal of residual liquids (unwatering) within the OWAP and OWPP *via* a pumping system and discharge through existing NPDES Outfall 003.
- Installation of a sheet pile wall and a compacted clay buttress at the splitter dike between the OWAP and OWPP for dike support and seepage control during excavation of the OWPP. The sheet pile and buttress remain in place after closure to physically separate CCR that were capped in the OWAP from the excavated area in the OWPP.
- Excavation of CCR and dike soils from the OWPP and placement of the excavated CCR in the OWAP as structural fill. The excavated area in OWPP resulted in a 6-acre depression, which was seeded to foster native vegetation growth and currently functions as an ephemeral pond for wildlife habitat.
- Placement of a geosynthetic cover system over the OWAP, which consisted of a 40-mil linear low-density polyethylene (LLDPE) geomembrane liner, 1.5 ft of soil cover and 0.5 ft vegetative layer.
- Removal of existing NPDES Outfall 005 and the associated discharge culvert at the OWPP.
- Establishing and maintaining native vegetative growth on the OWAP final cover, to minimize erosion.
- Establishing a gravel roadway along the south and west of the OWPP to allow for vehicular access to the adjacent Donnelly Wildlife Management Area.
- Installation of a stormwater management system.

These above source control activities included excavation of CCR from the OWPP and consolidation into OWAP, and the installation of a low-permeability final cover system. These activities were designed to control, minimize or eliminate, post closure infiltration of liquids into the impounded CCR. Closure activities specifically included removal of impounded water and excavation of CCR and one foot of soil below the CCR from OWPP to consolidate into OWAP, and installation of a final cover system consisting of a geosynthetic layer, a protective soil layer and establishment of a vegetative cover. These measures (installation of a geosynthetic cap and consolidation of CCR) control to the maximum extent feasible the migration of CCR constituents to groundwater, thus facilitating the achievement of the GWPSs in accordance with IAC Section 845.600. As demonstrated by the groundwater modeling in support of the Closure Plan, source control would result in a drop of hydraulic pressure beneath the final cover system, a

significant reduction in groundwater concentrations, and over time would result in a reduction in the extent of groundwater impacts to within the footprint of the impoundment (Geosyntec Consultants, Inc., 2017). Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS would also be controlled and minimized.

In addition to source control, the corrective actions evaluated in this CAAA include residual plume management. Two potential corrective actions, identified as viable in the CMA and after further assessment, are evaluated in this CAAA for the WAPS (Appendix B; Ramboll, 2025a):

- **Alternative 1:** Source Control with Groundwater Polishing (Source Control-GWP);
- **Alternative 2:** Source Control with a Continuous Containment System (Source Control-CCS).

For both corrective action alternatives, adaptive site management strategies would be integrated into residual plume management. This approach ensures the timely incorporation of new Site information throughout the corrective action process in order to optimize the remediation and expedite achievement of the GWPSs. As part of the adaptive site management approach, system performance and residual plume conditions would be monitored throughout the implementation of the selected corrective action. If groundwater concentrations do not respond as expected to the corrective action, the adaptive site management approach would enable prompt adjustments, optimizations, or replacement of the remedy to ensure overall effectiveness.

2.1.1 Alternative 1: Source Control-GWP

The first corrective action alternative is Source Control-GWP. This remedy includes source control (*i.e.*, CIP using a consolidate-and-cap approach) combined with residual plume management based on physical and geochemical processes that would reduce groundwater concentrations downgradient of the WAPS. Groundwater polishing mechanisms were evaluated using geochemical speciation and reaction models. The primary objective of the geochemical model was to support the evaluation of groundwater polishing as a potential remedy for the Site. The model focused on evaluating the dominant geochemical reactions that may occur at time scales relevant to groundwater flow, including adsorption and mineral dissolution/precipitation reactions (*i.e.*, iron and aluminum hydroxides, carbonates, and some sulfates) (Appendix E; Geosyntec Consultants, Inc., 2025). Model inputs included geochemically reactive solid mineral phases, downgradient groundwater composition, and background groundwater composition derived from Site-specific data. Speciation models analyzed the distribution of chemical constituents between solid and aqueous phases, while reaction models assessed how these distributions may shift in response to changing Site conditions (US EPA, 2015).

Components of residual plume management for the Source Control-GWP alternative include:

- Groundwater concentrations would be reduced in the downgradient plume as a result of physical and geochemical attenuation processes. Site-specific evaluations have shown that groundwater polishing would reduce the groundwater concentrations and mobility of inorganic contaminants (including boron, lithium, and sulfate), through natural physical and geochemical attenuation mechanisms, especially after the implementation of source control (Appendix E; Geosyntec Consultants, Inc., 2025). Specifically, chemical attenuation of contaminants is feasible *via* sorption to aquifer solids, particularly iron and aluminum oxides under current conditions. Attenuation *via* sorption onto mineral surfaces should remain stable for boron and sulfate under post-closure

conditions. However, it should be noted some arsenic[3] re-mobilization may occur as groundwater returns to background conditions at the WAPS, which may cause an impact to the time to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025).

- Corrective action groundwater monitoring using a corrective action groundwater monitoring network designed in accordance with IAC Section 845.680(c), which would be installed within the plume that lies beyond the waste facility boundary.
- Adaptive site management strategies for this alternative would include geochemical modeling. Groundwater monitoring results would be evaluated and compared to the model-predicted concentrations. In situations in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques to achieve the GWPSs would be evaluated, and if viable, incorporated as per IAC Section 845.680(b).
- Corrective action confirmation groundwater sampling would be performed for 3 years after GWPSs have been achieved.
- Following the completion of the corrective action confirmation monitoring period, a report and certification for Corrective Action Completion would be prepared and submitted to IEPA as per IAC Section 845.680(e).

The overall corrective action implementation duration for this alternative is approximately 33 years (390 months) after approval of the corrective action plan (Appendix B; Ramboll, 2025a), including:

- Approximately 29 years (348 months) of corrective action monitoring (*i.e.*, time to meet GWPSs),
- At least 3 years (36 months) of corrective action confirmation monitoring,[4] and
- Approximately 6 months associated with post-closure reporting (Appendix B; Ramboll, 2025a).

2.1.2 Alternative 2: Source Control-CCS

The second corrective action alternative is Source Control-CCS. This remedy includes source control and uses a continuous containment system (*i.e.*, a deep groundwater cutoff wall tied into the existing the final cover system) as the residual plume management approach. The cutoff wall would extend from the top of the WAPS perimeter dikes completely through the UA and penetrate into the underlying competent shale bedrock. The total length of the cutoff wall is expected to be approximately 5,200 ft, enclosing the CIP portions of the WAPS. The wall would be constructed from ground surface to a depth of 90 ft below ground surface (bgs)[5] (Appendix B; Ramboll, 2025a). The cutoff wall would be constructed using either a mixture of soil and bentonite or cement and bentonite, with a thickness ranging from 2 to 3 ft, and would have a hydraulic conductivity of approximately 1.0×10^{-7} centimeters per second (cm/s). The existing final cover system would be extended and integrated with the cutoff wall, creating a continuous low-permeability physical barrier. This would fully contain the CCR within the WAPS, isolating it from the surrounding environment on all sides through:

- A deep cutoff wall ensuring lateral containment on all sides of the CCR;

[3] It should be noted that not all arsenic in groundwater is associated with the WAPS. Some of the arsenic is likely naturally occurring and/or associated with other sources.
[4] It should be noted that post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section. 845.780(c).
[5] This depth corresponds to an approximate elevation of 375 ft. All elevations in this report are in the North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

- The existing low-permeability geomembrane final cover system providing surface containment over the CCR;
- Competent shale bedrock acting as a low-permeability barrier beneath the CCR.

The continuous containment system is a long-term, low-maintenance physical barrier between the WAPS and the surrounding environment. As indicated by groundwater modeling, the continuous containment system is unlikely to cause liquid buildup within the contained CCR mass, and thus supplemental groundwater extraction or active gradient control within the WAPS would be unnecessary. As a result, the system would control the source of releases of constituents to the environment.

Implementation of the Source Control-CCS is expected to include various tasks distributed across three major phases: pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action operations and maintenance (O&M), groundwater monitoring, and closeout (Phase 3). The activities associated with the Source Control-CCS alternative are summarized below.

- **Phase 1:** Pre-construction activities including obtaining permits from agencies and completing Site investigations and engineering designs.
- **Phase 2:** Construction of the cutoff wall. Details pertaining to the construction activities are outlined below:
  - Mobilization of equipment and materials to the Site, and preparation for Site construction;
  - The final cover system previously installed would be temporarily removed in the areas where conflicts with the cutoff wall alignment; existing Site infrastructure (*i.e.*, access roads, piezometers, monitoring wells, stormwater structures, pressure relief vents) may also be removed.
  - Construction of a 60 ft wide working pad and temporary access road to allow construction equipment access and traffic;
  - Low-permeability backfill for the cutoff wall would be generated using an on-Site batch plant. A geotechnical monitoring system would be implemented during construction to monitor the WAPS perimeter dikes. The cutoff wall would be constructed using appropriate equipment, such as crane-mounted conventional constructional equipment. Other innovative methods would be utilized if determined to be appropriate during later phase.
  - Once the construction is completed, CCR-impacted spoils and/or work pad materials would be either disposed off-Site or beneficial used within the Hennepin East Ash Pond as compacted fill beneath the final cover system. Non-CCR impacted spoils would be disposed of at an appropriate on-Site location.
  - Appropriate stormwater management system would be constructed to discharge to an NPDES permitted outfall for any contact stormwater.
  - Site restoration would occur, which include replacement of Site infrastructure that are damaged or removed during construction, as well as the repair of the final cover system.
- **Phase 3:** Corrective action operations, maintenance (O&M), and closeout. Details pertaining to each of these activities are outlined below.
  - Corrective Action O&M: Because the deep cutoff wall is a passive, below-grade structure, no O&M would be needed following its installation. Maintenance of the final WAPS cover system (as part of the CCS) would proceed in accordance with current post-closure care O&M practices.

- Adaptive site management strategies would be employed to track remediation progress and incorporate new Site information to assure the achievement of the GWPSs.
- Corrective action monitoring would be performed using a corrective action groundwater monitoring network designed in accordance with IAC Section 845.680(c), which would be installed within the plume contamination that lies beyond the waste boundary.
- Corrective action confirmation monitoring would be performed for 3 years after GWPSs have been achieved.
- Following the completion of the corrective action confirmation monitoring period, a report and certification for Corrective Action Completion would be prepared and submitted to IEPA as per IAC Section 845.680(e).

The overall corrective action implementation duration is approximately 42 to 44 years (498 to 522 months) after approval of the corrective action plan (Appendix B), including:

- Approximately 4 to 5 years (42 to 60 months) of pre-construction activities (Phase 1),
- Approximately 18 to 24 months of corrective action construction (Phase 2), and
- Approximately 37 years (438 months) of O&M and closeout (Phase 3);
    - It includes 33 years (396 months) of corrective action monitoring (*i.e.*, time to meet GWPSs), at least 3 years (36 months) of corrective action confirmation monitoring,[6] and 6 months associated with post-closure reporting.

[6] It should be noted that post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section 845.780(c).

Key parameters for the Source Control-Cutoff Wall corrective action alternative are shown in Table 2.1, below.

Table 2.1 Key Parameters for the Source Control-CCS Corrective Action Alternative[a]

Parameter[b]	Value[c]
Labor Hours	
Total On-Site Labor	29,400 hours
Total Off-Site Labor	0 hours
40% Contingency	11,800 hours
Total Labor Hours:	41,100 hours
Vehicle and Equipment Travel Miles	
Vehicles On-Site	95,600 miles
On-Site Haul Trucks (Unloaded + Loaded)	3,350 miles
Labor Mobilization	446,000 miles
Equipment Mobilization (Unloaded + Loaded)	54,100 miles
Off-Site Haul Trucks (Unloaded + Loaded)	121,000 miles
Material Deliveries (Unloaded + Loaded)	210,000 miles
Total On-Site Vehicle and Equipment Travel Miles:	99,000 miles
Total Off-Site Vehicle and Equipment Travel Miles:	831,000 miles
Total Vehicle and Equipment Travel Miles:	930,000 miles

Notes:
Source Control-CCS = Source Control with Continuous Containment System.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the source control was previously completed in 2020 and the associated labor time, equipment usage, and mileage are not discussed in this analysis.
(b) Site activities are only expected to occur during the corrective action construction phase for this alternative.
(c) Values reported in this table were rounded to reflect 3 significant figures.
Source: Appendix B, Ramboll, 2025a.

2.2 Long- and Short-Term Effectiveness and Protectiveness of Corrective Action Alternative (IAC Section 845.670(e)(1))

2.2.1 Magnitude of Reduction of Existing Risks/Be Protective of Human Health and the Environment (IAC Section 845.670(e)(1)(A)/IAC Section 845.670(d)(1))

There are no current unacceptable risks to human or ecological receptors at this Site associated with the WAPS (Appendix A; Gradient, 2025). Because current conditions do not present a risk to human health or the environment at the WAPS, there will be no unacceptable risk to human health or the environment for future conditions since the unit was already closed and source control was implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. As a result of this, the magnitude of the reduction of existing risks is the same for the two potential corrective action alternatives (IAC Section 845.670(e)(1)(A)), and both corrective action alternatives are equally protective of human health and the environment (IAC Section 84.670(d)(1)).

2.2.2 Effectiveness of the Remedy in Controlling the Source (IAC Section 845.670(e)(2)/IAC Section 845.670(d)(3))

Extent to Which Containment Practices Will Reduce Further Releases/Control the Sources of Releases to Reduce or Eliminate, to the Maximum Extent Feasible (IAC Section 845.670(e)(2)(A)/IAC Section 845.670(d)(3))

Source control was implemented for both corrective action alternatives in 2020. Source control (*i.e.*, CIP using a dewatering-and-cap approach) which included dewatering and excavation of CCR from the OWPP and consolidation into the OWAP portion of the WAPS and the installation of a low-permeability final cover system. These source control activities would limit the infiltration of precipitation into the CCR, result in a significant reduction in groundwater concentrations, and, overtime, reduce the extent of groundwater impacts to within the footprint of the impoundment based on groundwater modeling conducted in support of the Closure Plan (Geosyntec Consultants, Inc., 2017). Therefore, both corrective action alternatives would be equally and fully protective with regard to source control. The effectiveness of residual plume management for each of the corrective action alternatives with respect to source control is summarized below.

- Under the Source Control-GWP alternative, the attenuation of dissolved constituent concentrations remaining after source control would be achieved through natural physical and geochemical processes. Site-specific evaluations have shown that groundwater polishing would reduce the groundwater concentrations and mobility of inorganic contaminants (including boron and sulfate), through natural physical and geochemical attenuation mechanisms, especially after the implementation of source control (Appendix E; Geosyntec Consultants, Inc., 2025). Specifically, chemical attenuation of contaminants is feasible to some extent *via* sorption to aquifer solids, particularly iron and aluminum oxides under current conditions. Attenuation *via* sorption onto mineral surfaces should remain stable for boron and sulfate under post-closure conditions. However, it should be noted some arsenic[7] re-mobilization may occur as groundwater returns to background conditions at WAPS, which may cause an impact to the time required to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025). In cases in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques would be evaluated under the adaptive site management program, and if viable, incorporated as per IAC Section 845.680(b);
- Under the Source Control-CCS alternative, residual plume management would be achieved by the installation of the continuous containment system. Cutoff walls are a frequently used corrective measures that have been determined to be an effective approach in preventing dissolved-phase groundwater plume migration. The final WAPS cover system would be extended and integrated with the cutoff wall, creating a continuous low-permeability barrier that fully contains the CCR within the WAPS. This system ensures isolation from the surrounding environment through lateral containment by the deep cutoff wall, surface containment by the existing geomembrane cover, and a natural barrier provided by the competent shale bedrock below. Thus, this continuous barrier will isolate the CCR from the surrounding environment thus reducing and eliminating further releases. If necessary, remedy optimizations would be implemented under the adaptive site management program.

[7] It should be noted that not all arsenic in groundwater is associated with the WAPS. Some of the arsenic is likely naturally occurring and/or associated with other sources.

Although both corrective action alternatives include source control and residual plume management, Source Control-CCS would be more effective at controlling sources of releases than Source Control-GWP. Source Control-CCS would isolate CCR from the surrounding environment on all sides and in particular would prevent releases of CCR-related constituents associated with the high groundwater transmissivity of the sand and gravel deposits of the UA.

Extent to Which Treatment Technologies May Be Used (IAC Section 845.670(e)(2)(B))

Because Source Control-GWP would rely on natural attenuation processes, no additional treatment technologies would be required under this alternative. Under the Source Control-CCS alternative, contact stormwater may be generated during the construction phase, which would be pumped to the on-Site treatment pond before discharging *via* an NPDES permitted outfall. No additional treatment technologies would be required for the Source Control-CCS alternative during the operation of the CCS, because the cutoff wall is an engineered physical barrier that does not require maintenance.

2.2.3 Likelihood of Future Releases of CCR (IAC Section 845.670(e)(1)(B))

Both corrective action alternatives include source control using CIP with a consolidate-and-cap approach. A geosynthetic cover system was installed over the WAPS in 2020 in compliance with 40 CFR Part 257, Subpart D, which included a geosynthetic layer, a protective soil layer to limit infiltration, and a vegetative cover. This cover system provides increased protection against berm and surface erosion, precipitation infiltration, and other adverse effects that could potentially trigger a release of CCR. During the construction phases of the Source Control-CCS alternative, a portion of the previously installed cover system would be temporarily removed near where the cutoff wall. Any CCR-contact stormwater generated during this time would be pumped to the on-Site treatment pond before discharged *via* an NPDES permitted outfall.

There would be minimal risk of accidental CCR releases occurring post-closure under either of the corrective action alternatives.

2.2.4 Type and Degree of Long-Term Management, Including Monitoring, Operation, and Maintenance (IAC Section 845.670(e)(1)(C))

The type and degree of long-term residual groundwater plume management associated with each corrective action alternative is summarized below.

- Residual plume management for the Source Control-GWP alternative would not require the installation, operation, or maintenance of any engineered systems or structures, other than maintenance of the monitoring well network. The only long-term management activity required under this alternative would be corrective action groundwater monitoring and routine maintenance of the monitoring wells, which would continue for at least 3 years after GWPSs have been achieved for all wells, in accordance with IAC Section 845.680(c)(2). Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section 845.780(c). Based on the adaptive site management approach, remedy optimization (additional methods or techniques) may be implemented to ensure the achievement of the GWPSs.
- Residual plume management for the Source Control-CCS alternative would require construction of a deep cutoff wall. Multiple tasks would be completed over three phases: pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action operations, maintenance, and closeout (Phase 3). CCR-impacted spoils and/or work pad materials generated

during construction would be either disposed off-Site or beneficial used within the East Ash Pond as compacted fill beneath the final cover system. Non-CCR impacted spoils would be disposed of at an appropriate on-Site location (Appendix B; Ramboll, 2025a). After the installation of the cutoff wall, no O&M efforts will be required, because it is a passive, below-grade structure. However, quality assurance (QA) and quality control (QC) programs would be required as part of construction to validate the integrity of the constructed cutoff wall. Corrective action groundwater sampling and routine maintenance of the monitoring well network would continue for at least 3 years after GWPSs have been achieved for all wells, in accordance with IAC Section 845.680(c)(2). Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section 845.780(c). Based on the adaptive site management approach, remedy optimization (additional methods or techniques) may be implemented to ensure the achievement of the GWPSs.

2.2.5 Short-Term Risks to the Community or the Environment During Implementation of Remedy (IAC Section 845.670(e)(1)(D))

2.2.5.1 Safety Impacts

Best practices would be employed during construction in order to ensure worker safety and comply with all relevant regulations, permit requirements, and safety plans. However, it is impossible to completely eliminate risks to workers during construction and/or other corrective action activities. For example, injuries and fatalities can occur due to truck accidents or equipment malfunctions. Truck accidents that occur off-Site can also result in injuries or fatalities to community members. Because the source control was implemented in 2020, there is no further risk of accidents and injuries occurring during the implementation of the source control remedy. The safety impacts associated with residual plume management (*i.e.*, construction and/or O&M) for each corrective action alternative are described below.

- The Source Control-GWP alternative would not require the construction of any engineered systems or structures, and therefore no safety impacts are expected.
- The Source Control-CCS would include the construction of a deep cutoff wall to contain CCR within the WAPS. Because the cutoff wall is a passive, subsurface structure, no O&M would be needed following installation. Therefore, potential safety concerns are only associated with the construction of the cutoff wall.

Worker Risks

On-Site accidents include injuries and deaths arising from the use of heavy equipment and/or earthmoving operations during Site activities. Off-Site accidents include injuries and deaths due to vehicle accidents during labor and equipment mobilization/demobilization, as well as materials/supplies hauling and deliveries.

As discussed in Section 2.1.1, there are no construction activities or operational requirements associated with residual plume management for the Source Control-GWP alternative. Thus, no worker injuries or fatalities are expected under the Source Control-GWP alternative. Ramboll estimates that residual plume management for the Source Control-CCS corrective action alternative would require 29,400 on-Site labor hours (Appendix B; Ramboll, 2025a). The US Bureau of Labor Statistics (US DOL, 2020a,b) provides an estimate of the hourly fatality and injury rates for construction workers. Based on the accident rates reported by the US Bureau of Labor Statistics and the on-Site labor hours reported in Appendix B, we estimate that

approximately 0.30 worker injuries and 2.7×10^{-3} worker fatalities would occur on-Site under the Source Control-CCS corrective action alternative (Table 2.2).

Table 2.2 Expected Number of On-Site Worker Accidents Under Each Corrective Action Alternative[a,b]

Corrective Action Alternative	Injuries	Fatalities
Source Control-GWP	0	0
Source Control-CCS	0.30	2.7×10^{-3}

Notes:
Source Control-CCS = Source Control with Continuous Containment System; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the worker accidents associated with source control were previously estimated in the Closure and Closure Care Plan and are not repeated in this analysis.
(b) Worker accidents associated with groundwater sampling and monitoring are not included in this analysis for any of the alternatives.

The Source Control-CCS alternative would result in off-Site hauling, labor and equipment mobilization/demobilization, and material deliveries (Table 2.1). For residual plume management under the Source Control-CCS alternative, a total of approximately 831,000 off-Site vehicle and equipment travel miles would be required. In contrast, for residual plume management under the Source Control-GWP corrective action alternative, no off-Site vehicle and equipment travel miles would be required (Appendix B; Ramboll, 2025a). The United States Department of Transportation (US DOT) provides estimates of the expected number of fatalities and injuries "per vehicle mile driven" for drivers and passengers of large trucks and passenger vehicles (US DOT, 2023). Table 2.3 shows the expected number of off-Site accidents under each corrective action alternative due to all categories of off-Site vehicle usage. For these calculations, it was assumed that labor mobilization/demobilization would rely upon passenger vehicles (cars or light trucks, including pickups, vans, and sport utility vehicles) and that hauling, equipment mobilization/demobilization, and material deliveries would rely upon large trucks. Based on US DOT's accident statistics and the mileage estimates in Appendix B, an estimated 0.35 worker injuries and 0.013 worker fatalities would be expected to occur due to off-Site activities under the Source Control-CCS alternative while there are no off-Site accidents expected under the Source Control-GWP alternative.

Table 2.3 Expected Number of Off-Site Worker Accidents Related to Off-Site Car and Truck Use Under Each Corrective Action Alternative[a]

Off-Site Vehicle Use Category	Source Control-GWP		Source Control-CCS	
	Injuries	Fatalities	Injuries	Fatalities
Hauling	0	0	0.025	1.9×10^{-3}
Labor Mobilization/Demobilization	0	0	0.27	4.2×10^{-3}
Equipment Mobilization/Demobilization	0	0	0.011	8.5×10^{-4}
Material Deliveries	0	0	0.044	3.3×10^{-3}
Total:	0	0	0.35	0.013

Notes:
Source Control-CCS = Source Control with Continuous Containment System; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the source control was previously completed in 2020, and the worker accidents associated with source control are not discussed in this analysis.

Overall, considering accidents occurring both on- and off-Site, no worker injuries and worker fatalities would be expected to occur for residual plume management under the Source Control-GWP alternative;

and 0.65 worker injuries and 0.013 worker fatalities would be expected to occur for residual plume management under the Source Control-CCS alternative. Thus, overall risks to workers would be higher under the Source Control-CCS alternative and lower under Source Control-GWP alternative.

Community Risks

Vehicle accidents that occur off-Site can result in injuries or fatalities among community members as well as workers. Based on the accident statistics reported by US DOT (2023) and the off-Site travel mileages reported in Appendix B (and summarized in Table 2.1), off-Site vehicle accidents could result in an estimated 0.21 injuries and 2.5×10^{-3} fatalities among community members (*e.g.*, people involved in haul truck accidents that are neither haul truck drivers nor passengers, including pedestrians, drivers of other vehicles, *etc*.) for residual plume management under the Source Control-CCS alternative (Table 2.4). No off-Site mileage is expected under the Source Control-GWP alternative, and thus no off-Site risks are expected under the Source Control-GWP alternative. Therefore, off-Site impacts on nearby residents, including injuries or fatalities, would be higher under the Source Control-CCS alternative.

Table 2.4 Expected Number of Community Accidents Under Each Corrective Action Alternative[a]

Off-Site Vehicle Use Category	Source Control-GWP		Source Control-CCS	
	Injuries	Fatalities	Injuries	Fatalities
Hauling	0	0	0.032	2.3×10^{-4}
Labor Mobilization/Demobilization	0	0	0.11	1.7×10^{-3}
Equipment Mobilization/Demobilization	0	0	0.014	1.1×10^{-4}
Material Deliveries	0	0	0.055	4.1×10^{-4}
Total:	0	0	0.21	2.5×10^{-3}

Notes:
Source Control-CCS= Source Control with Continuous Containment System; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the source control was previously completed in 2020, and the worker accidents associated with source control are not discussed in this analysis.

2.2.5.2 Cross-Media Impacts to Air

Air pollution can occur both on-Site (*e.g*., construction activities) and off-Site (*e.g*., along transportation routes), potentially impacting workers as well as community members. Diesel emissions are a major source of air pollutants and greenhouse gas (GHG) emissions at construction sites. Diesel exhaust contains air pollutants, including nitrogen oxides (NO_x), particulate matter (PM), carbon monoxide (CO), and volatile organic compounds (VOCs) (Hesterberg *et al*., 2009; Mauderly and Garshick, 2009). Construction equipment also emits GHGs, including carbon dioxide (CO_2) and possibly nitrous oxide (N_2O). The potential impact of each corrective action alternative on GHG emissions is proportional to the use of construction vehicles and equipment that are required for residual plume management.

Source control (*i.e*., CIP using a consolidate-and-cap approach) was implemented for both potential corrective action alternatives, and there are no further air impacts associated with source control. On-Site emissions would be higher for residual plume management under the Source Control-CCS alternative, due to the greater amount of on-Site vehicle travel miles required under this corrective action alternative (99,000 total on-Site travel miles under the Source Control-CCS alternative while no on-Site travel miles under the Source Control-GWP; Section 2.1.1 and Tables 2.1). Off-Site emissions would similarly be higher for residual plume management under the Source Control-CCS alternative due to the greater amount of off-Site vehicle and equipment travel miles required under this alternative (831,000 total off-Site travel miles

under the Source Control-CCS alternative while no off-Site travel miles under the Source Control-GWP alternative). In summary, air impacts would be higher for the Source Control-CCS alternative than the Source Control-GWP alternative.

2.2.5.3 Cross-Media Impacts to Surface Water and Sediments

Under both corrective action alternatives, the source control was implemented in 2020 (*i.e.*, CIP using a consolidate-and-cap approach), and constituent mass flux from groundwater into surface water will decline over time (Geosyntec Consultants, Inc., 2017). The source control approach removes the amount of water retained within the impoundment, which further reduces the hydraulic flux through the CCR. Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS would also be controlled and minimized. As demonstrated by the groundwater modeling in support of the Closure Plan, Source Control would result in a significant reduction in groundwater concentrations and, overtime, reduce the extent of groundwater impacts to within the footprint of the impoundment (Geosyntec Consultants, Inc., 2017).

Under the Source Control-GWP alternative, minimal surface water and sediment impacts would be expected to be associated with residual plume management because it would not require the construction of any engineered systems or structures (other than utilizing existing monitoring wells).

Under the Source Control-CCS alternative, surface water and sediment impacts would be higher than the Source Control-GWP alternative due to the construction of the cutoff wall. Due to erosion and runoff, construction can have short-term negative impacts on surface water and sediment quality immediately adjacent to a site. Any associated impacts would be addressed through best management practices (BMPs) in accordance with Site land disturbance permits.

2.2.5.4 Control of Exposure to Any Residual Contamination During Implementation of the Remedy

Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further risks of CCR exposure associated with source control implementation. However, impacted soils and groundwater can be a source of CCR-related constituent exposure for workers. Risks to workers arising from potential contact with residual contamination during construction activities associated with residual plume management would be higher for the Source Control-CCS alternative than for the Source Control-GWP alternative, because the Source Control-CCS alternative would involve removal of a portion of the previously installed final cover system and excavation and subsequent disposal of Site spoils. In contrast, the Source Control-GWP alternative would not involve exposure to either of these soil or groundwater waste streams. Any potential CCR-exposures during the Source Control-CCS alternative would be managed through the use of rigorous safety protocols and personal protective equipment.

2.2.5.5 Other Identified Impacts

Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further risks associated with source control implementation.

In addition to safety impacts, cross-media impacts, and the potential for workers to be exposed to residual contamination, construction activities and remedial operations can have significant energy demands and can cause nuisance impacts such as traffic and noise. Energy consumption at a construction site is synonymous with fossil fuel consumption, because the energy to power construction vehicles and

equipment comes from the burning of fossil fuels. Fossil fuel demands considered here include the burning of diesel fuel during construction equipment and vehicle travel miles. Because GHG emission impacts and energy consumption impacts both arise from the same sources at construction sites, the trends discussed in Section 2.2.5.2 with respect to GHG emissions also apply to the evaluation of energy demands. Specifically, the energy demands of construction equipment and vehicles associated with residual plume management would be greater under the Source Control-CCS alternative, while the energy demands under the Source Control-GWP alternative associated with residual plume management are expected to be lower because this alternative would not require any significant construction activity. There is no operational energy expected under either of the alternatives, because the Source Control-GWP alternative would rely on physical and geochemical processes, while the Source Control-CCS alternative would rely on the constructed barrier wall.

Similarly, traffic and noise impacts associated with residual plume management are expected to be higher under the Source Control-CCS alternative than the Source Control-GWP alternative, due to the construction activities that would be required to construct the barrier wall. Traffic may increase temporarily around the Site under these alternatives due to the daily arrival and departure of the workforce, equipment mobilization/demobilization, and material deliveries. However, these impacts would be expected to largely occur at the beginning or end of each workday (for the arrival/departure of the work force), at the beginning or end of the construction period (for equipment mobilization/demobilization), and at specific times throughout the construction period (for material deliveries). Traffic and noise impacts associated with residual plume management from the Source Control-GWP are expected to be minimal due to the limited amount of construction and operation of the groundwater monitoring wells required.

Construction activities can negatively impact natural resources and habitat near the Site, as well as scenic, historical, and recreational value. Based on a review of the Illinois Department of Natural Resources (IDNR) Historic Preservation Division database and the Illinois State Archaeological Survey database, there are no historic sites located within 1,000 meters of the WAPS (Ramboll, 2021). There would be no impacts under the Source Control-GWP alternative because no additional construction activities would occur. However, negative impacts resulted from construction activities on scenic and recreational value may occur along the Illinois River and within the Donnelley/DePue State Fish and Wildlife Areas complex, under the Source Control-CCS alternative. The Donnelley/DePue State Fish and Wildlife Areas border the Hennepin Site to the north and west and includes DePue Lake, Spring Lake, and Coleman Lake. Under the Source Control-CCS, large cranes, batch plants, and other equipment could be utilized during construction phases. The Illinois River is popular for canoeing and other forms of water recreation (IDNR, 2021). Given the proximity between these areas and the expected construction, it is likely that these areas would experience some adverse impacts such as visual disturbance, obstruction of view, and noise during the construction period. However, these impacts are expected to diminish once the construction is completed in 18 to 24 months for the Source Control-CCS alternative.

In addition, the construction of the cutoff wall under the Source Control-CCS alternative is expected to use a significant amount of cement or bentonite, which would be introduced into the UA and the BCU. The process would use bentonite-based drilling mud with various additives, similar to the methods employed in well drilling but on a notably larger scale. Adding substantial quantities of these materials into the subsurface environment may cause alteration in groundwater pH levels and affect geochemical conditions in the UA.

2.2.6 Time Until Groundwater Protection Standards Are Achieved/Attain the Groundwater Protection Standards Specified in Section 845.600 (IAC Section 845.670(e)(1)(E)/IAC Section 845.680(d)(2))

This section of the report evaluates the time required to achieve GWPSs, pursuant to requirements under IAC Section 845.670(e)(1)(E) (IEPA, 2021) and under IAC Section 845.680(d)(2).

The groundwater movement in the unconsolidated materials is consistent with surface topography and flows north and west near the Site towards the Illinois River, which serves as a large regional hydraulic boundary. Precipitation infiltration recharges groundwater. Under normal post-closure conditions, groundwater flows northward toward the river at the WAPS (Appendix B; Ramboll, 2025b).

The source control activities were completed in 2020. Groundwater modeling was performed in support of the Closure Plan (Geosyntec Consultants, Inc., 2017). The modeling predicted that source control would result in the reduction of leachate production, which facilitates the contraction of the contaminant plume in groundwater (Geosyntec Consultants, Inc., 2017). Additional modeling was conducted for each of the corrective action alternatives to evaluate future groundwater quality in the vicinity of the WAPS as a result of residual plume management (Appendix B; Ramboll, 2025b). The results of the modeling and subsequent evaluation (Appendix E; Geosyntec Consultants, Inc., 2025) indicate that groundwater would attain the GWPSs for all of the constituents[8] identified as having potential groundwater exceedances in the groundwater monitoring network within 29 years under the Source Control-GWP alternative and 38 to 40 years under the Source Control-CCS alternative (5 to 7 years of pre-construction and construction activities followed by 33 years post-construction).[9] Both alternatives are assumed to start after approval of the Corrective Action Plan (Appendix B; Ramboll, 2025a). Table 2.5 summarizes and compares timeline and overall implementation schedule for both alternatives (also discussed in Sections 2.1.1 and 2.1.2).

[8] Boron was selected as a surrogate for the contaminant fate and transport simulations to evaluate the effectiveness of each of the corrective action alternative. Boron was detected in the greatest number of WAPS groundwater wells exceeding its GWPS, a statistically significant correlation has been identified between observations of boron in groundwater and observations of lithium and sulfate in groundwater and boron is expected to take the longest time to achieve GWPS. Modeling all constituents that exceed GWPS or have been detected at lower concentrations relative to their GWPSs is unnecessary, as these constituents will likely achieve their GWPSs more quickly (Appendix B; Ramboll, 2025).

[9] As suggested by the site-specific evaluations, some arsenic re-mobilization may occur as groundwater returns to background conditions at the Site, which may cause an impact and result uncertainty to the time to achieve GWPS (Section 2.1.1; Appendix E; Geosyntec Consultants, Inc., 2025).

Table 2.5 Estimated Timeline and Implementation Schedule for Source Control-GWP *vs.* Source Control-CCS

Implementation Phase[a]	Implementation Task	Timeframe	
		Source Control-GWP	Source Control-CCS
1: Pre-Construction Activities[a]	Agency Coordination, Approvals, and Permitting	NA	18 to 24 months
	Final Design and Bid Process		24 to 36 months
	Total Timeframe to Complete Corrective		42 to 60 months after CAP Approval (3.5 to 5 years)
	Pre-Construction Activities		
2: Corrective Action Construction	Corrective Action Construction	NA	18 to 24 months
	Total Timeframe to Complete Corrective Action Construction		18 to 24 months
3: Corrective Action O&M and Closeout	Corrective Action Monitoring (Time to Meet GWPS)	348 months (29 years)	396 months (33 years)
	Corrective Action Confirmation Monitoring	36 months	36 months
	Corrective Action Completion Reporting	6 months	6 months
	Total Timeframe to Complete Corrective Action O&M and Closeout	390 months (33 years)	438 months (36.5 years)
Total Timeline to Complete Corrective Action (All Phases)		390 months (33 years)	498 to 522 months (42 to 44 years)

Notes:
CAP = Corrective Action Plan; NA = Non-applicable; Source Control-CCS = Source Control with Continuous Containment System; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Both corrective action alternatives are assumed to start after the approval of the corrective action plan.
Source: Appendix B; Ramboll, 2025a.

2.2.7 Potential for Exposure of Humans and Environmental Receptors to Remaining Wastes, Considering the Potential Threat to Human Health and the Environment Associated with Excavation, Transportation, Re-disposal, Containment, or Changes in Groundwater Flow (IAC Section 845.670(e)(1)(F))

Section 2.2.1 describes the magnitude of reduction of existing risks under each corrective action alternative. Section 2.2.2 describes the effectiveness of the remedy in controlling the source, including the extent to which containment practices would reduce further releases. Section 2.2.3 describes the likelihood of future releases of CCR occurring under each corrective action alternative, and Section 2.2.5 describes the short-term risks to workers, the community, and the environment during implementation of the remedy, including safety impacts and control of exposure to any residual contamination. In summary, source control measures (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, both corrective action alternatives would essentially eliminate the potential for a sudden CCR release to occur post-closure (*e.g.*, a dike failure event) due to the absence of both impounded water within the unit, and are equally and fully protective with regard to exposure to residual CCR.

For construction workers, risks arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be higher for the Source Control-CCS alternative than for the Source Control-GWP alternative, because the Source Control-CCS alternative would involve the excavation and subsequent management of Site spoils.

In addition, Source Control-CCS would involve temporarily removing a portion of the final cover previously installed, which could potentially allow stormwater to be in contact with CCR material during construction. CCR-contact stormwater would be generated and managed through CCR-contact stormwater management system under this alternative while a portion of the final cover would be removed. Any potential CCR exposures occurring under Source Control-CCS during the installation of the cutoff would be managed through the use of rigorous safety protocols, personal protective equipment, and appropriate disposal practice. The Source Control-GWP alternative would not involve exposure to either of these soil or groundwater waste streams and thus, there is no potential for exposure of humans and environmental receptors to wastes.

Hydrogeological changes would be expected under the Source Control-CCS alternative, such as altering flow patterns in the UA, redirecting groundwater flow around the cutoff wall, and causing changes to normal hydraulic gradients. However, changes to groundwater flow would not be expected to have an effect on the potential for the exposure of humans and environmental receptors to any wastes.

2.2.8 Long-Term Reliability of the Engineering and Institutional Controls (IAC Section 845.670(e)(1)(G))

Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, the long-term reliability of source control would be the same for both corrective action alternatives (Geosyntec Consultants, Inc., 2017). The long-term reliability of the engineering and institutional controls associated with residual plume management of each corrective action alternative are summarized below.

- Residual plume management under the Source Control-GWP alternative would be reliable because it would rely on physical and geochemical processes, rather than the installation, operation, and maintenance of engineered systems or structures. Under this alternative, engineering failure would not occur and no O&M activities would be required to ensure the success of the alternative (other than those required for groundwater monitoring). Active groundwater monitoring would be in place to track the remediation progress. Should the predicted decrease in groundwater concentrations not occur, the adaptive site management approach would enable prompt adjustments or enhancements to the corrective action in accordance with IAC Section 845.680(b). This strategy would allow continuous improvement of the WAPS groundwater remediation in response to new Site information and/or the performance of the corrective action alternative.
- Cutoff walls are proven remedies that have been implemented at many sites. Thus, residual plume management under the Source Control-CCS alternative would be reliable provided it is constructed in accordance with standard design and specifications. The remedy consists of a passive, below-grade physical barrier, which would not require any O&M activities once it is installed. The final cover system would require ongoing maintenance per existing Post-Closure Care Plan but is a durable, engineered structure. Some challenges are expected during construction, necessitating specialized equipment deployment. Since the cutoff wall would be installed through an existing impoundment embankment, additional engineering assessments and monitoring programs would be necessary to the embankment for indications of distress, such as deformation or cracking, throughout the cutoff wall construction process. Appropriate measures would be taken to stabilize the embankment if instability is detected. The construction of the cutoff wall would require temporarily removing a portion of the previously installed WAPS final cover. This procedure may allow additional stormwater to infiltrate the CCR, potentially leading to a temporary reversal of some positive effects that have occurred since the completion of the final cover system in 2020. A CCR-contact stormwater management system would be required to manage and discharge the contact stormwater *via* an NPDES permitted outfall. The effectiveness of the cutoff wall relies on precise construction techniques, demanding ongoing QC. Other challenges include the

management of the temporary removal of the already finished final cover system, which would require a contact stormwater management system during this time. However, post-construction QA programs may be required to validate the quality of the constructed cutoff wall. Ongoing monitoring of the system may be required to ensure reliable operation. Active groundwater monitoring would be in place, similar to the monitoring required under the Source Control-GWP alternative.

- For both corrective action alternatives, remedy optimizations would be implemented if necessary under the adaptive site management.

2.2.9 Potential Need for Replacement of the Remedy (IAC Section 845.670(e)(1)(H))

The potential need for the eventual replacement of the residual plume management remedy under each corrective action alternative is summarized as follows:

- Residual plume management under Source Control-GWP would rely on physical and geochemical processes to achieve reductions in groundwater concentrations to below GWPSs. Because no installation, operation, and maintenance of engineered systems or structures would be required, it would be unlikely that the residual plume management remedy under the Source Control-GWP alternative would need to be replaced. Adaptive site management strategies would be used to implement remedy optimizations or replacement, as necessary based on data that are collected, to ensure that remedial goals are achieved.
- Residual plume management under Source Control-CCS would rely on a cutoff wall as a physical barrier to contain the CCR mass within the WAPS and achieve reductions in groundwater concentrations to below GWPSs. The deep cutoff wall is a robust, engineered, and maintenance-free subsurface structure. The final cover system portion of this alternative would need ongoing maintenance per the IEPA approved Post-Closure Care Plan, but it is a passive and engineered structure that is unlikely to need replacement. Therefore, it is unlikely that the residual plume management remedy under the Source Control-CCS alternative would need to be replaced. Adaptive site management strategies would be used to implement remedy optimizations or replacement, as necessary based on data that are collected, to ensure that remedial goals are achieved.

2.3 The Ease or Difficulty of Implementing a Remedy (IAC Section 845.670 (e)(3))

2.3.1 Degree of Difficulty Associated with Constructing the Remedy (IAC Section 845.670(e)(3)(A))

Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there would be no further construction difficulties associated with source control. The expected degree of difficulty associated with residual plume management for each of the corrective action alternatives is summarized below.

- Residual plume management under the Source Control-GWP alternative would rely on physical and geochemical attenuation processes and therefore would not pose any significant construction

challenges. Therefore, there would be minimal difficulty in constructing the Source Control-GWP remedy.

- Residual plume management under the Source Control-CCS alternative would rely on a continuous containment system to enclose the CCR within the WAPS, and physical and geochemical attenuation processes to address downgradient groundwater quality impacts. However, it may have the following challenges during construction of the cutoff wall (Appendix B; Ramboll, 2025a):
  - Implementing the remedy entails the mobilization of specialized equipment to the Site, including large cranes, clamshells, and slurry cutters, *etc*. Supporting equipment such as batch plants, excavation, and grading equipment may also be used.
  - Although cutoff walls are commonly constructed to similar depths in comparable geologic environments, challenges during the cutoff wall's construction may still arise. These challenges may involve encountering highly permeable layers (leading to slurry loss), obstructions that necessitate specialized techniques and/or equipment for progression, or sidewall instability. These challenges could be particularly significant at the WAPS due to the presence of boulders and cobbles in the subsurface soils. While these challenges could be managed during cutoff wall construction, they may lead to potential schedule delays.
  - The cutoff wall would be installed through an existing impoundment embankment, which is a dam regulated by IDNR. Therefore, additional engineering assessments and monitoring programs would be necessary to monitor the embankment for indications of distress, such as deformation or cracking, throughout the cutoff wall construction process. Appropriate measures would be taken to stabilize the embankment if instability is detected.
  - The construction of the cutoff wall would require temporarily removing a portion of the previously installed WAPS final cover in areas where conflict with the cutoff wall. This procedure may allow additional stormwater to infiltrate the CCR, potentially leading to a temporary reversal of some positive effects that have occurred since the completion of the final cover system in 2020. A CCR-contact stormwater management system would be required to manage and discharge the contact stormwater *via* an NPDES permitted outfall.
  - The effectiveness of the cutoff wall relies on the construction techniques employed to prevent gaps, voids, or other discontinuities in the structure. Ongoing QC is essential during construction as part of QA activities to prevent such defective features. Additionally, QA programs, such as coring and testing, may be necessary to validate the quality of the constructed barrier.
  - The performance of the wall is contingent on its actual hydraulic conductivity. This necessitates ongoing monitoring and QA/QC testing for slurry mixing, placement, or soil-bentonite mixing. The goal is to ensure adherence to the designed mix and involves routine testing of samples from the wall material.

2.3.2 Expected Operational Reliability of the Remedy (IAC Section 845.670(e)(3)(B))

Source control (*i.e*., CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, the operational reliability of the remedy would be the same for both corrective action alternatives. Both corrective action alternatives would likely be highly reliable with respect to operational controls associated with residual plume management; specific details for each corrective action alternative are discussed below.

- Residual plume management under the Source Control-GWP alternative would have high operational reliability because it would rely on physical and geochemical processes and active

monitoring, rather than the installation, operation, and maintenance of engineered systems or structures (other than monitoring wells). Under the Source Control-GWP alternative, engineering failure would not occur, and no O&M activities would be required to ensure the success of the alternative. However, it should be noted that some arsenic re-mobilization may occur as groundwater returns to background conditions at WAPS, which may cause an impact to the time to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025).

- Residual plume management under the Source Control-CCS alternative would also have high operational reliability, because it is an established remedial technology, as long as it is constructed in accordance with standard design specifications for barrier walls, and the final cover system is maintained according to the existing Post-Closure Care Plan. This continuous containment system would provide full lateral (*i.e.*, through the deep cutoff wall), surface (*i.e.*, through the existing cover) isolation of CCR from the surrounding environment. The wall would be keyed into competent shale bedrock to provide additional subsurface containment below the WAPS. However, the remedy would require the temporary removal of a portion of the completed cover over the WAPS and potentially cause additional stormwater to percolate into the CCR and result in a temporary reversal of certain positive effects that have occurred since the completion of source control in 2020. These temporary impacts would diminish once the final cover system is repaired, and the continuous containment system would be present.
- Adaptive site management strategies would be used to implement remedy optimizations, if necessary under both corrective action alternatives.

2.3.3 Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies (IAC Section 845.670(e)(3)(C))

Both corrective action alternatives would require regulatory approvals. Specific permits and approvals associated with source control were the same for both corrective action alternatives and were discussed in the Closure Plan (Geosyntec Consultants, Inc., 2017). The specific approvals and permits associated with residual plume management for both corrective action alternatives are discussed below.

- The Source Control-GWP alternative would not need additional permits from other agencies, other than the approval of the eventual Corrective Action Plan.
- The Source Control-CCS alternative would require approvals and permits, including construction stormwater controls and BMPs, a joint water pollution control construction and operating permit. An IDNR Dam Safety modification permit would also be required for modifications of the WAPS embankment. A modification to the existing NPDES permit would be necessary to discharge the CCR-contact stormwater generated during the construction phase. These permits and plans typically take 18 to 24 months to obtain.

2.3.4 Availability of Necessary Equipment and Specialists (IAC Sections 845.670(e)(3)(D) and 845.660(c)(1), "Ease of Implementation")

Source control (*i.e.*, CIP using a consolidate-and-cap approach) was implemented in 2020. Thus, there are no further equipment and specialist needs associated with the implementation of the source control remedy. Specialized equipment and personnel are essential for field data collection and groundwater sampling for residual plume management under both potential corrective action alternatives. Additionally, the assessment of groundwater concentrations for Site constituents would necessitate laboratory equipment and

specialists for both alternatives. The availability of equipment and specialists for each corrective action alternative is summarized below.

- Residual plume management under the Source Control-GWP alternative would require groundwater professionals, such as geologists, hydrogeologists, statisticians, and geochemists to conduct statistical analyses, ensuring that natural geochemical processes functions as anticipated in this alternative. The equipment and specialists needed for Site groundwater monitoring and analysis are currently engaged in these tasks as part of the routine groundwater monitoring program outlined in accordance with IAC Section 845.220(c)(4).
- Residual plume management under the Source Control-CCS alternative would require specialists for the construction phase of the cutoff wall.
    - Building the cutoff wall requires the expertise of a specialized contractor with a background in constructing similar types of walls in comparable geologic environments, like those found in the Illinois, Mississippi, and Ohio River Valleys. The contractor would probably need specialized equipment, including large cranes, clamshell buckets, slurry cutters, batch plants, or other equipment.
    - Specialists involved in the design and construction of cutoff walls would be essential during both phases. This team of specialists should include design engineers, construction managers, and contractor staff with expertise in cutoff wall construction and equipment operation.
    - Monitoring the WAPS embankments during cutoff wall construction would require expertise in geotechnical instrumentation, including the use of inclinometers, survey prisms, vibrating wire piezometers, and visual inspection for signs of distress. Specialized drilling and installation contractor would be needed to construct the geotechnical instrumentation system.
    - The types of equipment and specialists should have been employed for projects similar to designing and building cutoff walls. However, there may be backlogs associated with the equipment and specialists, due to the high existing demand for specialty ground improvement contractors and design specialists who are engaged with similar projects in sectors like electric utilities, dams/levees, and other areas.
    - Equipment and experts with geosynthetics design and installation, specifically with seaming new geosynthetics to an existing final cover system, would be required for the final cover system restoration. However, the experts and equipment's availability could be limited due to the high existing backlog due to ongoing projects in the solid waste management, electric utility, and other areas.
    - This alternative would also require the use of equipment and the expertise of specialists for tasks such as field data collection, groundwater sampling, groundwater sample analysis, and periodic corrective action groundwater monitoring and reporting. Similar to those in the Source Control-GWP alternative, these activities are already being conducted as part of routine groundwater monitoring in accordance with IAC Section 845.220(c)(4).

2.3.5 Available Capacity and Location of Needed Treatment, Storage, and Disposal Services/Comply with Standards for Management of Wastes as Specified in Section 845.680(d) (IAC Section 845.670(e)(3)(E)/IAC Section 845.670(d)(5))

The available capacity and location of needed treatment, storage, and disposal services associated with residual plume management under each corrective action alternative is summarized below. All the practices employed in the three alternatives would comply with standards for the management of wastes as specified in IAC Section 845.670(e)(3)(E) and IAC Section 845.680(d)(5).

- Residual plume management for the Source Control-GWP remedy would not require any treatment, storage, or disposal services, because groundwater polishing (GWP) is not anticipated to produce a substantial amount of waste or wastewater, aside from minor purge water volumes generated during routine groundwater sampling activities for residual plume management. This could be managed by a standard waste management contractor.
- Residual plume management for the Source Control-CCS alternative would generate waste during the cutoff wall construction phase, which would include geosynthetics and other debris from removing the final cover system, cutoff wall spoils and contact stormwater.
    - Geosynthetics and other debris would be disposed of in an off-Site landfill that has sufficient volume to receive the relatively small amount of waste materials.
    - CCR-impacted cutoff wall spoils would be temporarily staged on-Site and then disposed either off-Site or beneficially used on-Site as compacted contouring fill beneath the East Ash Pond final cover system. The later disposal would require coordination with the East Ash Pond closure activities.
    - Non CCR-impacted spoils would be disposed of at an appropriate on-Site location.
    - CCR-contact stormwater generated during construction would be pumped to the on-Site treatment pond and then discharged *via* an NPDES permitted outfall.
    - No wastes would be expected to be generated after the cutoff wall is installed, and consequently, no additional treatment, storage, or disposal services would be necessary for this remedy.

2.4 The Degree to Which Community Concerns Are Addressed by the Remedy (IAC Section 845.670(e)(4))

Several nonprofits raised concerns regarding the potential impacts of the WAPS on groundwater and surface water quality (Earthjustice *et al*., 2018; Sierra Club and CIHCA, 2014). The combination of source control (*i.e*., CIP using a consolidate-and-cap approach) and residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Geosyntec Consultants, Inc., 2017; Appendix B; Ramboll, 2025b), thus addressing these concerns.

A public meeting was held on April 8, 2025, pursuant to requirements under IAC Section 845.710(e). Questions raised by attendees were answered at the meeting; a written summary of the questions and responses were prepared.

2.5 Remove from the Environment as Much of the Contaminated Material that Was Released from the CCR Surface Impoundment as Is Feasible, Taking into Account Factors such as Avoiding Inappropriate Disturbance of Sensitive Ecosystems (IAC Section 845.670(d)(4))

There have been no known releases of CCR at the WAPS (Ramboll, 2025d). Both potential corrective action alternatives include source control and would have residual plume management efforts. The source control included the consolidation of CCR excavated from the OWPP into the OWAP portion of the WAPS

and the installation of a low-permeability final cover system designed to limit the infiltration of precipitation into the impounded CCR. Groundwater modeling was performed in support of the Closure Plan (Geosyntec Consultants, Inc., 2017) predicted that source control would result in the reduction of leachate production, a decrease in CCR leachate constituent concentrations, and a contraction of the groundwater contaminant plume (Geosyntec Consultants, Inc., 2017). Due to the reduction in the hydraulic flux out of the WAPS, the mass flux out of the WAPS would also be controlled. Therefore, source control is preventing further releases of CCR constituents into the environment.

Moreover, residual plume management under each corrective action alternative will further result in the removal of contaminated material from the environment and/or the improvement of downgradient groundwater quality. Groundwater modeling has predicted that GWPSs would be achieved in all monitoring wells within 29 years, and 38 to 40 years (33 years as suggested by groundwater modeling and 5 to7 years of pre-construction under the Source Control-GWP and Source Control-CCS alternatives, respectively, assuming both alternatives start after approval of the corrective action plan) (Appendix B; Ramboll, 2025a). Specific considerations for residual plume management for each alternative are provided below.

- Residual plume management under the Source Control-GWP alternative would address impacted groundwater by relying on physical and geochemical attenuation processes to reduce the residual concentrations of CCR. Site-specific evaluations have shown that groundwater polishing would reduce the groundwater concentrations and mobility of inorganic contaminants (including boron and sulfate), through physical and geochemical attenuation mechanisms, especially after the implementation of source control (Appendix E; Geosyntec Consultants, Inc., 2025). However, it should be noted some arsenic re-mobilization may occur as groundwater returns to background conditions at WAPS, which may cause an impact to the time required to achieve GWPS (Appendix E; Geosyntec Consultants, Inc., 2025). In cases in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques would be evaluated under the adaptive site management, and if viable, incorporated as per IAC Section 845.680(b). No ecosystems would be disturbed because no construction activities are expected under the Source Control-GWP alternative.
- Residual plume management under the Source Control-CCS alternative would employ the cutoff wall which would be incorporated into the final WAPS cover system to create a continuous low-permeability barrier that fully contains the CCR within the WAPS. This system ensures isolation from the surrounding environment through lateral containment by the deep cutoff wall, surface containment by the existing geomembrane cover, and a natural barrier provided by the competent shale bedrock below. The temporary removal of a portion of the final cover system implemented during closure in 2020 would occur during construction, which would generate CCR-contact stormwater that would be managed appropriately. These construction activities may cause some negative impacts on natural resources and habitat located atop the WAPS final cover system and near the Site. However, the total duration of the construction is expected to be 18 to 24 months, so any construction-related impacts to ecosystems would be limited to the short term and would diminish once construction is completed.
- Although both corrective action alternatives include source control and residual plume management, Source Control-CCS would be more effective at controlling sources of releases than Source Control-GWP for the WAPS.

2.6 Summary

This CAAA evaluates both corrective action alternatives identified as potentially viable in the CMA with regard to each of the factors specified in IAC Section 845.670(d) and 845.670(e) (IEPA, 2021). Based on this evaluation, the most appropriate corrective action for this Site is Source Control-CCS.

Although the expected impacts on workers, nearby communities, and the environment under the Source Control-GWP alternative are lower than the Source Control-CCS alternative, the Source Control-CCS alternative would provide full containment of the CCR within WAPS and be more effective at controlling sources of releases than Source Control-GWP. Controlling the source of releases using CCS is particularly important at this Site because of the high groundwater transmissivity associated with the sands and gravels in the UA. Thus, Source Control-CCS is the most appropriate corrective action alternative for the WAPS.

1 Introduction

Dynegy Midwest Generation (DMG) Company's Hennepin Power Plant (HPP, or "the Site") is an electric power-generating facility with coal-fired units located in Hennepin, Illinois. The facility began operations in the early 1950s and was retired in 2019 (Ramboll, 2021). The HPP produced and stored coal combustion residuals (CCRs) as a part of its historical operations in several CCR ash ponds. Ponds located east of the power plant include East Ash Pond No. 2, East Ash Pond No. 4, East Ash Pond, Leachate Pond, and Polishing Pond. The West Ash Pond System (WAPS) consists of the Old West Ash Pond (OWAP, which includes Pond No. 1 and Pond No. 3) and Old West Polishing Pond (OWPP) (Vistra identification [ID] number [No.] 804, Illinois Environmental Protection Agency [IEPA] ID No. W1550100002-01 and W1550100002-03), and is the subject of this report.

This report presents the results of an evaluation that characterizes potential risk to human and ecological receptors that may be exposed to CCR constituents in environmental media potentially impacted by the WAPS. This risk evaluation was performed to support the Corrective Action Alternative Analysis (CAAA) for the WAPS in accordance with requirements in Title 35 Part 845.670 of the Illinois Administrative Code (IAC) (IEPA, 2021). Human and ecological risks were evaluated for Site-specific constituents of interest (COIs). The conceptual site model (CSM) assumed that Site-related COIs in groundwater may migrate to the Illinois River and affect surface water and sediment in the vicinity of the Site.

Consistent with United States Environmental Protection Agency (US EPA) guidance (US EPA, 1989), this report uses a tiered approach to evaluate potential risks, including the following steps:

1. Identify complete exposure pathways and develop a conceptual exposure model (CEM).
2. Identify Site-related COIs: Constituents detected in groundwater were considered COIs if their maximum detected concentration over the period from 2015 to 2021 exceeded a groundwater protection standard (GWPS), identified in Part 845.600 (IEPA, 2021), or a relevant surface water quality standard (IEPA, 2019a; US EPA Region IV, 2018).
3. Perform screening-level risk analysis: Compare maximum measured or modeled COI concentrations in surface water and sediment to conservative, health-protective benchmarks to determine constituents of potential concern (COPCs).
4. Perform refined risk analysis: If COPCs are identified, perform a refined analysis to evaluate potential risks associated with the COPCs.
5. Formulate risk conclusions and discuss any associated uncertainties.

This assessment relies on a conservative (*i.e.*, health-protective) approach and is consistent with the risk approaches outlined in US EPA guidance. Specifically, we considered evaluation criteria detailed in IEPA guidance documents (*e.g.*, IEPA, 2013, 2019a), incorporating principles and assumptions consistent with the Federal CCR Rule (US EPA, 2015a) and US EPA's "Human and Ecological Risk Assessment of Coal Combustion Residuals" (US EPA, 2014).

US EPA has established acceptable risk metrics. Risks above these US EPA-defined metrics are termed potentially "unacceptable risks." Based on the evaluation presented in this report, no unacceptable risks to human and ecological receptors resulting from CCR exposures associated with the WAPS were identified. Specific risk assessment results include the following:

- No completed exposure pathways were identified for any groundwater receptors; consequently, no risks were identified relating to the use of groundwater.
- No unacceptable risks were identified for recreators swimming or boating in the Illinois River adjacent to the Site.
- No unacceptable risks were identified for recreators exposed to sediment in the Illinois River adjacent to the Site.
- No unacceptable risks were identified for anglers consuming locally caught fish.
- No unacceptable risks were identified for ecological receptors exposed to surface water or sediment.
- No bioaccumulative ecological risks were identified.

It should be noted that this evaluation incorporates a number of conservative assumptions that tend to overestimate exposure and risk. Moreover, it should be noted that because current conditions do not present a risk to human health or the environment, there will also be no unacceptable risk to human health or the environment for future conditions because the WAPS was already closed in 2020. For all future closure scenarios, potential releases of CCR-related constituents will decline over time and consequently potential exposures to CCR-related constituents in the environment will also decline.

2 Site Overview

2.1 Site Description

The HPP is located four miles northeast of the Village of Hennepin in north central Illinois in Putnam County. The HPP property is bordered on the north by the Illinois River, on the south and east by industrial properties, and on the west by agricultural land. The Illinois River flows past the facility from east to west.

The CCR ash ponds located to the west of the power plant include the OWAP and the OWPP, collectively known as the WAPS (OBG, 2019) (Figure 2.1). The WAPS was closed in 2020 using closure-in-place (CIP) with a consolidate-and-cap approach, which included "removal of CCR and dike soils in the OWPP and consolidation of these materials into the OWAP" (OBG, 2019), and "capping [the OWAP] with a geosynthetic and soil final cover system" (Ramboll, 2025a). The WAPS is the subject of this report.

2.2 Geology/Hydrogeology

The geology underlying the Site in the vicinity of the WAPS consists of unlithified deposits of the Cahokia Alluvium and the Henry Formation, underlain by a thick shale bedrock (NRT, 2017; OBG, 2019). The Cahokia Alluvium consists of fine-grained silt, clay, and sand, whereas the underlying Henry Formation is composed of highly permeable sand and gravel (NRT, 2017; OBG, 2019). The Cahokia Alluvium deposits are absent in the eastern portion of the WAPS; in this area, the WAPS lies directly over Henry Formation (OBG, 2019). The thickness of the Cahokia Alluvium in the western part of the WAPS ranges from 10 to 40 ft (NRT, 2017). The Henry formation ranges from 5 to 35 ft thick (NRT, 2017).

Three distinct hydrostratigraphic units have been identified in the area near the WAPS (NRT, 2017; OBG, 2019):

- **Fill Unit:** The Fill Unit directly underlies the WAPS. It is comprised primarily of fly ash, with small amounts of bottom ash and slag mixed with sand, silt, and clay. During closure of the OWPP in 2020, CCRs in the ash pond and one foot of soils below the ash pond were removed.
- **Uppermost Aquifer Unit (UAU):** The UAU is comprised of mixed alluvial deposits (classified as Cahokia alluvium consisting of clay, silt, and sand) and coarser grained outwash sand and gravel deposits (classified as Henry Formation).
- **Bedrock Confining Unit (BCU):** The BCU consists of Pennsylvanian age shale bedrock with minor layers of limestone, sandstone, and coal. This low permeability unit defines the lower boundary of the Uppermost Aquifer Unit at the WAPS.

The Illinois River, located less than 0.1 mile north of the WAPS, is the major surface water body in the area. Groundwater in the UAU predominantly flows to the north/northwest, consistent with the surface topography, into the Illinois River (OBG, 2019). Prior to the closure during the impoundment operations, substantial local recharge to groundwater from sluicing of ash created radial flow conditions near the Site (Ramboll, 2025a). A groundwater flow reversal (*i.e.*, groundwater flows in a south to southwest direction toward the wetlands) may occur during high river stages or flooding events when the Illinois River stage elevation is higher than surrounding groundwater elevations. The normal horizontal hydraulic gradient

near the WAPS is approximately 0.005 ft/ft (NRT, 2017; OBG, 2019). Under normal post-closure conditions, groundwater flows northward toward the river from the WAPS (Ramboll, 2025a). The low permeability bedrock aquitard acts as a barrier to downward migration of groundwater from the UAU (NRT, 2017).

2.3 Conceptual Site Model

A CSM describes sources of contamination, the hydrogeological units, and the physical processes that control the transport of water and solutes. In this case, the CSM describes how groundwater underlying the WAPS migrates and interacts with surface water and sediment in the adjacent Illinois River. The CSM was developed using available hydrogeological data (NRT, 2017; OBG, 2019; USGS, 2021a; Tetra Tech, 2012), including information on groundwater flow and surface water characteristics.

The highly permeable Henry Formation of the UAU, consisting of sands and gravels, is the primary conduit for groundwater flowing into the Illinois River (Ramboll, 2021). The downward groundwater migration from the UAU to underlying units is significantly limited due to the presence of thick, low-permeability shale bedrock, which acts as a confining layer (NRT, 2017). Other than flow into the Illinois River, no other potential groundwater transport pathways have been identified for the UAU (NRT, 2017). Because the Illinois River is a large regional hydraulic boundary (*i.e.*, serves as a sink for groundwater discharges in the area), all shallow groundwater underlying the WAPS is expected to flow into the river.

Near the WAPS, groundwater flowing into the Illinoi River mixes with surface water. During mixing, dissolved constituents in groundwater may partition between sediments and surface water.

Figure 2.1 Site Location Map. Source: Ramboll (2025b).

2.4 Groundwater Monitoring

Thirteen wells screened in the UAU have been used to monitor the groundwater quality near and downgradient of the WAPS (Table 2.1). The analyses presented in this report relied on all available data from the 13 wells collected between 2018 and 2023. Groundwater samples were analyzed for a suite of metals, both total and dissolved, specified in Illinois CCR Rule Part 845.600 (IEPA, 2021).[1] A summary of the groundwater data used in this risk evaluation is presented in Table 2.2. The WAPS-related well locations are shown in Figure 2.2. The use of groundwater data in this risk evaluation does not imply that detected constituents are associated with the WAPS or that they have been identified as potential groundwater exceedances.

[1] Samples were analyzed for a longer list of inorganic constituents and general water quality parameters (chloride, fluoride, sulfate, and total dissolved solids), but these constituents were not evaluated in the risk evaluation.

2.5 Surface Water Monitoring

Surface water samples were collected at 15 locations in September 2020 and one location in February 2021 in the Illinois River adjacent to the HPP. The 2020 samples were collected along five transects, with three samples per transect collected from the two edges and the center of the river (Figure 2.3). Sample set IR-01 was collected approximately one mile upstream of the HPP. Sample sets IR-02, IR-03, and IR-04 and IR-05 were located upstream of the WAPS, and set IR-05 was located downstream of the WAPS. Sample SG02 (February 2021) was located adjacent to the plant (Figure 2.3). It should be noted that many constituents occur naturally in the environment and/or could be associated with industrial activities unrelated to the WAPS. The use of surface water data in this risk assessment does not imply that any constituents are associated with the WAPS. A summary of the surface water data used in this risk evaluation is presented in Table 2.3.

3 Risk Evaluation

3.1 Risk Evaluation Process

A risk evaluation was conducted to determine whether constituents present in groundwater underlying and downgradient of the WAPS have the potential to pose adverse health effects to human and ecological receptors. The risk evaluation is consistent with the principles of risk assessment established by US EPA and has considered evaluation criteria detailed in Illinois guidance documents (*e.g.*, IEPA, 2013, 2019a).

The general risk evaluation approach is summarized in Figure 3.1 and discussed below.

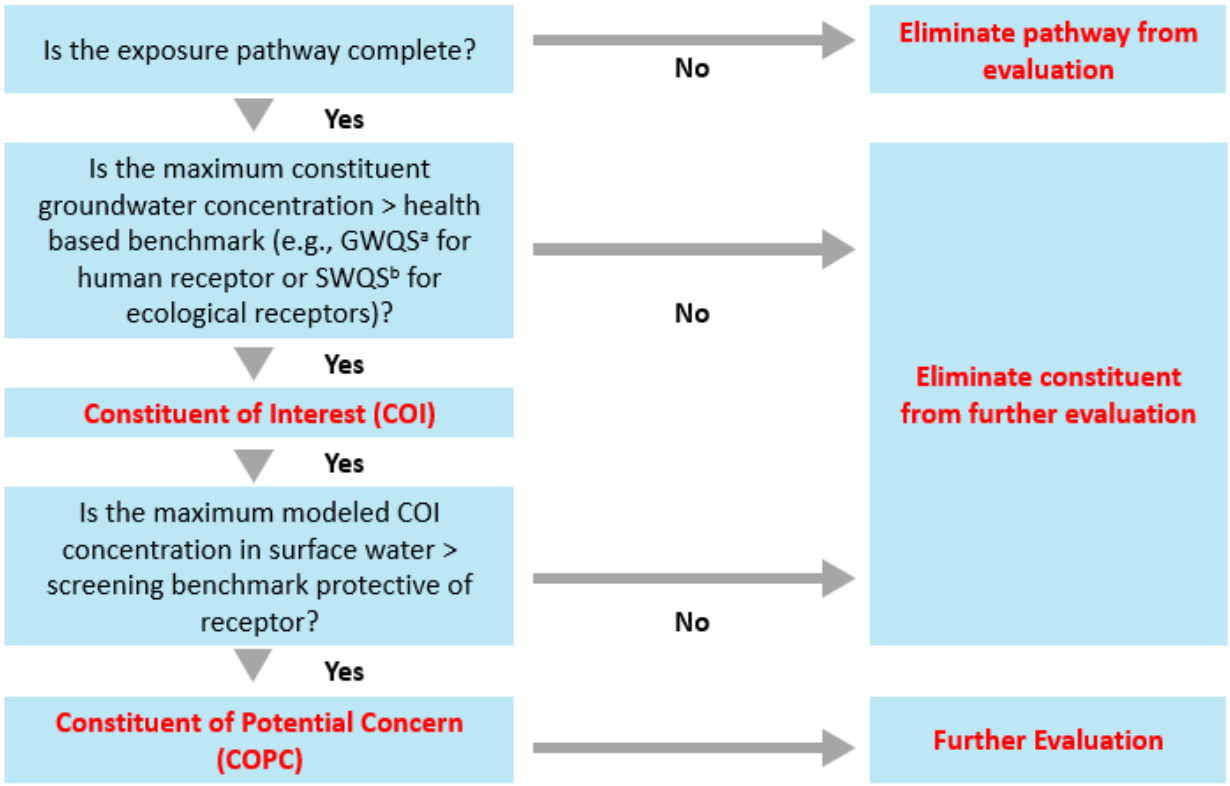

Figure 3.1 Overview of Risk Evaluation Methodology. Notes: IEPA = Illinois Environmental Protection Agency; GWQS = IEPA Groundwater Quality Standards; SWQS = IEPA Surface Water Quality Standards; US EPA = United States Environmental Protection Agency.
(a) The IEPA Part 845 groundwater protection standards were used to identify COIs.
(b) IEPA SWQS protective of chronic exposures to aquatic organisms were used to identify ecological COIs. In the absence of an SWQS, US EPA Region IV ecological screening values were used.

The first step in the risk evaluation was to develop the CEMs and identify complete exposure pathways. All potential receptors and exposure pathways based on groundwater use and surface water use in the

vicinity of the Site were considered. Exposure pathways that are incomplete were excluded from the evaluation.

Groundwater data were used to identify COIs. COIs were identified as constituents with maximum concentrations in groundwater in excess of groundwater quality standards (GWQS)[2] for human receptors and surface water quality standards (SWQS) for ecological receptors. Based on the CSM (Section 2.2), groundwater underlying the WAPS flows from south to north toward the Illinois River. Therefore, any potential WAPS-related constituents in groundwater would flow toward and into surface water.

Surface water samples have been collected from the Illinois River adjacent to the Site; however, sediment samples have not been collected from the river. Gradient modeled the potential migration of COIs from groundwater to surface water and sediment to evaluate potential risks to receptors (see Section 3.3.3). Gradient modeled the COI concentrations in surface water and sediment based on the groundwater data from the WAPS-related groundwater monitoring wells. The measured and modeled COI concentrations in surface water and the modeled sediment concentrations were compared to conservative, generic risk-based screening benchmarks for human health and ecological receptors. These generic screening benchmarks rely on default assumptions with limited consideration of site-specific characteristics. Human health benchmarks are receptor-specific values calculated for each pathway and environmental medium that are designed to be protective of human health. Ecological benchmarks are medium-specific values designed to be protective of all potential ecological receptors exposed to surface water. Ecological and human health screening benchmarks are inherently conservative because they are intended to screen out chemicals that are of no concern with a high level of confidence. Therefore, a measured or modeled COI concentration exceeding a screening benchmark does not indicate an unacceptable risk, but only that further risk evaluation is warranted. COIs with maximum concentrations exceeding a conservative screening benchmark are identified as COPCs requiring further evaluation.

As described in more detail below, this evaluation relied on the screening assessment to demonstrate that constituents present in groundwater underlying the WAPS do not pose an unacceptable human health or ecological risk. That is, after the screening step, no COPCs were identified and further assessment was not warranted.

3.2 Human and Ecological Conceptual Exposure Models

A CEM provides an overview of the receptors and exposure pathways requiring risk evaluation. The CEM describes the source of the contamination, the mechanism that may lead to a release of contamination, the environmental media to which a receptor may be exposed, the route of exposure (exposure pathway), and the types of receptors that may be exposed to these environmental media.

3.2.1 Human Conceptual Exposure Model

The human CEM for the Site depicts the relationships between the off-Site environmental media potentially impacted by constituents in groundwater and human receptors that could be exposed to these media. Figure 3.2 presents a human CEM for the Site. It considers a human receptor who could be exposed to COIs hypothetically released from the WAPS into groundwater, surface water, sediment, and fish. The following human receptors and exposure pathways were evaluated for inclusion in the Site-specific CEM.

[2] As discussed further in Section 3.3.2, GWQS are protective of human health and not necessarily of ecological receptors. While ecological receptors are not exposed to groundwater, groundwater can potentially enter into the adjacent surface water and impact ecological receptors. Therefore, two sets of COIs were identified: one for humans and another for ecological receptors.

- Residents – exposure to groundwater/surface water as drinking water;
- Residents – exposure to groundwater/surface water used for irrigation;
- Recreators in the river near the Site:
  - Boaters – exposure to surface water and sediment while boating;
  - Swimmers – exposure to surface water and sediment while swimming;
  - Anglers – exposure to surface water and sediment and consumption of locally caught fish.

All of these exposure pathways were considered complete except for residential exposure to groundwater or surface water used for drinking water or irrigation. Section 3.2.1.1 explains why the residential drinking water and irrigation pathways are incomplete, and Section 3.2.1.2 provides additional description of the recreational exposures.

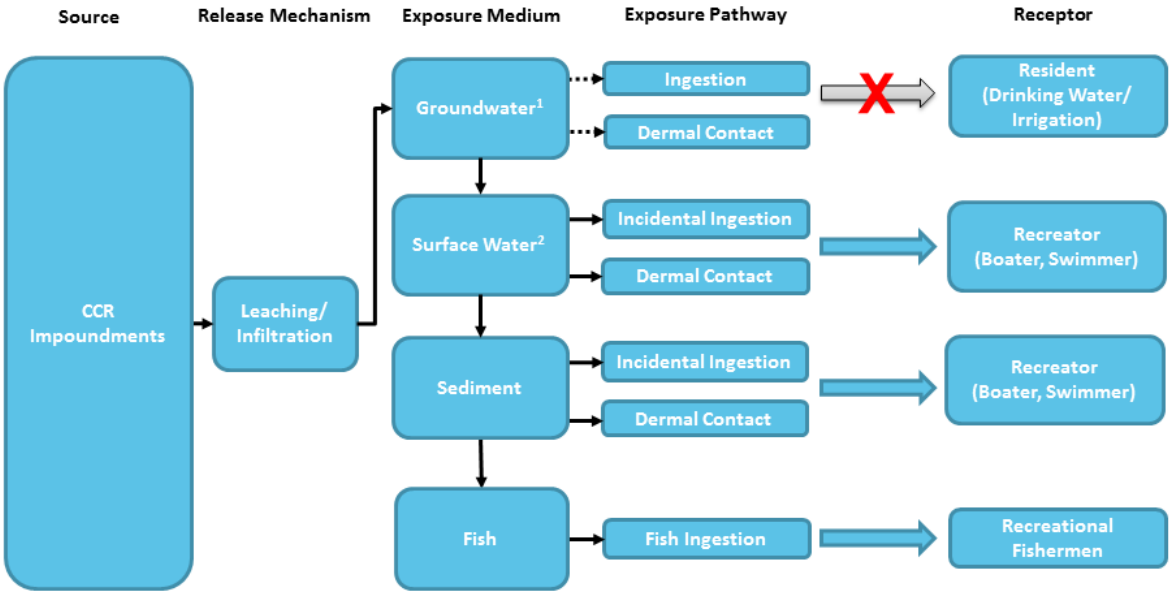

Figure 3.2 Human Conceptual Exposure Model. Notes: CCR = Coal Combustion Residual. Dashed line/Red X indicates incomplete or insignificant exposure pathway.
(1) Groundwater in the vicinity of the Site is not used as a drinking water or irrigation source.
(2) Surface water is not used as a drinking water source.

3.2.1.1 Groundwater or Surface Water as a Drinking Water/Irrigation Source

Groundwater as a source of drinking water and/or irrigation water is not a complete exposure pathway for CCR-related constituents originating from the WAPS. Specifically, shallow groundwater from the UAU in the vicinity of the WAPS is not used as a source of drinking water, and no public groundwater systems are downgradient of the site. Further, the downward migration of groundwater from the UAU is restricted due to the presence of a thick shale bedrock (NRT, 2017). A summary of the evidence supporting the conclusion that there are no residential uses of the shallow groundwater and Illinois River surface water as a source of drinking water is presented below:

- **No potential groundwater receptors are in the vicinity of the WAPS**. The public water systems (PWS) in the Putnam and Bureau Counties in the vicinity of the Hennepin WAPS rely on groundwater as a source of potable water. A review of existing drinking water intakes within the US EPA Safe Drinking Water Information System (SDWIS) (US EPA, 2024), IEPA Illinois Drinking Water Watch (IEPA, 2024a), and IEPA Map Server (IEPA, 2024b) databases yielded no PWS wells within 1,000 meters of the Site, as described below.
    - A total of 10 wells were identified within a 1,000-meter radius of the WAPS during a comprehensive search of the Illinois State Geological Survey (ISGS) Illinois Water and Related Wells (ILWATER) Map (ISGS, 2024b) (Figure 3.3). Under normal groundwater flow conditions, 2 out of the 10 wells are located downgradient from the WAPS (Well IDs 121552089500, and 121552089600), and the remaining 8 wells are located upgradient and/or side-gradient (Well IDs 121550009400, 121550009500, 121550012800, 121552043500, 121552059800, 121552059900, 121552070200, and 121552091200).
    - All 10 wells located within a 1,000-meter radius of the WAPS are listed as being owned by either "Power Plant", Illinois Power Company, Hennepin Power Station, or Dynegy Midwest-Hennepin Power (ISGS, 2024b). The wells include three monitoring wells; one irrigation well,[3] one industrial well, four wells with non-specific use, and one non-community public water well (ISGS, 2024b). The non-community public water well (121552043500) was installed in 1993 and is 120 feet deep; it is screened in sand and gravel from 90 to 115 feet bgs. However, this well is side-gradient to the WAPS (Figure 3.3).
    - A 2009 water well survey conducted in the area by Kelron/Natural Resource Technology concluded that CCR-impacted groundwater at the HPP is not likely to impact any existing potable or non-potable off-Site water wells that are located within 2,500 ft of the property boundary (Ramboll, 2018-2020; NRT, 2017).
    - In a letter to IEPA (Morris, 2021), DMG noted that 16 private wells were identified near the Site, with 1 well located potentially downgradient of the Site. However, DMG noted that this well is unlikely to be in use, based on the installation date (1884) and its remote floodplain location. DMG noted that three non-community water supply wells (CWS) were identified but that they are unlikely to be at risk because they are either inactive and/or not-located hydraulically downgradient of the WAPS.
- **There is no off-Site migration of WAPS-related constituents to nearby wells because all shallow groundwater flows into the Illinois River**. The Illinois River is the regional discharge point for groundwater in the UAU. Groundwater in the UAU flows to north/northwest into the Illinois River under normal conditions (OBG, 2019). Because the Illinois River is a large regional hydraulic boundary (*i.e.*, serves as a sink for groundwater discharges in the area), any potential constituents present in groundwater underlying the WAPS are not likely to migrate under or beyond the river.
- **The Illinois River adjacent to the Site is not used as a public water supply.** IEPA classified the Illinois River as a "General Use Water." IEPA fully supports the use of the Illinois River for aquatic life and primary contact recreation, but it is not designated for public and food processing water supplies. The segment of the Illinois River adjacent to the Site (Section D-16) is listed on the 2018 Illinois Section 303(d) List as being impaired for fish consumption, due to mercury and polychlorinated biphenyls (IEPA, 2016, IEPA, 2018 , IEPA, 2019b). Therefore, surface water adjacent to the Site is not used as a source of drinking water, and this exposure pathway was not evaluated further.

[3] The irrigation well is "used exclusively for irrigation of the coal pile." (NRT, 2017).

- **The WAPS has a limited hydraulic connection to underlying bedrock groundwater resources**. The bedrock aquitard is composed of a 300-400 ft thick shale unit of the Carbondale Formation (NRT, 2017). This thick, continuous shale bedrock forms a hydraulic barrier between the WAPS and deeper groundwater resources. Very low hydraulic conductivities of the shale bedrock and the lack of a downward gradient restrict any downward migration of shallow groundwater originating from the WAPS to the underlying aquifers (NRT, 2017).

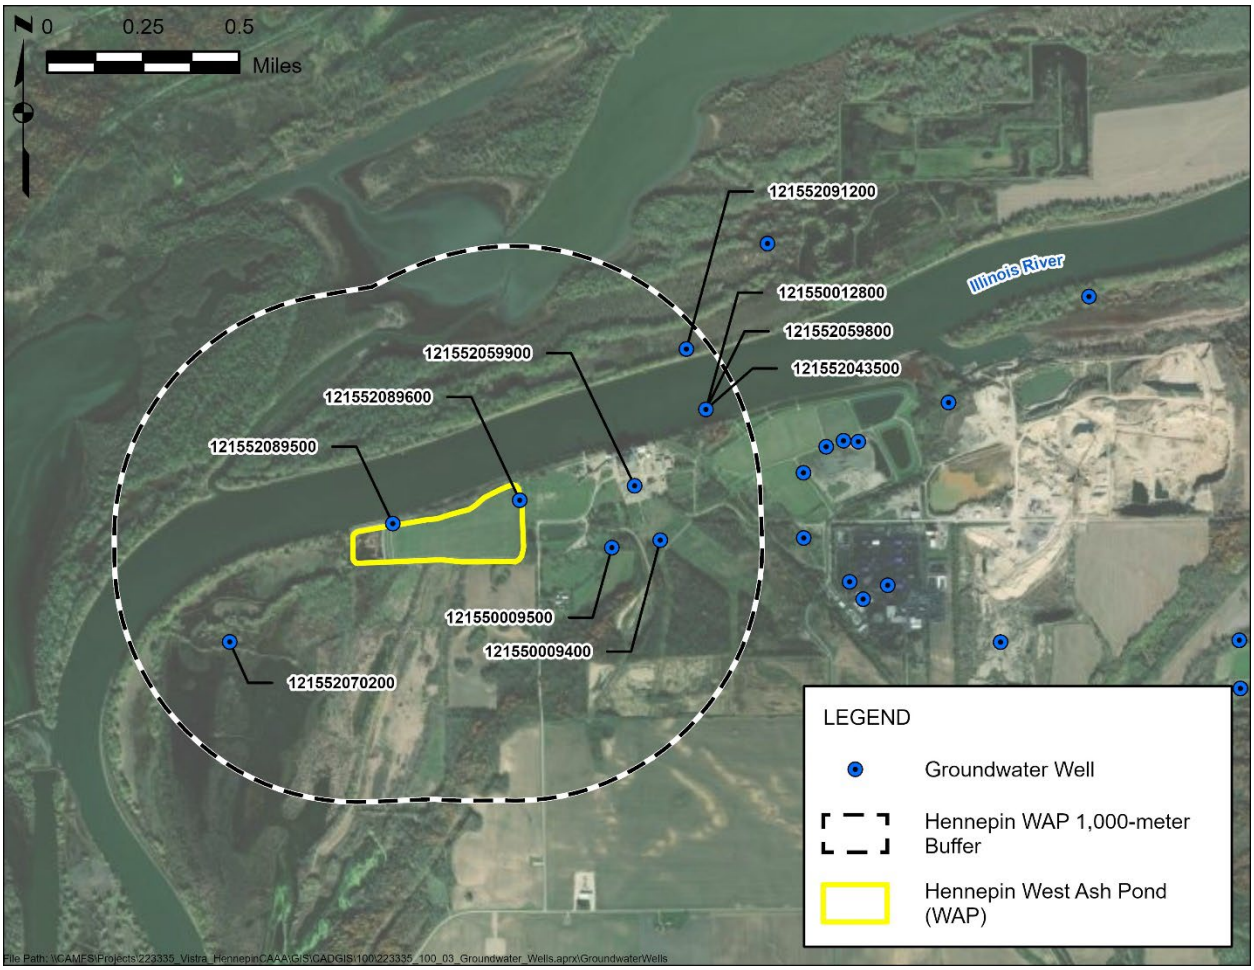

Figure 3.3 Water Wells Within 1,000 Meters of the West Ash Pond. Sources: Google LLC, 2024; ISGS, 2024b.

3.2.1.2 Recreational Exposures

The Illinois River flows east to west past the Site. Recreational exposure to surface water and sediment may occur during activities such as swimming or boating in the river. Exposure estimates for swimmers provide a health-protective means to evaluate exposure during other recreational activities. Recreational anglers may also consume locally caught fish from the Illinois River.

3.2.2 Ecological Conceptual Exposure Model

The ecological CEM for the Site depicts the relationships between off-Site environmental media (surface water and sediment) potentially impacted by COIs in groundwater and ecological receptors that may be

exposed to these media. The ecological risk evaluation considered both direct toxicity as well as secondary toxicity *via* bioaccumulation. Figure 3.4 presents the ecological CEM for the Site. The following ecological receptor groups and exposure pathways were considered:

- **Ecological Receptors Exposed to Surface Water:**
  - Aquatic plants, amphibians, reptiles, and fish.
- **Ecological Receptors Exposed to Sediment:**
  - Benthic invertebrates (*e.g.*, insects, crayfish, mussels).
- **Ecological Receptors Exposed to Bioaccumulative COIs:**
  - Higher trophic-level wildlife (avian and mammalian) *via* direct exposures (surface water and sediment exposure) and secondary exposures through the consumption of prey (*e.g.*, plants, invertebrates, small mammals, fish).

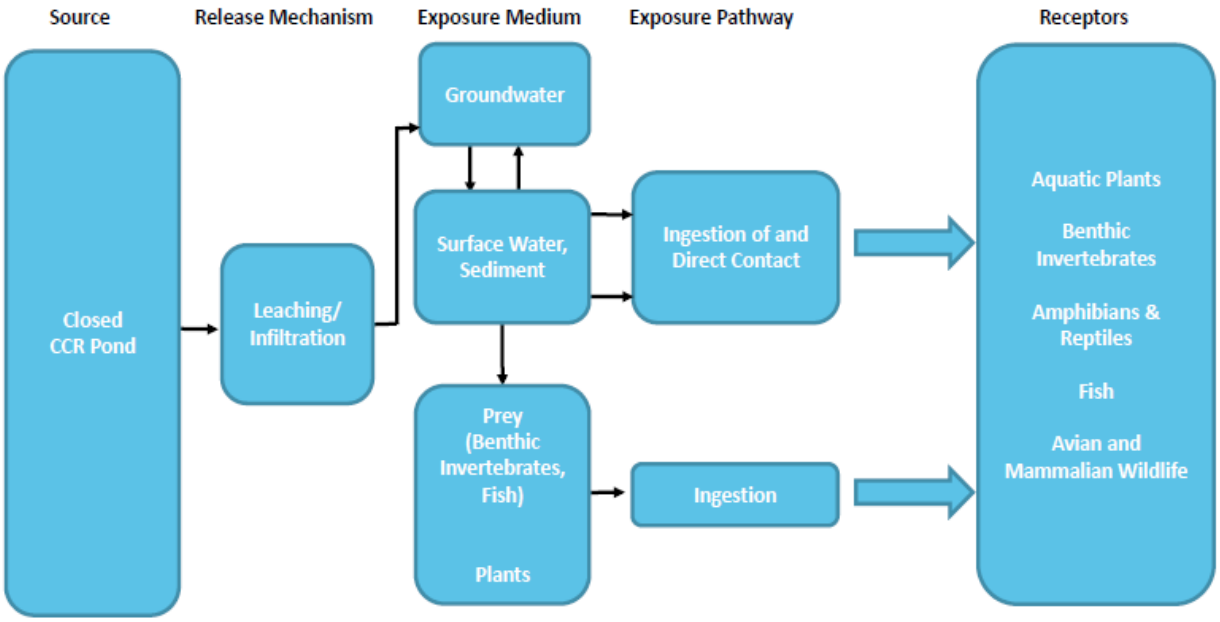

Figure 3.4 Ecological Conceptual Exposure Model. Notes: CCR = Coal Combustion Residual.

3.3 Identification of Constituents of Interest

Risks were evaluated for COIs. A constituent was considered a COI if the maximum detected constituent concentration in groundwater exceeded a health-based benchmark. According to US EPA risk assessment guidance (US EPA, 1989), this screening step is designed to reduce the number of constituents carried through the risk evaluation that are anticipated to have a minimal contribution to the overall risk. Identified COIs are the constituents that are most likely to pose a risk concern in the surface water adjacent to the Site.

3.3.1 Human Health Constituents of Interest

For the human health risk evaluation, COIs were conservatively identified as constituents with maximum concentrations in groundwater above the GWPSs listed in the Illinois CCR Rule Part 845.600 (IEPA, 2021). The use of groundwater data in this risk evaluation does not imply that detected constituents are associated

with the WAPS or that they have been identified as potential groundwater exceedances. Using this approach, the COIs identified for the human health risk evaluation *via* a surface water pathway include arsenic, boron, cadmium, cobalt, iron, lithium, manganese, molybdenum, and thallium (Table 3.1).

The water quality parameters that exceeded the GWPS included sulfate and total dissolved solids (TDS); however, these constituents were not included in the risk evaluation because the GWPS are likely based on aesthetic quality. US EPA set secondary maximum contaminant levels (MCLs) for sulfate and TDS based on aesthetic quality. The sulfate (250 mg/L) MCL is based on salty taste. The secondary MCL for TDS (500 mg/L) is based on hardness, colored water, staining, and salty taste (US EPA, 2021). Given that these parameters are not likely to pose a human health risk concern in the event of exposure, they were not identified as COIs.

Table 3.1 Human Health Constituents of Interest

Analyte[a]	Maximum Groundwater Concentration[b]	GWPS[c]	Human Health COI[d]

Notes:
COI = Constituent of Interest; GWPS = Groundwater Protection Standard; ND = Not Detected; SU = Standard Units
Shaded cell indicates a compound identified as a COI.
(a) The constituents are those listed in the IL Part 845.600 GWPS (IEPA, 2021).
(b) The maximum detected groundwater concentration was used to identify COIs.
(c) The IL Part 845.600 GWPS (IEPA, 2021) were used to identify COIs.
(d) COIs are constituents for which the maximum concentration exceeds the groundwater standard.
(e) Sulfate and TDS exceed the GWPS but are not considered to be COIs because the GWPS are likely based on aesthetic quality (see text above).

3.3.2 Ecological Constituents of Interest

The Illinois GWPS, as defined in IEPA's guidance, were developed to protect human health but not necessarily ecological receptors. While ecological receptors are not exposed to groundwater, groundwater can potentially migrate into the adjacent surface water and impact ecological receptors. Therefore, to identify ecological COIs, the maximum concentrations of analytes detected in groundwater were compared to ecological surface water benchmarks protective of aquatic life.

The surface water screening benchmarks for freshwater organisms were obtained from the following hierarchy of sources:

- IEPA (2019a) SWQS. IEPA SWQS are health-protective benchmarks for aquatic life exposed to surface water on a long-term basis (*i.e.*, chronic exposure). The SWQS for several metals are hardness dependent (cadmium, chromium, copper, fluoride, lead, manganese, nickel, and zinc). Screening benchmarks for these constituents were calculated assuming US EPA's (2019a) default hardness of 100 mg/L.[4]
- US EPA Region IV (2018) surface water Ecological Screening Values (ESVs) for hazardous waste sites.

For radium, benchmarks from the United States Department of Energy's (US DOE) guidance document, "A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota" (US DOE, 2019), were used. US DOE presents benchmarks for radium-226 and radium-228 separately (4 and 3 pCi/L, respectively). Given that radium concentrations are expressed as total radium (radium-226+228, *i.e.*, the

[4] While hardness data are not available for the Illinois River adjacent to the Site, a US Geological Survey station (05556200) located at Hennepin, Illinois, approximately five miles downstream from the Site, measured hardness concentrations ranging from 200 to 370 mg/L, with a mean hardness of 288 mg/L, from 106 samples collected between 1980 and 1997 (USGS, 2021b). These are older data and may not reflect current conditions; therefore, US EPA's default hardness of 100 mg/L was used. However, use of a higher hardness value (288 mg/L) would result in less stringent screening values, and thus, use of the US EPA default hardness is conservative.

sum of radium-226 and radium-228), Gradient used the lower of the two benchmarks (3 pCi/L for radium-228) to evaluate total radium concentrations.

Consistent with the human health risk evaluation, Gradient used the maximum detected concentrations from groundwater samples collected from the WAPS-associated wells without considering spatial or temporal representativeness for ecological receptor exposures. The use of the maximum constituent concentrations in this evaluation is designed to conservatively identify COIs that warrant further investigation. Boron, cadmium, and iron were identified as COIs for ecological receptors (Table 3.2).

It should be noted that although cadmium and cobalt were screened in as ecological COIs based on the maximum groundwater concentration, neither constituent was detected in surface water (out of 17 samples) (Table 2.3). In addition, no constituent was detected in surface water at a concentration exceeding its ecological benchmark (Table 3.3). The maximum detection limit (0.001 mg/L) for cadmium and cobalt was just slightly above the ecological benchmark for cadmium, but below the ecological benchmark for cobalt (Table 3.3). A total of 158 groundwater samples were analyzed for radium-226+228; of these, only two samples had radium slightly above the ecological benchmark of 3 pCi/L (3.09 and 3.06 pCi/L). Based on a Rosner test for outliers (run in ProUCL 5.1), both samples were considered outliers at the 1% significance level. Thus, radium-226+228 was not considered an ecological COI.

3.3.3 Surface Water and Sediment Modeling

Surface water sampling has been conducted in the Illinois River adjacent to the Site. To estimate the potential contribution to surface water (and sediment) from groundwater specifically associated with the WAPS, Gradient modeled concentrations in the Illinois River surface water and sediment from groundwater discharge to the Illinois River for the detected COIs. This is because the constituents detected in groundwater above a health-based benchmark are most likely to pose a risk concern in the adjacent surface water. Gradient modeled human health and ecological COI concentrations in the surface water and sediment using a mass balance calculation based on the surface water and groundwater mixing. The model assumes a well-mixed groundwater-surface water location.

The maximum detected concentrations in groundwater (regardless of well location) from 2018 to 2023 were conservatively used to model COI concentrations in surface water and sediment. For COIs that were measured as both total and dissolved fractions, we used the maximum of the total and dissolved COI concentrations for the modeling. In this case, the maximum concentration was from the total fraction for all COIs. Use of the total metal concentration for these COIs may overestimate surface water concentrations because dissolved concentrations, which are lower than total concentrations, represent the mobile fractions of constituents that could likely flow into and mix with surface water.

The modeling approach does not account for geochemical transformations that may occur during groundwater mixing with surface water. Gradient assumed that predicted surface water concentrations were influenced only by the physical mixing of groundwater as it enters the surface water and were not further influenced by the geochemical reactions in the water and sediment, such as precipitation. In addition, the model only predicts surface water and sediment concentrations as a result of the potential migration of COI concentrations in WAPS-related groundwater and does not account for background concentrations in surface water or sediment.

For this evaluation we adapted a simplified and conservative form of US EPA's indirect exposure assessment methodology (US EPA, 1998) that was used in US EPA's coal combustion waste risk assessment (US EPA, 2014). The original model is a mass balance calculation based on surface water and groundwater mixing and the concept that the dissolved and sorbed concentrations can be related through an equilibrium partitioning coefficient (K_d). The model assumes a well-mixed groundwater-surface water location, with partitioning among total suspended solids, dissolved water column, sediment porewater, and solid sediments.

Sorption to soil and sediment is highly dependent on the surrounding geochemical conditions. To be conservative, we ignored the natural attenuation capacity of soil and sediment and estimated the surface water concentration based only on the physical mixing of groundwater and surface water (*i.e.*, dilution) at the point of discharge of groundwater to the surface water.

The aquifer and surface water properties used to estimate the volume of groundwater flowing into the Illinois River and surface water concentrations are presented in Table 3.4. The COI concentrations in sediment were modeled using the COI-specific sediment-to-water partition coefficients and the sediment properties presented in Table 3.5. In the absence of Site-specific information for the Illinois River, we used default assumptions (*e.g.*, depth of the upper benthic layer and bed sediment porosity) to model sediment concentrations. The modeled surface water and sediment concentrations are presented in Table 3.6. These modeled concentrations reflect conservative contributions from groundwater flowing into the Illinois River. A description of the modeling and the detailed results are presented in Appendix A.

Table 3.4 Groundwater and Surface Water Properties Used in Modeling

Parameter	Unit	Values	Notes/Source
Groundwater			
COI Concentration	mg/L	Constituent-specific	Maximum detected concentration in groundwater
Cross Sectional Area for the UAU	m^2	11,613	Average thickness of the UAU (*i.e.*, 50 ft, or 15.2 m) multiplied by the length of WAPS adjacent to the Illinois River (2500 ft, or 762 m) (NRT, 2017)
Hydraulic Gradient	m/m	0.005	Horizontal hydraulic gradient from WAPS to off-site areas during normal river stage (NRT, 2017)
Hydraulic Conductivity of the UAU	cm/s	0.017	Geometric mean horizontal hydraulic conductivity measured for wells finished in gravel only (NRT, 2017)
Surface Water			
Surface Water Flow Rate	L/yr	4.56×10^{12}	Representative low flow (10^{th} percentile) discharge rate for the Illinois River (5,100 cfs), as derived from USGS station at Henry (USGS 05558300) (USGS, 2021a)
Total Suspended Solids (TSS)	mg/L	40	Median TSS measured in Illinois River at Hennepin (Tetra Tech, 2012)
Depth of the Water Column	m	4	Maximum "water depth at the 75% exceedance discharge condition" is 4-5 m (USGS, 2024)
Suspended Sediment to Water Partition Coefficient	mg/L	Constituent-specific	Values based on US EPA (2014)

Notes:
cfs = Cubic Feet per Second; COI = Constituent of Interest; US EPA = United States Environmental Protection Agency.

Table 3.5 Sediment Properties Used in Modeling

Parameter	Unit	Value	Notes/Source
Sediment			
Depth of Upper Benthic Layer	m	0.03	Default (US EPA, 2014)
Depth of Water Body	m	4.03	Depth of water column (4 m) plus depth of upper benthic layer (0.03 m) (US EPA, 2014)
Bed Sediment Particle Concentration	g/cm^3	1	Default (US EPA, 2014)
Bed Sediment Porosity	-	0.6	Default (US EPA, 2014)
TSS Mass per Unit Area	kg/m^2	0.16	Depth of water column × TSS × conversion factors (10^6 kg/mg and 1,000 L/m^3)
Sediment Mass per Unit Area	kg/m^2	30	Depth of upper benthic layer × bed sediment particulate concentration × conversion factors (0.001 kg/g, 10^6 cm^3/m^3)
Sediment to Water Partition Coefficients	mg/L	Constituent specific	Values based on US EPA (2014)

Notes:
TSS = Total Suspended Solids; US EPA = United States Environmental Protection Agency.

Table 3.6 Surface Water and Sediment Modeling Results

COI	Maximum Measured Groundwater Concentration (mg/L)	Mass Discharge Rate (mg/year)	Modeled Surface Water Concentration (mg/L)	Modeled Sediment Concentration (mg/kg)
Arsenic	3.8E-02	1.2E+07	2.6E-06	5.0E-04
Boron	1.8E+01	5.6E+09	1.2E-03	6.0E-03
Cadmium	9.6E-03	3.0E+06	6.6E-07	3.2E-04
Cobalt	9.9E-03	3.1E+06	6.8E-07	2.4E-04

Thallium	3.6E-03	1.1E+06	2.5E-07	3.3E-06

Notes:
COI = Constituent of Interest; NA = Not Applicable.
(a) Lithium sorbed to sediment was not calculated because lithium lacks a K_d value.

3.4 Human Health Risk Evaluation

The section below presents the results of the human health risk evaluation for recreators (swimmers and anglers) along the Illinois River adjacent to the Site. Risks were assessed using the maximum measured and modeled COIs in surface water.

3.4.1 Recreators Exposed to Surface Water

Screening Exposures: Recreators could be exposed to surface water *via* incidental ingestion and dermal contact while swimming. In addition, anglers could consume fish caught in the Illinois River. The maximum measured or modeled COI concentrations in surface water were used as conservative upper-end estimates of the COI concentrations to which a recreator might be exposed directly (incidental ingestion of COIs in surface water while swimming) and indirectly (consumption of locally caught fish exposed to COIs in surface water).

Screening Benchmarks: Illinois surface water criteria (IEPA, 2019a), known as human threshold criteria (HTC), are based on incidental exposure through contact or ingestion of small volumes of water while swimming or during other recreational activities, as well as the consumption of fish. The HTC values were calculated from the following equation (IEPA, 2019a):

$$\mathrm{HTC} = \frac{\mathrm{ADI}}{\mathrm{W} + (\mathrm{F} \times \mathrm{BCF})}$$

where:

HTC = Human health protection criterion in milligrams per liter (mg/L)
ADI = Acceptable daily intake (mg/day)
W = Water consumption rate (L/day)
F = Fish consumption rate (kg/day)
BCF = Bioconcentration factor (L/kg)

Illinois defines the acceptable daily intake (ADI) as the "maximum amount of a substance which, if ingested daily for a lifetime, results in no adverse effects to humans" (IEPA, 2019a). US EPA defines its chronic reference dose (RfD) as an "estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure for a chronic duration (up to a lifetime) to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime" (US EPA, 2011a). Illinois lists methods to derive an ADI from the primary literature (IEPA, 2019a). In accordance with Illinois guidance, we derived an ADI by multiplying the MCL by the default water ingestion rate of 2 L/day (IEPA, 2019a). In the absence of an MCL, we used the RfD used by US EPA to derive its Regional Screening Levels (RSLs) (US EPA, 2023) as a conservative estimate of the ADI. The RfDs are given in mg/kg-day, while the ADIs are given in mg/day; thus, we multiplied the RfD by a standard body weight of 70 kg to obtain the ADI in mg/day. The calculation of the HTC values is shown in Appendix Table B.1.

We used bioconcentration factors (BCFs) from a hierarchy of sources. The primary BCFs were those that US EPA used to calculate the national recommended water quality criteria (NRWQC) for human health (US EPA, 2002, 2016). Other sources included BCFs used in the US EPA coal combustion ash risk assessment (US EPA, 2014) and BCFs reported by Oak Ridge National Laboratory's Risk Assessment Information System (ORNL RAIS).[5] Lithium did not have a BCF value available from any authoritative source. Therefore, the water quality criterion for lithium was calculated assuming a BCF of 1. This is a conservative assumption as lithium does not readily bioaccumulate in the aquatic environment (ECHA, 2020a,b; ATSDR, 2010).

Illinois recommends a fish consumption rate of 0.020 kg/day (20 g/day) for an adult weighing 70 kg (IEPA, 2019a). Illinois recommends a water consumption rate of 0.01 L/day for "incidental exposure through contact or ingestion of small volumes of water while swimming or during other recreational activities" (IEPA, 2019a). Appendix Table B.1 presents the calculated HTC for fish and water, and for fish consumption only.

Screening Risk Evaluation: The maximum modeled and measured COI concentrations in surface water were compared to the calculated Illinois HTC values (Table 3.7). All surface water concentrations were below their respective benchmarks. The HTC values are protective of recreational exposure *via* water and/or fish ingestion and do not account for dermal exposures to COIs in surface water while swimming. However, given that the modeled COI surface water concentrations are orders of magnitude below HTC protective of water and/or fish ingestion, dermal exposures to COIs are not expected to be a risk concern. Moreover, the dermal uptake of metals is considered to be minimal and only a small proportion of ingestion exposures. Thus, none of the COIs evaluated would be expected to pose an unacceptable risk to recreators exposed to surface water while swimming and anglers consuming fish caught in the Illinois River.

[5] Although recommended by US EPA (2015c), US EPA EpiSuite 4.1 (US EPA, 2019b) was not used as a source of BCFs because inorganic compounds are outside the estimation domain of the program.

Table 3.7 Risk Evaluation for Recreators Exposed to Surface Water

COI	Maximum Surface Water Concentration (modeled) (mg/L)	Maximum Surface Water Concentration (measured) (mg/L)	HTC for Water and Fish (mg/L)	HTC for Water Only (mg/L)	HTC for Fish Only (mg/L)	COPC based on modeled	COPC based on measured
Arsenic	2.6E-06	1.2E-03	2.2E-02	2.0E+00	2.3E-02	No	No
Boron	1.2E-03	2.2E-01	4.7E+02	1.4E+03	7.0E+02	No	No
Cadmium	6.6E-07	ND	1.8E-03	1.0E+00	1.9E-03	No	No

Thallium	2.5E-07	ND	1.7E-03	4.0E-01	1.7E-03	No	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; HTC = Human Threshold Criteria; ND = Not Detected; SW = Surface Water; WAPS = West Ash Pond System.
(a) Measured surface water concentrations may be different from modeled concentrations because measured data include the effects of background and other industrial sources. Modeled concentrations only represent the potential effect on surface water quality resulting from the measured groundwater concentrations.

3.4.2 Recreators Exposed to Sediment

Recreational exposure to sediment may occur during boating and swimming activity along the Illinois River; exposure to sediment may occur through incidental ingestion and dermal contact.

Screening Exposures: COIs in impacted groundwater flowing into the river can sorb to sediments. In the absence of sediment data, sediment concentrations were modeled using maximum detected groundwater concentrations.

Screening Benchmarks: There are no established recreator RSLs that are protective of recreational exposures to sediment (US EPA, 2019c). Therefore, benchmarks that are protective of recreational exposures to sediment *via* incidental ingestion and dermal contact were calculated using US EPA's RSL guidance (US EPA, 2019c). These benchmarks were calculated using the recommended assumptions (*i.e.*, oral bioavailability, body weights, averaging time) and toxicity reference values (*i.e.*, RfD and cancer slope factor [CSF]), with the following changes: Recreators were assumed to be exposed to sediment while recreating 60 days a year (or 2 weekend days per week for 30 weeks a year, from April to October). The exposure duration was assumed for a child 6 years of age and an adult 20 years of age, per US EPA guidance (Stalcup, 2014). The daily recommended residential soil ingestion rates of 200 mg/day for a child and 100 mg/day for an adult are based on an all-day exposure to residential soils (Stalcup, 2014; US EPA, 2011b). Since recreational exposures to sediment are assumed to occur for less than 3 hours per day, one-third of the daily residential soil ingestion (67 mg/day for a child and 33 mg/day for an adult) was used as a conservative assumption.

For dermal exposures, recreators were assumed to be exposed to sediment on their lower legs and feet (1,026 cm^2 for the child and 3,026 cm^2 for the adult, based on the age-weighted surface areas reported in US EPA, 2011b). While other body parts may be exposed to sediment, the contact time will likely be very short, as the sediment would wash off in the surface water. We used US EPA's recommended adherence factor of 0.2 mg/cm^2 based on child exposure to wet soil (US EPA, 2004; Stalcup, 2014), which was used in the US EPA RSL User's Guide for a child recreator exposed to soil or sediment (US EPA, 2019c). The

sediment screening benchmarks for cadmium and cobalt were calculated based on a target hazard quotient of 1. Appendix Table B.2 presents the calculation of RSLs protective of recreational exposures to sediment.

Screening Risk Evaluation: The modeled sediment concentrations were well below the recreational sediment RSLs (Table 3.8). Therefore, exposure to sediment is not expected to pose an unacceptable risk to recreators while swimming or boating.

Table 3.8 Risk Evaluation for Recreators Exposed to Sediment

COI	Modeled Sediment Concentration (mg/kg)	Recreator RSL (mg/kg)	COPC
Arsenic	5.0E-04	6.8E+01	No
Boron	6.0E-03	2.7E+05	No
Cadmium	3.2E-04	1.2E+02	No
Cobalt	2.4E-04	4.1E+02	No
Iron	1.9E-02	9.6E+05	No
Lithium	NA[a]	2.7E+03	No
Manganese	1.2E+00	3.3E+04	No
Molybdenum	2.2E-03	6.8E+03	No
Thallium	3.3E-06	1.4E+01	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; NA = Not Available; RSL = Regional Screening Level.
(a) Lithium could not be modeled in sediment because it lacks a K_d value.

3.5 Ecological Risk Evaluation

Based on the ecological CEM (Figure 3.4), ecological receptors could be exposed to surface water and dietary items (*i.e.*, prey and plants) potentially impacted by identified COIs (cadmium and cobalt).

3.5.1 Ecological Receptors Exposed to Surface Water

Screening Exposures: The ecological evaluation considered aquatic communities in the Illinois River potentially impacted by identified ecological COIs. Measured and modeled surface water concentrations were compared to risk-based ecological screening benchmarks.

Screening Benchmarks: Surface water screening benchmarks protective of aquatic life were obtained from the following hierarchy of sources:

- IEPA SWQS (IEPA, 2019a), regulatory standards that are intended to protect aquatic life exposed to surface water on a long-term basis (*i.e.*, chronic exposure). For cadmium, the surface water benchmark is hardness dependent and calculated using a default hardness of 100 mg/L[6];
- NRWQC – Aquatic Life Criteria Table (US EPA, 2019a); and
- US EPA Region IV (2018) surface water ESVs for hazardous waste sites.

[6] While USGS hardness data are available, US EPA's (2019a) default hardness of 100 mg/L was conservatively used. Conservatisms associated with using a default hardness value are discussed in Section 3.4.

Risk Evaluation: The maximum modeled COI concentrations in surface water were compared to the benchmarks protective of aquatic life (Table 3.9). The measured and modeled surface water concentrations were below their respective benchmarks. Thus, none of the COIs evaluated are expected to pose an unacceptable risk to aquatic life in the Illinois River.

Table 3.9 Risk Evaluation of Ecological Receptors Exposed to Surface Water

COI	Maximum Surface Water Concentration, Modeled (mg/L)	Maximum Detected SW Conc (mg/L)	Ecological Freshwater Benchmark (mg/L)	Basis	COPC Based on Modeled Values	COPC Based on Measured Values
Boron	1.2E-03	2.2E-01	7.6E+00	IEPA (2019a)	No	No
Cadmium	6.6E-07	ND	1.1E-03	IEPA (2019a)	No	No
Iron	7.6E-04	2.4E-01	1.0E+00	US EPA Region IV (2018)	No	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; IEPA = Illinois Environmental Protection Agency; N = No; ND = Not Detected; SW = Surface Water; US EPA R4 = United States Environmental Protection Agency Region IV.
(a) Modeled COI concentrations reflect the potential maximum COI surface water concentrations from groundwater mixing with surface water.
(b) A default hardness value of 100 mg/L was used to calculate this hardness-dependent benchmark.

3.5.2 Ecological Receptors Exposed to Sediment

Screening Exposures: COIs in impacted groundwater discharging into the Illinois River can sorb to sediments *via* chemical partitioning. In the absence of sediment data, sediment concentrations were modeled using maximum detected groundwater concentrations. Therefore, the modeled COI sediment concentrations reflect the potential maximum Site-related sediment concentration from groundwater discharge.

Screening Benchmarks: Sediment screening benchmarks were obtained from US EPA Region IV (2018). The majority of the sediment ESVs are based on threshold effect concentrations (TECs) from MacDonald *et al.* (2000), which provide consensus values that identify concentrations below which harmful effects on sediment-dwelling organisms are unlikely to be observed. The benchmarks used in this evaluation are listed in Table 3.10.

Screening Risk Results: The maximum modeled COI sediment concentrations were below their respective sediment screening benchmarks (Table 3.10). The modeled sediment concentrations attributed to potential contributions from Site groundwater for all COIs were less than 1% of the sediment screening benchmark. Therefore, the modeled sediment concentrations attributed to potential contributions from Site groundwater are not expected to significantly contribute to ecological exposures in the Illinois River adjacent to the Site.

Table 3.10 Risk Evaluation of Ecological Receptors Exposed to Sediment

COI	Modeled Sediment Concentration (mg/kg)	ESV[a] (mg/kg)	COPC	% of Benchmark
Boron	5.97E-03	38[c]	No	0.02%
Cadmium	3.16E-04	0.99	No	0.03%
Iron	1.90E-02	20,000	No	0.0001%

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; ESV = Ecological Screening Value; NOEC = No Observed Effect Concentration; US EPA = United States Environmental Protection Agency.
(a) ESV from US EPA Region IV (2018).
(c) Boron NOEC of 38 mg/kg was used as a conservative benchmark for boron in the absence of an ESV (ECHA, 2019 219-6670).

3.5.3 Ecological Receptors Exposed to Bioaccumulative Constituents of Interest

Screening Exposures: COIs with bioaccumulative properties can impact higher-trophic-level wildlife exposed to these COIs *via* direct exposures (surface water and sediment exposure) and secondary exposures through the consumption of dietary items (*e.g.*, plants, invertebrates, small mammals, and fish).

Screening Benchmark: US EPA Region IV (2018) guidance and IEPA's SWQS (IEPA, 2019a) guidance were used to identify analytes with potential bioaccumulative effects.

Risk Evaluation: The ecological COIs (boron, cadmium and iron)[7] were not identified as having potential bioaccumulative effects. Therefore, these COIs are not considered to pose an ecological risk *via* bioaccumulation.

3.6 Uncertainties and Conservatisms

A number of uncertainties and their potential impact on the risk evaluation are discussed below. Wherever possible, conservative assumptions were used in an effort to minimize uncertainties and overestimate rather than underestimate risks.

Exposure Estimates:

- The risk evaluation included the IL Part 845.600 constituents detected in groundwater samples collected from wells downgradient of the WAPS. However, it is possible that not all of the detected constituents are related specifically to the WAPS, since there are several sources in this area.
- The human health and ecological risk characterizations were based on the maximum modeled COI concentrations, rather than on averages. Thus, the variability in exposure concentrations was not considered. Given that receptors are mobile and concentrations change over time, assuming continuous exposure to the maximum concentration overestimates human and ecological exposures. For example, US EPA guidance states that risks should be estimated using average exposure concentrations as represented by the 95% upper confidence limit on the mean (US EPA, 1992). Given that exposure estimates based on the maximum concentrations did not exceed risk benchmarks, we have greater confidence that there is no risk concern.

[7] US EPA Region IV (2018) identifies only mercury (including methyl mercury) and selenium as having potential bioaccumulative effects. IEPA (2019a) identifies mercury as the only metal with bioaccumulative properties. Mercury and selenium were detected in groundwater but were not considered ecological COIs.

- Only analytes detected in groundwater were used to identify COIs and model COI concentrations in surface water and sediment. For the constituents that were not detected in WAPS groundwater, the detection limits were below the IL Part 845 GWPS and thus do not require further evaluation.
- COI concentrations in surface water were modeled using the maximum detected total or dissolved COI concentrations. In this case, maximum detected concentrations for cadmium, cobalt, and lithium are based on total concentrations. Modeling surface water concentrations using total metal concentrations for these COIs may overestimate surface water concentrations because dissolved concentrations, which are lower than total concentrations, represent the mobile fractions of constituents that could likely flow into and mix with surface water.
- The COIs identified in this evaluation also occur naturally in the environment. Contributions to exposure from natural or other non-WAPS-related sources were not considered in the evaluation of modeled concentrations; only exposure contributions potentially attributable to Site groundwater mixing with surface water were evaluated. While not quantified, exposures from potential WAPS-related groundwater contributions are likely to represent only a small fraction of the overall human and ecological exposure to COIs that also have natural or non-WAPS-related sources.
- Screening benchmarks for human health were developed using exposure inputs based on US EPA's recommended values for reasonable maximum exposure (RME) assessments (Stalcup, 2014). RME is defined as "the highest exposure that is reasonably expected to occur at a site but that is still within the range of possible exposures" (US EPA, 2004). US EPA states the "intent of the RME is to estimate a conservative exposure case (*i.e.*, well above the average case) that is still within the range of possible exposures" (US EPA, 1989). US EPA also notes that this high-end exposure "is the highest dose estimated to be experienced by some individuals, commonly stated as approximately equal to the 90th percentile exposure category for individuals" (US EPA, 2015b). Thus, most individuals will have lower exposures than those presented in this risk assessment.
- Although the maximum radium-226+228 concentration in groundwater exceeded the ecological screening benchmark, radium-226+228 was not considered an ecological COI because the two highest results, detected slightly above the benchmark, were considered outliers at the 1% significance level. While risks to ecological receptors exposed to radium-226+228 in surface water, sediment, and diet were not evaluated, the risks are expected to be *de minimis*.[8]

Toxicity Benchmarks:

- Screening-level ecological benchmarks were compiled from IEPA and US EPA guidance and designed to be protective of the majority of Site conditions, leaving the option for Site-specific refinement. In some cases, these benchmarks may not be representative of the Site-specific conditions or receptors found at the Site, or may not accurately reflect concentration-response relationships encountered at the Site. For example, the ecological benchmark for cadmium is hardness dependent. While a US Geological Survey [USGS] station had available hardness data, we relied on US EPA's default hardness of 100 mg/L due to the limitations of the USGS data. USGS data from Hennepin, Illinois (five miles downstream of the Site) reported hardness ranging from 200 to 370 mg/L, with a mean hardness of 288 mg/L, based on samples collected in 1980-
