[8] Radium was not analyzed in surface water. However, the surface water and sediment modeling for other ecological COIs demonstrate that the modeled concentrations are orders of magnitude lower than the measured COI concentration in surface water and sediment. Given that the maximum groundwater concentration slightly exceeds the surface water benchmark, the modeled surface water and sediment concentrations will be below their respective benchmarks. Furthermore, radium is not described in US EPA Region IV guidance, but it is identified as bioaccumulative by other entities (*e.g.*, ATSDR, 1990). However, the benchmark used to identify ecological COIs already considers bioaccumulative exposures. Given that the modeled concentrations are anticipated to be below benchmarks, which account for bioaccumulative exposures, radium-226+228 is not expected to pose a risk concern to ecological receptors based on its bioaccumulative properties.

1997 (USGS, 2021b). Increasing the hardness from 100 to 288 mg/L would increase the cadmium SWQS because benchmarks become less stringent with higher levels of hardness. Regardless of the hardness, the maximum modeled cadmium concentration is orders of magnitude below the SWQS.

- In addition, for the ecological evaluation, we conservatively assumed all constituents to be 100% bioavailable. Modeled COI concentrations in surface water are considered total COI concentrations. US EPA recommends using dissolved metals as a measure of exposure to ecological receptors because it represents the bioavailable fraction of metal in water (US EPA, 1993). Therefore, the modeled surface water COI concentrations may be an overestimation of exposure concentrations to ecological receptors.
- In general, it is important to appreciate that the human health toxicity factors used in this risk evaluation are developed to account for uncertainties, such that safe exposure levels used as benchmarks are often many times lower (even orders of magnitude lower) than the levels that cause effects that have been observed in human or animal studies. For example, toxicity factors incorporate a 10-fold safety factor to protect sensitive subpopulations. This means that a risk exceedance does not necessarily equate to actual harm.

4 Summary and Conclusions

A screening-level risk evaluation was performed for Site-related constituents in groundwater at the Hennepin Power Plant in Hennepin, Illinois. The CSM developed for the Site indicates that groundwater beneath the WAPS flows into the Illinois River adjacent to the Site and may potentially impact surface water and sediment.

CEMs were developed for human and ecological receptors. The complete exposure pathways for humans include recreators in the Illinois River who are exposed to surface water and sediment (boaters and swimmers) and anglers who consume locally caught fish. Based on the local hydrogeology, residential exposure to groundwater used for drinking water or irrigation is not a complete pathway and was not evaluated. The complete exposure pathways for ecological receptors include aquatic life (including aquatic and marsh plants, amphibians, reptiles, and fish) exposed to surface water; benthic invertebrates exposed to sediment; and avian and mammalian wildlife exposed to bioaccumulative COIs in surface water, sediment, and dietary items.

Surface water data collected in 2020 and 2021, and groundwater data collected from 2018 to 2023, were used to estimate exposures. The maximum detected concentrations in surface water were used for human and ecological receptors exposed to surface water. For analytes detected in groundwater, surface water concentrations were also modeled using the maximum detected groundwater concentration. In the absence of sediment data, modeled sediment concentrations based on the maximum detected groundwater concentrations were used as the exposure estimate for human and ecological receptors. Surface water and sediment exposure estimates were screened against benchmarks protective of human health and ecological receptors for this risk evaluation.

For recreators (boaters and swimmers) exposed to surface water, all COIs were below the conservative risk-based screening benchmarks. Therefore, none of the COIs evaluated in surface water are expected to pose an unacceptable risk to recreators swimming or boating in the Illinois River adjacent to the Site.

For recreators exposed to sediment *via* incidental ingestion and dermal contact, the modeled sediment concentrations for all COIs were below the health protective sediment benchmarks. Therefore, the modeled concentrations in sediment are not expected to pose an unacceptable risk to recreators exposed to sediment in the Illinois River adjacent to the Site.

For anglers consuming locally caught fish, the maximum measured and modeled concentrations of all COIs in surface water were below conservative benchmarks protective of fish consumption. Therefore, none of the COIs evaluated are expected to pose an unacceptable risk to recreators consuming fish caught in the Illinois River.

Ecological receptors exposed to surface water include aquatic and marsh plants, amphibians, reptiles, and fish. The risk evaluation showed that none of the modeled or measured COIs in surface water exceeded protective screening benchmarks. Ecological receptors exposed to sediment include benthic invertebrates. The modeled sediment COIs did not exceed the conservative screening benchmarks; therefore, none of the COIs evaluated in sediment are expected to pose an unacceptable risk to ecological receptors. Ecological receptors were also evaluated for exposure to bioaccumulative COIs. This evaluation considered higher-trophic-level wildlife with direct exposure to surface water and sediment and secondary exposure through the consumption of dietary items (*e.g.*, plants, invertebrates, small mammals, fish). The ecological COIs

were not identified as having potential bioaccumulative effects. Therefore, these COIs are not considered to pose an ecological risk *via* bioaccumulation. Overall, this evaluation demonstrated that none of the COIs evaluated are expected to pose an unacceptable risk to ecological receptors.

It should be noted that this evaluation incorporates a number of conservative assumptions that tend to overestimate exposure and risk. The risk evaluation was based on the maximum detected COI concentration; however, US EPA guidance states that risks should be based on a representative average concentration such as the 95% upper confidence limit on the mean; thus, using the maximum concentration tends to overestimate exposure. Although the COIs identified in this evaluation also occur naturally in the environment, the contributions to exposure from natural background sources and nearby industry were not considered; thus, CCR-related exposures were likely overestimated. Exposure estimates assumed 100% metal bioavailability, which likely results in overestimates of exposure and risks. Exposure estimates were based on inputs to evaluate the RME; thus, most individuals will have lower exposures than those estimated in this risk assessment.

Finally, it should be noted that because current conditions do not present a risk to human health or the environment, there will also be no unacceptable risk to human health or the environment for future conditions when the WAPS is closed. For all future closure scenarios, potential releases of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline.

Appendix A

Surface Water and Sediment Modeling

Gradient modeled concentrations in river surface water and sediment based on available groundwater data. First, we estimated the flow rate of constituents of interest (COIs) flowing to the Illinois River *via* groundwater. Then, we adapted United States Environmental Protection Agency's (US EPA's) indirect exposure assessment methodology (US EPA, 1998) in order to model surface water and sediment water concentrations in the Illinois River.

Model Overview

The groundwater flow into the river is represented by a one-dimensional steady-state model. In this model, the groundwater plume migrates horizontally in the uppermost aquifer, from south to north, in the direction of the Illinois River. The groundwater flow entering the river is the flow going through a cross-sectional area that has a length equal to the length of the river adjacent to the West Ash Pond System (WAPS) with potential coal combustion residual (CCR)-related impacts and a height equal to the saturated thickness of the uppermost aquifer (Table 3.4). It was assumed that all the groundwater flowing through the uppermost aquifer flows into the Illinois River. The length of the river adjacent to the WAPS was estimated using Google Earth Pro.

The groundwater flow into the river mixes with the surface water in the Illinois River. The COIs entering the river *via* groundwater can dissolve into the water column, sorb to suspended sediments, or sorb to benthic sediments. Using US EPA's indirect exposure assessment methodology (US EPA, 1998), the model evaluates the surface water and sediment concentrations at a location downstream of the groundwater discharge, assuming a well-mixed water column.

Groundwater Discharge Rate

We used conservative assumptions to evaluate the groundwater discharge rate of the COIs. We conservatively assumed that the groundwater concentrations were uniformly equal to the maximum detected concentration for each individual COI. We ignored adsorption by subsurface soil and assumed that all the groundwater flowing through the uppermost aquifer flows into the river.

For each groundwater unit, the groundwater flow rate into the river was derived using Darcy's Law:

$$Q = KiA$$

where:

Q = Groundwater flow rate (m^3/s)
K = Hydraulic conductivity (m/s)
i = Hydraulic gradient (m/m)
A = Cross-sectional area (m^2)

For each COI, the mass discharge rate into the river was then calculated by:

$$m_c = C_c \times Q \times CF$$

where:

m_c = Mass discharge rate of the COI (mg/year)
C_c = Maximum groundwater concentration of the COI (mg/L)
CF = Conversion factors needed for unit conversion: 1,000 L/m^3; 31,557,600 s/year

The values of the aquifer parameters used for these calculations are provided in Table A.1. The calculated mass discharge rates were then used as inputs for the surface water and sediment partitioning model.

Surface Water and Sediment Concentration

Groundwater flowing into the river gets diluted in the surface water flow. Constituents transported by groundwater into the surface water migrate into the water column and the bed sediments. The surface water model we used to estimate the surface water and sediment concentrations is a steady-state model described in US EPA's indirect exposure assessment methodology (US EPA, 1998) and also used in US EPA's "Human and Ecological Risk Assessment of Coal Combustion Residuals" (US EPA, 2014). This model describes the partitioning of constituents between surface water, suspended sediments, and benthic sediments based on equilibrium partition coefficients. It estimates the concentrations of constituents in surface water, suspended sediments, and benthic sediments at steady-state equilibrium at a theoretical location downstream of the discharge point after complete mixing of the water column. In our analysis, we used the partitioning coefficients given in Table J-1 of the US EPA CCR Risk Assessment for all COIs (US EPA, 2014). These coefficients are presented in Table A.2.

To be conservative, we assumed that the constituents were not affected by dissipation or degradation once they entered the water body. The total water body concentration of the COI was calculated as (US EPA, 1998):

$$C_{wtot} = \frac{m_c}{V_f \times f_{water}}$$

where:

C_{wtot} = Total water body concentration of the constituent (mg/L)
V_f = Water body annual flow (L/year)
f_{water} = Fraction of COI in the water column (unitless)
m_c = Mass discharge rate of the COI (mg/year)

For the Illinois River annual flow rate, we conservatively used the low flow (10th percentile) discharge rate of about 5,100 cubic feet per second (cfs) based on the daily mean discharge rates measured at Henry (USGS station #05558300)[9] between 1981 and 2021 (USGS, 2021).

The fraction of COIs in the water column was calculated for each COI using the sediment/water and suspended solids/water partition coefficients (US EPA, 2014). The fraction of COIs in the water column is defined as (US EPA, 2014):

$$f_{water} = \frac{(1 + [K_{dsw} \times TSS \times 0.000001]) \times \frac{d_w}{d_z}}{\left([1 + (K_{dsw} \times TSS \times 0.000001)] \times \frac{d_w}{d_z}\right) + ([bsp + K_{dbs} \times bsc] \times \frac{d_b}{d_z})}$$

where:

K_{dsw} = Suspended sediment-water partition coefficient (mL/g)
K_{dbs} = Sediment-water partition coefficient (mL/g)

[9] The USGS station at Henry, located approximately 18 miles downstream of the Hennepin plant, is the closest USGS gauging station with surface water flow data.

TSS	=	Total suspended solids in the surface water body (mg/L), set equal to the median river concentration of 40 mg/L (TetraTech, 2012)
0.000001	=	Units conversion factor
d_w	=	Depth of the water column (m)
d_b	=	Depth of the upper benthic layer (m), set equal to 0.03 m (US EPA, 2014)
$d_z = d_w + d_b$	=	Depth of the water body (m)
bsp	=	Bed sediment porosity (unitless), set equal to 0.6 (US EPA, 2014)
bsc	=	Bed sediment particle concentration (g/cm^3), set equal to 1.0 g/cm^3 (US EPA, 2014)

The fraction of COIs dissolved in the water column (f_d) is calculated as (US EPA 2014):

$$f_d = \frac{1}{1 + K_{dsw} \times TSS \times 0.000001}$$

The values of the fraction of COIs in the water column and other calculated parameters are presented in Table A.3. Other water body parameters are presented in Table A.4.

The total water column concentration (C_{wcTot}) of the COIs, comprising both the dissolved and suspended sediment phases, is then calculated as (US EPA, 2014):

$$C_{wcTot} = C_{wtot} \times f_{water} \times \frac{d_z}{d_w}$$

Finally, the dissolved water column concentration (C_{dw}) for the COIs is calculated as (US EPA, 2014):

$$C_{dw} = f_d \times C_{wcTot}$$

The dissolved water column concentration was then used to calculate the concentration of COIs sorbed to suspended solids in the water column (US EPA, 1998):

$$C_{sw} = C_{dw} \times K_{dsw}$$

where:

C_{sw}	=	Concentration sorbed to suspended solids (mg/kg)
C_{dw}	=	Concentration dissolved in the water column (mg/L)
K_{dsw}	=	Suspended solids/water partition coefficient (mL/g)

In the same way, using the total water body concentration and the fraction of COIs in the benthic sediments, the model derives the total concentration in benthic sediments (US EPA, 2014):

$$C_{bstot} = f_{benth} \times C_{wtot} \times \frac{d_z}{d_b}$$

where:

C_{bstot}	=	Total concentration in bed sediment (mg/L or g/m^3)

C_{wtot} = Total water body concentration of the constituent (mg/L)
f_{benth} = Fraction of contaminant in benthic sediments (unitless)
d_b = Depth of the upper benthic layer (m)
$d_z = d_w + d_b$ = Depth of the water body (m)

This value can be used to calculate dry weight sediment concentration as follows:

$$C_{sed-dw} = \frac{C_{bstot}}{bsc}$$

where:

C_{sed-dw} = Dry weight sediment concentration (mg/kg)
C_{bstot} = Total sediment concentration (mg/L)
bsc = Bed sediment bulk density (used the default value of 1 g/cm^3 from US EPA, 2014)

The total sediment concentration is composed of the concentration dissolved in the bed sediment pore water (equal to the concentration dissolved in the water column) and the concentration sorbed to benthic sediments (US EPA, 1998).

The concentration sorbed to benthic sediments was calculated from (US EPA, 1998):

$$C_{sb} = C_{dbs} \times K_{dbs}$$

where:

C_{sb} = Concentration sorbed to bottom sediments (mg/kg)
C_{dbs} = Concentration dissolved in the sediment pore water (mg/L)
K_{dbs} = Sediments/water partition coefficient (mL/kg)

For each COI, the modeled total water column concentration, the modeled dry weight sediment concentration, and the modeled concentration sorbed to sediment are presented in Table A.5.

Table A.1 Parameters Used to Estimate Groundwater Discharge to Surface Water

GW Unit	Parameter	Full Name	Value	Unit
Uppermost Aquifer	A	Cross-Sectional Area	11,613	m^2
Uppermost Aquifer	i	Hydraulic Gradient	0.005	m/m
Uppermost Aquifer	K	Hydraulic Conductivity	0.017	cm/s

Notes:
GW = Groundwater, UA = Uppermost Aquifer.
Average thickness of the UA (*i.e.*, 50 ft or 15.2 m) multiplied by the length of the WAP-intersecting Illinois River (2,500 ft, or 762 m).
Source: NRT (2017).

Table A.2 Partition Coefficients

Constituent	Sediment-Water, Mean, K_{dbs}		Suspended Sediment-Water, Mean, K_{dsw}	
	Value (log_{10}) (mL/g)	Value (mL/g)	Value (log_{10}) (mL/g)	Value (mL/g)
Arsenic (III)	2.4	2.51E+02	3.9	7.94E+03
Boron	0.8	6.31E+00	3.9	7.94E+03
Cadmium	3.3	2.00E+03	4.9	7.94E+04
Cobalt	3.1	1.26E+03	4.8	6.31E+04
Iron	1.4	2.51E+01	1.4	2.51E+01
Lithium	Not Available	Not Available	Not Available	Not Available
Manganese	4.4	2.80E+04	4.4	2.80E+04
Molybdenum	2.5	3.16E+02	4.4	2.51E+04
Thallium	1.3	2.00E+01	4.1	1.26E+04

Notes:
Lithium was not modeled because it lacks a K_d value in US EPA (2014).
Source: US EPA (2014).

Table A.3 Calculated Parameters

Constituent	Fraction of Constituent in the Water Column f_{water}	Fraction of Constituent in the Benthic Sediments $f_{benthic}$	Fraction of Constituent Dissolved in the Water Column $f_{dissolved}$
Arsenic (III)	0.4110	0.5890	0.7589
Boron	0.9622	0.0378	0.7589
Cadmium	0.2182	0.7818	0.2394
Cobalt	0.2717	0.7283	0.2838

Notes:

ADI = Average Daily Intake; BCF = Bioconcentration Factor; F = Fish Consumption Rate; HTC = Human Threshold Criteria; IEPA = Illinois Environmental Protection Agency; MCL = Maximum Contaminant Level; NA = BCF Not Available and Therefore, WQC for Fish Only Not Calculated; NC = No Criterion Available; NRWQC = National Recommended Water Quality Criteria; ORNL RAIS = Oak Ridge National Laboratory Risk Assessment Information System; RfD = Reference Dose; W = Water Consumption Rate; WQC = Water Quality Criteria; SWQC = Surface Water Quality Criteria; US EPA = United States Environmental Protection Agency.

(a) BCFs from the following hierarchy of sources:

NRWQC (US EPA, 2016). National Recommended Water Quality Criteria.

NRWQC (US EPA, 2002). National Recommended Water Quality Criteria: 2002. Human Health Criteria Calculation Matrix.

US EPA (2014). Human and Ecological Risk Assessment of Coal Combustion Residuals.

ORNL RAIS (ORNL, 2023). Risk Assessment Information System (RAIS) Chemical Toxicity Values.

(b) ADI based on the MCL is calculated as the MCL (mg/L) multiplied by a water ingestion rate of 2 L/day. In the absence of an MCL, the ADI was calculated as the RfD (mg/kg-d) multiplied by the body weight (70 kg).

(c) SWQC based on US EPA's action level.

(d) BCF of 1 was used as a conservative assumption, due to lack of published BCF.

Equations from IEPA (2019a):

Consumption of Water and Fish

$$HTC = \frac{ADI}{W + (F \times BCF)}$$

Incidental Consumption of Water only

$$HTC = \frac{ADI}{W}$$

Consumption of Fish only

$$HTC = \frac{ADI}{F \times BCF}$$

Where

Average Daily Intake (ADI)	=	Chem. Specific	mg/day
Fish Consumption Rate (F)	=	0.02	kg/day
Bioconcentration Factor (BCF)	=	Chem. Specific	L/kg-tissue
Water Consumption Rate (W)	=	0.01	L/day

1. INTRODUCTION AND BACKGROUND

1.1 Plant and Site Information

Dynegy Midwest Generation, LLC (DMG) is the owner of the inactive coal-fired Hennepin Power Plant (HPP), also referred to as the Hennepin Power Station (HEN), in Hennepin, Putnam County, Illinois. DMG intends to complete groundwater corrective action at the coal combustion residuals (CCR) surface impoundment (SI) West Ash Pond System (WAPS), which is identified by Illinois Environmental Protection Agency (IEPA) identification (ID) numbers (No.) W1550100002-01 and W1550100002-03, CCR Unit ID 804, and National Inventory of Dams Number IL50698. The WAPS is comprised of the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). WAPS was constructed as a single unit with a single perimeter dike and subsequently internally divided into the OWAP and OWPP as part of operational practices. Source control (*e.g.*, closure) was completed in 2020; this included leaving CCR in place within the OWAP, removing all CCR from the OWPP, placing it within the OWAP, and installing a geomembrane final cover system over the consolidated OWAP [1, 2]. This document and all past engineering and hydrogeological studies consider the WAPS as a single CCR unit. Groundwater corrective action for the HEN WAPS will be performed under the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments [3] and the requirements of Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257, herein referred to as the Federal CCR Rule [4].

1.2 CAAA-SIR Background and Scope

35 I.A.C. § 845 requires a Corrective Action Alternatives Analysis (CAAA) to be completed as part of remedy selection, pursuant to the requirements of 35 I.A.C. § 845.670(e). The CAAA for the HEN WAPS will be prepared by Gradient Corporation (Gradient). Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Corrective Action Alternatives Analysis Supporting Information Report (CAAA-SIR) to provide information requested by Gradient to support the CAAA for the HEN WAPS.

This CAAA-SIR is a feasibility-level assessment utilized to evaluate multiple groundwater corrective action alternatives. The remedy that is selected within the CAAA, to which this CAAA-SIR is attached, is then further developed into a permit-level remedy within the Corrective Action Plan (CAP), to which the CAAA is attached. Therefore, there may be minor differences in information presented for the selected remedy between this CAAA-SIR and the CAP. Information that may be different includes, but is not limited to, groundwater quality data, groundwater modeling inputs and results, implementation schedules, time to reach GWPSs, physical dimensions and scope of the remedy, and engineering design parameters. These differences are due to the further remedy refinement that is inherent with advancing the selected alternative into the permit-level remedy that is included within the CAP.

1.2.1 Identified Corrective Action Alternatives

Corrective action remedies selected for evaluation within this CAAA-SIR include:

- Alternative 1: Source control with groundwater polishing (GWP); and
- Alternative 2: Source control with continuous containment system.

Multiple remedies were evaluated in the Corrective Measures Assessment (CMA), prepared by Ramboll and attached to the CAAA prepared by Gradient, including source control with GWP, source control with cutoff wall, source control with *in-situ* stabilization (ISS), source control with permeable reactive barrier (PRB), source control with in-situ chemical treatment, and source control with groundwater extraction.

Out of these remedies, source control with GWP, source control with cutoff wall, and source control with ISS were identified for further assessment, while the remaining remedies were determined to be infeasible. As part of further assessment performed during this CAAA-SIR modeling and development, the following adjustments were made to the remedies identified by the CMA:

- Following groundwater modeling, the source control with ISS remedy was determined to be infeasible and omitted for inclusion in this CAAA-SIR, for the reasons described below:
  - ISS would require the temporary removal of approximately 15 acres of the 30-acre completed WAPS final cover system. Removal of the final cover system could allow for significant stormwater infiltration into CCR within the WAPS, potentially leading to temporary reductions in the effectiveness of the completed source control.
  - ISS would require handling of tens of thousands of cubic yards of CCR and CCR-impacted ISS cuttings on the surface of the WAPS. These activities could lead to an elevated risk of releasing CCR-impacted stormwater and sediments during construction activities, which could result in negative impacts to adjacent environmentally sensitive areas.
- The source control with cutoff wall remedy was expanded into the source control with continuous containment system remedy. The remedy includes a deep cutoff wall that is integrated with the existing cover system to provide lateral and surface isolation of the CCR from the surrounding environment and keyed into the competent shale bedrock which will provide isolation below the WAPS. Additional information on the expanded remedy is provided in Section 3.

1.2.2 Scope of CAAA-SIR

Ramboll completed the following tasks and documented the tasks within this CAAA-SIR, for each of the corrective action alternative remedies listed in **Section 1.2.1**:

- Feasibility-level design drawings (**Appendix A**) were developed to show the approximate extents and typical details of the Alternative 2 remedy (source control with continuous containment system). Drawings were not prepared for the Alternative 1 remedy as it does not involve construction at the site.
- Narratives describing the implementation of each remedy were developed, including the pre-design, design, construction, and closeout phases.
- Feasibility-level schedules providing the estimated time to implement the remedy were developed, including design, permitting, and construction.
- Information required to evaluate specific portions of 35 I.A.C. § 845.670(e) requirements were prepared, as requested by Gradient, including 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3).

- Estimates of implementation-based equipment mileage, vehicle delivery mileage, labor hour, and labor commuting mileage, were developed for each remedy alternative where physical construction activities are expected to occur.

All remedies presented in this CAAA-SIR are in conjunction with source control for the WAPS, which was completed in 2020 ("2020 closure") in accordance with the closure plan and supporting groundwater modeling that was submitted to and approved by IEPA in 2018 [5, 6, 1, 2]. Source control was the primary corrective action completed for the WAPS and utilized a consolidate-and-cap approach. The consolidate-and-cap approach included excavating all CCR from the OWPP portion of the WAPS, constructing a sheet pile wall and compacted clay buttress to separate the closure-by-removal and closure-in-place (CIP) portions of the WAPS, placing the CCR excavated from the OWPP in the OWAP portion of the WAPS, and then capping the CIP area with a geosynthetic and soil final cover system ("completed WAPS final closure"). The design of the source control was supported by groundwater modeling included in the IEPA-approved 2017 closure plan (**Appendix B2**).

1.2.3 Criterion for Estimating Time to Achieve GWPS

Times to achieve GWPS for each of the remedial alternative remedies were estimated for the wells within the existing WAPS compliance monitoring system, using updated groundwater modeling that incorporated the 2020 closure, as provided in **Appendix B1**. This approach was utilized to provide a consistent comparison of the estimated time to reach GWPS for each remedy, as required by 35 I.A.C. § 845.670(e)(f).

Closure for the WAPS serves as the primary corrective action for the unit and was completed in 2020, as discussed in **Section 1.2.2**. Supplemental remedial alternatives for the WAPS will need to be integrated with the completed closure. This affects the time to reach GWPS for each remedy, as the timeframe for each remedial alternative to become functional varies based on the required level of remedy permitting, design, and construction, or lack thereof. To provide a simplified comparative framework for the remedial alternatives, the groundwater modeling provided in **Appendix B1** assumed that Corrective Action Plans would be approved in 2026 and that construction for the source control with continuous containment system remedy would be completed in 2028.

1.3 Report Contents

The following information is included within this report:

- **Section 1** includes the introduction and background;
- **Section 2** includes information for the Alternative 1 remedy: source control with GWP;
- **Section 3** includes information for the Alternative 2 remedy: source control with continuous containment system;
- **Section 4** includes a brief summary of times to reach GWPS for Alternatives 1 through 3;
- **Section 5** includes information used to develop estimates of material quantities, labor hours, and mileage; and
- **Section 6** includes reference documents used in the development of this CAAA-SIR.

2. ALTERNATIVE 1 REMEDY: SOURCE CONTROL WITH GROUNDWATER POLISHING

The Alternative 1 remedy, source control with GWP, includes the already completed consolidate-and-cap approach for source control, after which GWP would be implemented via a formalized process. GWP is a remedial alternative that relies on natural geochemical processes and may be appropriate as recognized by the United States Environmental Protection Agency (USEPA) in a final policy directive for groundwater remediation [7]. GWP has been naturally occurring at the WAPS since source control was completed in 2020. For the purposes of this CAAA-SIR, the Alternative 1 remedy would involve formalizing the ongoing natural GWP processes as the corrective action remedy for the WAPS.

2.1 Supporting Groundwater Modeling and Time to Reach GWPS

The COCs exceeding[1] the GWPS at compliance groundwater monitoring wells as of the 2024 Annual Report [8] include arsenic, boron, lithium, sulfate, and TDS. Boron was selected for modeling the source control presented in the Final Closure Plan and was identified as a surrogate for other exceedances of the GWPS (**Appendix B2**). For modeling purposes, it was assumed that boron would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]) which is a conservative estimate for predicting contaminant transport times in the model. Boron transport is likely to be affected by both chemical and physical attenuation mechanisms (*i.e.,* adsorption and/or precipitation reactions as well as dilution and dispersion). Physical attenuation (dilution and dispersion) of contaminants in groundwater is simulated in the groundwater computer models. Chemical attenuation mechanisms and their effect on modeled times for exceedances to reach the GWPS are discussed in the Groundwater Polishing Evaluation Report [9] which is attached to the CAAA and discussed herein.

Groundwater modeling was performed to support the closure plan for the WAPS in 2017 (**Appendix B2**). This groundwater modeling identified that removing CCR from the OWPP portions of the WAPS was necessary to reduce times to reach GWPS. This was incorporated into the closure plan, and closure in accordance with the IEPA-approved closure plan was implemented in 2020 [1, 2]. More than three years of post-closure groundwater monitoring has subsequently been collected. The calibration associated with the 2017 groundwater model was updated to include that data as part of this CAAA-SIR, as discussed in the Groundwater Modeling Technical Memorandum included in **Appendix B1** [10]. The updated groundwater model estimated, for an assumed start of remedial action in 2026, that GWPS would be met for all wells in the monitoring system in 2055. This is 29 years after the assumed start of corrective action for all wells and 6 years on average (mean) for wells in the current monitoring system.

2.2 Remedy Implementation

Implementation of the source control portion of this remedy was completed in 2020 [1, 2]. Although a formal GWP remedy has not yet been initiated and approved by IEPA, GWP processes

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of DMG's operating permit application for the HPP WAPS. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, DMG has not identified any actual exceedances.

have been ongoing since the closure was completed. Implementation of GWP would include formalizing the GWP remedy. This would include performing corrective action groundwater monitoring, enacting an adaptive management strategy, and, after GWPS have been met, performing corrective action closure and completion activities. Information associated with each of these activities is described below.

- Corrective Action Groundwater Monitoring
  - Regular corrective action groundwater monitoring would be conducted utilizing a corrective action groundwater monitoring system designed in accordance with 35 I.A.C. § 845.680(c), which specifies that wells must be installed in the plume of contamination that lies beyond the waste boundary.
    - Samples would be collected for major ions for evaluating groundwater chemistry and COCs. Samples would be collected on a quarterly basis initially and potentially reduced to a semiannual basis once five years of monitoring have occurred, in accordance with 35 I.A.C. § 845.650(b)(4).
    - Monitoring results would be submitted to IEPA for each monitoring event, in addition to an annual groundwater monitoring and corrective action report, in accordance with 35 I.A.C. § 845.610(e).
    - Routine maintenance of the monitoring well system would occur during the monitoring period. This would include inspecting the wells, making repairs to the wells (as and if needed), and rehabilitating and/or replacing wells to improve performance (as and if needed).
- Adaptive Management during Monitoring
  - Groundwater monitoring results would be evaluated and documented in the monitoring reports submitted to IEPA, in accordance with 35 I.A.C. § 845.610(e).
  - If remedy progress does not correspond with expectations, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. § 845.680(b).
- Corrective Action Confirmation Monitoring and Completion
  - After GWPS have been met for all corrective action monitoring wells, corrective action confirmation groundwater monitoring would be implemented. This would include monitoring each well for three additional years to confirm that GWPS have been achieved, in accordance 35 I.A.C. § 845.680(c).
    - It should be noted that this could occur prior to or after completion of the 30-year post-closure care groundwater monitoring requirement associated with 35 I.A.C. § 845.780(c).
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification would be prepared and submitted to IEPA, in accordance with 35 I.A.C. § 845.680(e).

2.2.1 Remedy Implementation Schedule

A feasibility-level implementation schedule for the Alternative 1 source control with GWP remedy is provided in **Table A** below.

Table A. Feasibility-Level Implementation Schedule – Alternative 1 Source Control with GWP

Implementation Phase	Implementation Task	Timeframe (Preliminary Estimates)
Corrective Action Monitoring and Closeout	Corrective Action Monitoring (Time to Meet GWPS)	348 months (29 years)
	Corrective Action Groundwater Confirmation Monitoring	36 months
	Corrective Action Completion	6 months
	Timeframe to Complete Corrective Action Implementation	390 months
Total Timeline to Complete Corrective Action (after approval of Corrective Action Plan)		390 months (33 years)

2.2.2 Management of Extracted Groundwater

No groundwater extraction would occur under this remedy.

2.2.3 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) Information

As requested by Gradient, the following information required by 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) has been developed for the remedy. The information was developed based on preliminary-level information contained within the CMA for the HEN WAPS and then refined based on additional feasibility-level design activities performed as part of the development of this CAAA-SIR.

- Potential Need for Replacement of the Remedy – 35 I.A.C. § 845.670(e)(1)(H)
  - No replacement of the remedy would be required for source control with GWP, as a physical remedy would not be constructed.
- Degree of Difficulty Associated with Constructing the Remedy – 35 I.A.C. § 845.670(e)(3)(A)
  - No construction would be required with the source control with GWP remedy; therefore, there is no difficulty in constructing the remedy.
- Expected Operational Reliability of the Remedy - 35 I.A.C. § 845.670(e)(3)(B)
  - A report detailing the GWP process [9] has been developed and evaluates the reliability and the potential for reversibility of the chemical attenuation mechanisms. This report is attached to the Gradient CAAA.
- Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies - 35 I.A.C. § 845.670(e)(3)(C)
  - No permits are needed outside of approval of the eventual CAP.

- Availability of Necessary Equipment and Specialists - 35 I.A.C. § 845.670(e)(3)(D)
  - Equipment and specialists for field data collection and groundwater sampling are required for the GWP alternative. Laboratory equipment and specialists would also be required to assess groundwater concentrations of site constituents. Groundwater professionals (*i.e.*, geologists, hydrogeologists, statisticians, geochemists) would be required to perform statistical analysis and other assessments to confirm that GWP is functioning as intended and prepare corrective action-related groundwater monitoring and progress reports.
  - The equipment and specialists required for site groundwater monitoring and analysis are currently performing this work as part of the routine groundwater monitoring program in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring for this alternative.
- Available Capacity and Location of Needed Treatment, Storage, and Disposal Services – 35 I.A.C. § 845.670(e)(3)(E)
  - No treatment, storage, or disposal services would be required with the source control with GWP remedy, as GWP would not generate any appreciable volume of waste or wastewater.

3. ALTERNATIVE 2 REMEDY: SOURCE CONTROL WITH CONTINUOUS CONTAINMENT SYSTEM

The Alternative 2 remedy, source control with continuous containment system, includes the completed source control supplemented by the construction of a cutoff wall that would extend from the top of the WAPS perimeter dikes (approximate elevation of 462-465 feet[2]) completely through the highly pervious uppermost aquifer (UA) and penetrate (*i.e.*, anchor) into shale bedrock at an approximate elevation of 375 feet (*i.e.*, a deep cutoff wall). The deep cutoff wall would encircle the perimeter of the CIP portions of the WAPS, with a total length of approximately 5,200 feet and a typical depth of 90 feet below ground surface (bgs). The existing final cover system would be extended over the top of and tied into the deep cutoff wall. This would result in CCR within the WAPS being contained within a continuous system of low-permeability materials and isolated from the surrounding environment on all sides, which includes the highly pervious UA, through:

- The deep cutoff wall, providing lateral containment on all sides of the CCR,
- The existing low-permeability geomembrane final cover system, providing surface containment on the top of the CCR,
- Low-permeability competent shale bedrock, providing base containment below the CCR.

This continuous containment system would provide a physical barrier between the CCR and the surrounding environment. Modeling indicates the continuous containment system is unlikely to result in the buildup of liquids within the contained CCR mass, and therefore supplemental groundwater extraction and/or active gradient control within the WAPS to remove accumulated liquids is not expected to be necessary. Therefore, the continuous containment system would control the source of releases of constituents.

The deep cutoff wall portion of the system would be constructed using either a mixture of soil and bentonite or cement and bentonite and would have a typical thickness of 2 to 3 feet. The cutoff wall would have a typical hydraulic conductivity value of approximately 1×10^{-7} centimeters per second (cm/s) or lower.

A feasibility-level design drawing of the Alternative 2 source control with continuous containment system remedy is provided as **Figure 2** in **Appendix A.**

3.1 Remedy Scoping and Groundwater Modeling Results

The location of the deep cutoff wall portion of the continuous containment system remedy was selected by reviewing physical constraints around the WAPS and designating locations on the DMG property where the wall could feasibly be constructed. The objective of selecting the wall location was to limit impacts to existing site infrastructure and sensitive areas such as wetlands, regulatory floodplains, or areas with documented decurrent false aster plants[3] while also limiting adverse impacts or conflicts with the 2020 WAPS final closure. This assessment resulted in the selection of a wall alignment along and outside of the existing site access road around the crest

[2] All elevations in this report are in the North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

[3] The decurrent false aster (*Boltonia decurrents*), a threatened species in Illinois, has been identified along the southern boundary of the OWAP [12, 13, 14]

of the WAPS perimeter dikes, which is not within regulatory floodplains or known wetlands, avoids known decurrent false asters, and provides generally level alignment for the wall. The location also allows the cutoff wall to act as a lateral barrier between the CCR contained within the OWAP and the surrounding environment and reduces, but does not eliminate, conflicts with the 2020 WAP closure. The location of the wall would allow the final cover to be extended over the top of the wall as surface containment, while also allowing the wall to completely encircle CCR within the WAPS.

Other locations were considered and determined to be infeasible for construction of the deep cutoff wall portion of the continuous containment system remedy. One location was outside the OWAP perimeter dikes, such as at the toe of the OWAP dikes or within adjacent portions of the OWAP that were closed by removal of CCR (*i.e.,* the OWPP). This is because these areas are within the 100-year floodplain of the Illinois River and are often flooded by seasonal high-water events, located near or beyond DMG property boundaries, in areas that are considered regulatory wetlands, or home to rare and endangered species (*e.g.*, decurrent false aster known to be present along the southern boundary of OWAP [11]). Therefore, both permitting and constructing the cutoff wall portion of the remedy in these areas was determined to be impracticable due to a high likelihood for flood-related impacts during wall construction, multiple floodplain and wetland-related permits required for the construction, the potential need to purchase or obtain access easements from adjacent landowners, the potential for a release of impacted stormwater and/or sediments to the wetlands or river during construction, and the potential adverse impacts to rare and/or endangered species previously discussed. Adjacent wetlands, floodplains, and rare plant locations are shown on the drawings provided in **Appendix A**.

Groundwater modeling estimated that, for an assumed start of remedial action in 2028, GWPS would be met for all wells in the monitoring network in 2061. This is 33 years after the start of corrective action that was assumed in the groundwater model. The attached Groundwater Modeling Technical Memorandum, which provides additional information on the updated groundwater modeling used to support the feasibility-level design of this remedy, is provided in **Appendix B1**.

3.2 Remedy Implementation

Implementation of the Alternative 2 source control with continuous containment system remedy is expected to include multiple tasks spread out over three phases, including pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action operations, maintenance, and closeout (Phase 3). Information for each phase is described in this section.

3.2.1 Phase 1: Pre-Construction Activities

Pre-construction activities would include further pre-design investigation, obtaining permits from other agencies, completing the final design of the remedy, and selecting a remedy implementation contractor via a bidding process. Information associated with each of these activities is described below.

- Completing pre-design investigation, final design, and bid activities, including:
  - Completion of final pre-design subsurface investigations, laboratory soil testing, engineering calculations, bench-scale testing of proposed wall construction materials, design drawings, specifications, and a construction quality assurance plan.

  - Bidding and selection of a cutoff wall construction contractor.

- Obtaining permits from other agencies including:
  - A general stormwater permit for construction site activities through IEPA, including construction of stormwater controls and other best management practices (BMPs) such as silt fences.
  - An Illinois Department of Natural Resources (IDNR) Office of Water Resources, Dam Safety modification permit would be likely be required for modification of the WAPS embankment.
  - A National Pollutant Discharge Elimination System (NPDES) permit modification to allow CCR-contact stormwater generated during construction to be collected and transmitted to the existing on-site treatment pond for discharge to the Illinois River via Outfall 003.

3.2.2 Phase 2: Corrective Action Construction

Corrective action construction would be initiated after pre-construction activities are complete. It would include mobilizing construction equipment to the site, preparing the site for construction activities, construction of the cutoff wall (which would include removal and replacement of existing subgrade soils with low-permeability wall materials), and performing post-construction and site restoration activities including integrating the deep cutoff wall with the completed final closure to provide the continuous containment system.

Information associated with each of these activities is described below.

- The contractor would mobilize equipment and materials to the site, install stormwater BMPs around the construction area, construct a staging and laydown area, and construct a level working pad and/or temporary construction access roads along the cutoff wall alignment.
- The cutoff wall alignment would likely conflict with the completed geosynthetic and soil final cover system for the WAPS. To allow for cutoff wall construction, the final cover system would be temporarily removed in these areas.
  - This would include stripping topsoil and cover soil from the geomembrane, stockpiling the materials in the former Hennepin Coal Yard for future final cover restoration, removing the geosynthetics, and disposing of them in an off-site landfill.
  - Any conflicting site infrastructure (i.e., access roads, piezometers, monitoring wells, stormwater channels, stormwater letdown structures, pressure relief vents) would also be removed as part of the activities.
- A level, approximately 60-feet wide working pad and temporary construction access road would be constructed along the cutoff wall alignment to allow construction equipment (*i.e.*, cranes, haul trucks, light vehicles) access and traffic.
  - Due to the expected high ground pressures of the construction equipment, there is a high potential for damage to final cover system geosynthetics beneath access roads and working pads, even in areas outside of the cutoff wall alignment itself. For this reason, the final cover system soils and geosynthetics would also be removed beneath the footprint of the working pad and access road, in the same manner as final cover system removal completed directly beneath the cutoff wall alignment.

- A temporary contact water stormwater management system would be constructed to collect CCR-impacted stormwater generated during construction. This is expected to include temporary drainage sumps, pumps, and piping required to collect contact stormwater and pump it to the existing on-site treatment pond for discharge via NPDES Outfall 003.
- A temporary on-site batch plant and/or material handling system would be established for the purpose of generating low permeability backfill for the cutoff wall. This would include either mixing bentonite with the subgrade soils or producing a cement-bentonite slurry to place into the wall.
- A geotechnical monitoring system would be installed to monitor the WAPS perimeter dikes for movement when the dike is loaded with heavy construction equipment with the potential to destabilize the slurry construction. The monitoring system may consist of survey monuments, survey prisms, inclinometers, piezometers, and/or other appropriate monitoring devices.
- The wall would likely be constructed utilizing either crane-mounted conventional construction equipment (*i.e.,* clamshell, slurry cutter, and/or hydromill); however, other innovative methods could be utilized if determined to be appropriate based on site-specific subsurface conditions and constructability considerations.
- Installation of the cutoff wall would occur concurrently with the removal of some of the subsurface soils (soil-bentonite walls) or all of the subsurface soils (cement-bentonite wall).
- The wall would likely require installation in discontinuous panels (*i.e.,* primary panels) with secondary panels installed for connection after the primary panels have sufficiently cured/hardened, in order to support the stability of the sides of the wall during construction and reduce the destabilizing effects of slurry within the perimeter embankments.
- Excavated soils (*e.g.,* spoils) would be placed into off-road dump trucks and hauled to the former Hennepin Coal Yard for temporary stockpiling.
- After the cutoff wall construction is complete, CCR-impacted cutoff wall spoils and/or work pad materials would be managed either off-site or beneficially used within the Hennepin East Ash Pond as compacted contouring fill beneath the final cover system.
  - Cutoff wall spoils that are not CCR-impacted would be disposed of on-site at the HPP.
- The final cover system would then be restored. This would include placing new geosynthetics and tying them into the existing, un-damaged geosynthetics, extending the final cover system across the deep cutoff wall to provide the continuous containment system, and replacing the cover soil and topsoil with the previously removed and stockpiled final cover system soils.
- The temporary contact water management system would be decommissioned as part of final cover system replacement.
- Piezometers, monitoring wells, pressure relief vents, stormwater channels, stormwater letdown structures, and access roads damaged or removed during construction would also be replaced, and the final cover system would be revegetated via seeding.
- Temporary BMPs would also be installed during the site restoration period, if required in accordance with site land disturbance permits. The BMPs would be removed once vegetation is established.

3.2.3 Phase 3: Corrective Action Operations, Maintenance, and Closeout

Corrective action operations, maintenance, and closure would be initiated after corrective action construction is completed. Phase 3 would include performing corrective action groundwater monitoring, and, after GWPS have been met, performing corrective action closeout and completion activities. Information associated with each of these activities is described below.

- Corrective Action O&M
  - No corrective action O&M is required for the deep cutoff wall or shale bedrock portions of the continuous containment system remedy, as these features are passive, below-grade structure without maintenance or operational needs.
  - Maintenance of the WAPS final cover system portion of the continuous containment system remedy would continue in accordance with current post-closure care O&M practices.
- Corrective Action Groundwater Monitoring
  - Regular corrective action groundwater monitoring would be conducted utilizing a corrective action groundwater monitoring system designed in accordance with 35 I.A.C. § 845.680(c), which specifies that wells must be installed within the plume of contamination that lies beyond the waste boundary.
    - Samples would be collected for COCs required by 35 I.A.C. § 845.600(a)(1). Samples would be collected on a quarterly basis initially and potentially reduced to a semiannual basis once five years of monitoring have occurred, in accordance with 35 I.A.C. § 845.650(b)(4).
    - Monitoring results would be submitted to IEPA after each monitoring event, in addition to an annual groundwater monitoring and corrective action report, in accordance with 35 I.A.C. § 845.640(e). The annual corrective action report would include an evaluation of the actual performance of the remedy relative to the remedy's expected performance.
    - Routine maintenance of the monitoring well system would be conducted during the monitoring period. This would include inspection of the wells, making repairs to the wells (as and if needed), and rehabilitation and/or replacing the wells to improve performance (as and if needed).
  - If the remedy does not achieve its expected performance, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. § 845.680(b).
- Adaptive Management during Monitoring
  - Groundwater monitoring results would be evaluated and documented in the monitoring reports submitted to IEPA, in accordance with 35 I.A.C. § 845.610(e).
  - Remedy progress evaluation as part of adaptive site management may include additional investigation to inform updates to the conceptual site model (CSM), groundwater, and geochemical models.
  - If remedy progress does not correspond with expectations, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. § 845.680(b).

- Corrective Action Completion
  - After GWPS have been met for all compliance wells for a period of three years, corrective action would be considered complete, per 35 I.A.C. § 845.680(c).
    - It should be noted that this could occur prior to or after completion of the 30-year post-closure care groundwater monitoring requirement associated with 35 I.A.C. § 845.780(c).
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification would then be submitted to IEPA, in accordance with 35 I.A.C. § 845.680(e).

3.2.4 Remedy Implementation Schedule

A feasibility-level implementation schedule for the Alternative 2 source control with continuous containment system remedy is provided in **Table B** below.

Table B. Feasibility-Level Implementation Schedule – Alternative 2 Source Control with Continuous Containment System

Implementation Phase	Implementation Task	Timeframe (Preliminary Estimates)
1: Pre-Construction Activities	Agency Coordination, Approvals, and Permitting	18 to 24 months
	Final Design and Bid Process	24 to 36 months
	Timeframe to Complete Corrective Pre-Construction Activities	42 to 60 months after CAP Approval
2: Corrective Action Construction	Corrective Action Construction	18 to 24 months
	Timeframe to Complete Corrective Action Construction	18 to 24 months
3: Corrective Action Monitoring and Closeout	Corrective Action Monitoring (Time to Meet GWPS)	396 months (33 years)
	Corrective Action Groundwater Confirmation Monitoring	36 months
	Corrective Action Completion	6 months
	Timeframe to Complete Corrective Action O&M and Closeout	438 months
Total Timeline to Complete Corrective Action (after approval of Corrective Action Plan)		498 to 522 months (42 to 44 years)

3.2.5 Management of Extracted Groundwater

No groundwater extraction would occur under this remedy.

3.2.6 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) Information

As requested by Gradient, the following information required by 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) has been developed for the remedy. The information was developed based on preliminary-level information contained within the CMA for the HEN WAPS and then refined based on additional feasibility-level design activities performed as part of the development of this CAAA-SIR.

- Potential Need for Replacement of the Remedy – 35 I.A.C. § 845.670(e)(1)(H)
  - The deep cutoff wall and underlying shale bedrock remedy would be unlikely to require replacement, as the cutoff wall would be a robust, engineered, and maintenance-free subsurface structure.
  - The final cover system portion of the remedy will require continual maintenance in accordance with existing post-closure care plans, but is an engineered and passive structure that is unlikely to require replacement.
- Degree of Difficulty Associated with Constructing the Remedy – 35 I.A.C. § 845.670(e)(3)(A)
  - The remedy would require mobilizing specialty equipment to the site (*i.e.,* large cranes, clamshells, or slurry cutters) to construct the deep cutoff wall in addition to other supporting equipment (*i.e.,* batch plants, excavation, and grading equipment).
  - While cutoff walls are routinely constructed to similar depths in similar geologic environments, they often encounter difficulties during construction. The difficulties could include encountering especially pervious layers and resulting slurry loss or encountering obstructions that require specialized techniques and/or equipment to advance past, or instability or caving in the sidewalls prior to hardening of the slurry backfill. These difficulties can be problematic at the WAPS due to the known presence of boulders and cobbles within the subsurface soils. While these challenges can be addressed during cutoff wall construction, they may result in schedule delays.
  - The cutoff wall would be installed through an existing CCR surface impoundment embankment that is also a dam regulated by IDNR. This would require placing heavy construction equipment (*i.e.*, cranes) at the crest of the embankment as well as placing a slurry fluid within the embankment that may cause temporary destabilization of the embankments until curing occurs. While these challenges are common to constructing cutoff walls in embankments, additional engineering assessments and monitoring systems/programs would be required to monitor the embankment for signs of distress (*i.e.*, deformation, cracking) during cutoff wall construction and take appropriate means to stabilize the embankment if signs of potential instability are noted.
    - Furthermore, the act of placing the crane at the top of the embankment and placing slurry within the embankment may result in temporary destabilization of the embankment relative to current conditions. This would be addressed by performing detailed engineering assessments to evaluate the stability of the WAPS embankments during cutoff wall construction.
  - CCR-contact stormwater management is an obligatory part of construction that is necessary in order to comply with site-specific land disturbance permits and reduce the potential for the release of contact stormwater into the adjacent wetlands or Illinois River. This would require the installation and operation of a contact stormwater management system to pump contact stormwater approximately 1.3 miles to the existing on-site treatment pond for discharge via NPDES Outfall 003. Additional management of outfall water quality may also be required during construction.
  - The performance of the cutoff wall portion of the remedy would be dependent on the construction techniques of the wall, in order to avoid gaps, voids, or other discontinuous features or defects in the wall. Continuous quality control monitoring would be required

during construction as part of construction quality control and quality assurance activities in order to avoid these features. The wall may also require post-construction quality assurance activities (*i.e.,* coring and testing) to verify the quality of the constructed barrier.

  - The performance of the deep cutoff wall portion of the remedy would also be dependent on the actual hydraulic conductivity of the wall. This would require continual monitoring, quality control testing, and quality assurance testing of slurry mixing and placement or soil-bentonite mixing to verify that the as-designed mix is utilized.

- Expected Operational Reliability of the Remedy - 35 I.A.C. § 845.670(e)(3)(B)
  - The continuous containment system wall is expected to have high operational reliability if the deep cutoff wall is constructed in accordance with standard design specifications for barrier walls and the final cover system is maintained in accordance with the existing post-closure care plan. This is because the remedy provides continuous surface, lateral, and lower containment of the CCR using both engineered and natural inert, low-permeability groundwater flow barriers (*i.e.*, the existing cover, the deep cutoff wall, and competent shale bedrock).
  - Temporarily removing portions of the completed WAPS final cover is required to allow for installation of the cutoff wall portion of the remedy. The final cover system will be restored around one year later. This process may allow additional stormwater to percolate into the CCR while the final cover system is removed and potentially cause a temporary reversal of some of the positive effects of the completed final cover system (*e.g.*, source control).
    - However, these effects would be expected to diminish after the final cover system is repaired, as the continuous containment system will then be present.
- Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies - 35 I.A.C. § 845.670(e)(3)(C)
  - Agency permits would need to be obtained from IEPA for construction stormwater controls and BMPs, in addition to a joint water pollution control construction and operating permit and IDNR Dam Safety modification permit to allow for modifications of the WAPS embankment.
  - A modification to the site's NPDES permit would also be required to allow for the discharge of CCR-contact stormwater generated during construction. These permits typically take 18 to 24 months to obtain.
- Availability of Necessary Equipment and Specialists - 35 I.A.C. § 845.670(e)(3)(D)
  - Construction of the deep cutoff wall portion of the remedy would require a specialized contractor experienced with construction of similar types of walls in similar geologic environments (*i.e.,* the Illinois, Mississippi, and/or Ohio River Valleys), particularly in environments with a prevalence of boulders and cobbles in the subsurface. The contractor would likely need specialized equipment, such as large cranes, clamshell buckets, slurry cutters, hydromills, batch plants, or other types of specialized equipment.
  - Specialists in cutoff wall design and construction would also need to be utilized during the design and construction phase of the cutoff wall. The specialists would include design

engineers, construction managers, and contractor staff experienced with cutoff wall construction and equipment operation.

- Monitoring of the WAPS embankments during cutoff wall construction would require specialists in geotechnical instrumentation (*i.e.,* inclinometers, survey prisms, vibrating wire piezometers) and visual observation of embankments for signs of distress. Additionally, a specialized drilling and instrumentation installation contractor would be needed to construct the geotechnical instrumentation system. Surveyors or other specialists may also be needed to collect routine readings from the system.
- These types of equipment and specialists have been utilized in the past for other similar types of deep cutoff wall design and construction projects. However, there may be shortages associated with the equipment and specialists, due to high existing backlog for specialty ground improvement contractors and design specialists who are supporting similar types of projects in the electric utility, dam/levee, and other market sectors.
- Specialists, with the necessary equipment, experienced with geosynthetics design and installation, specifically with seaming new geosynthetics to an existing final cover system, would be required for the final cover system restoration portion of the remedy. These types of equipment and specialists are available; however, they may have a high existing backlog due to ongoing projects in the solid waste management, electric utility, and other market sectors.
- Equipment and specialists for field data collection, groundwater sampling, analysis, and periodic corrective action groundwater monitoring and reporting would be required for the remedy. As described in **Section 2.2.3,** the equipment and specialists required to support these activities are currently performing routine groundwater monitoring in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring in this alternative.
    - The equipment and specialists required for site groundwater monitoring and analysis are currently performing this work in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring for this alternative.

- Available Capacity and Location of Needed Treatment, Storage, and Disposal Services - 35 I.A.C. § 845.670(e)(3)(E)
    - Wastes generated during cutoff wall construction would be limited to geosynthetics and other debris from removing the final cover system, cutoff wall spoils, and contact stormwater.
        - Geosynthetics and other debris would be disposed at an off-site landfill. Multiple off-site landfills are located within the region, and all are expected to have sufficient volume to receive the relatively low quantities of geosynthetics and other debris.
        - Cutoff wall spoils containing CCR-impacted material would be temporarily staged on-site during construction and ultimately be managed either off-site or beneficially utilized as compacted contouring fill on-site beneath the Hennepin East Ash Pond final cover system during restoration. This would require coordination with the East Ash Pond closure.

    - Cutoff wall spoils that do not contain CCR-impacted material would be disposed of at an appropriate on-site location at the HPP.
    - Contact stormwater would be pumped to the existing on-site treatment pond for discharge via NPDES Outfall 003. The treatment pond and outfall previously received much higher flow volumes during operation and are therefore expected to have sufficient capacity for contact stormwater management.
- No wastes would be generated during operation of the continuous containment system; therefore, no additional treatment, storage or disposal services would be required with the source control with cutoff wall remedy.

4. MATERIAL QUANTITY, LABOR, AND MILEAGE ESTIMATES

Estimates of material quantities, total labor hours, and mileage were prepared for Alternative 2 source control with continuous containment system remedy, to support Gradient in preparing a CAAA. Estimates were not prepared for Alternative 1 source control with GWP as the alternative does not require remedial construction or operations and maintenance of a physical remedy.

These estimates were prepared utilizing the following approach:

- Major implementation (*e.g.*, construction) components and line items were identified in accordance with the remedy implementation narratives contained within this CAAA-SIR.
- Construction quantities were estimated based on quantity estimates for volumes, areas, and units, as obtained from the feasibility-level engineering drawings and schedules included within this CAAA-SIR.
- RS Means Heavy Construction Cost Data (RS Means) [12] was utilized to estimate the crew size, equipment description, and daily output associated with each line item.
- For line-items where RS Means data was not available, the crew size, equipment description, and daily output were estimated based on Ramboll's experience, information from contractors, and/or information from material suppliers.
- For the Alternative 2 source control with continuous containment system remedy, daily construction and oversight were estimated assuming an average one-way commute of 35 miles for each individual working on-site. The number of working days and hours per week were estimated from the construction schedule developed for each remedy.
- Estimates of material delivery miles were prepared based on Ramboll's experience.

The detailed material quantity, labor, and mileage estimates are provided in **Appendix C** for each alternative.

EXECUTIVE SUMMARY

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Groundwater Modeling Technical Memorandum on behalf of the Hennepin Power Plant (HPP), operated by Dynegy Midwest Generation, LLC (DMG), in accordance with requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments. This document presents the groundwater flow and transport models for the West Ash Pond System (WAPS) and the results of predictive groundwater modeling simulations for proposed corrective action. The coal combustion residuals (CCR) unit is the WAPS, composed of the Old West Polishing Pond (OWPP) and the Old West Ash Pond (OWAP), both closed in 2020 (Vistra identification [ID] number [No.] 804). The WAPS was operated from the 1960s until 1996. The Illinois Environmental Protection Agency (IEPA)-approved closure of the WAPS consisted of excavation of ash material from the OWPP, consolidation of ash from the OWPP into the OWAP, and capping of the OWAP with a geomembrane and soil cover. The closure plan for the WAPS was described in Closure and Post-Closure Care Plan (Geosyntec, 2017) and approved by the IEPA in a letter dated June 19, 2018.

A detailed summary of site conditions was provided in the Hydrogeologic Site Characterization Report (HCR; Natural Resources Technology, Inc. (NRT), 2017a). The principal stratigraphic layers encountered at the WAPS and adjacent areas (from top to bottom) are CCRs consisting primarily of fly ash with lesser amounts of bottom ash and slag, alluvial fine-grained silts and clays classified as Cahokia Alluvium, alluvial fine to medium sands, and sand and gravel with boulders deposited by glacial meltwaters, which are classified as Henry formation. Bedrock is encountered at an approximate elevation of 375 feet[1] and consists of interbedded layers of shales and thin limestone, sandstone, and coal beds.

The overall groundwater flow regime consists of surface recharge to groundwater, with flow directions towards the Illinois River. Flow patterns within the site hydrostratigraphic units are typically horizontal, with components of converging vertical (upward) flow near and below the river. Under typical post-closure conditions, groundwater flow directions at the OWAP are north, towards the river. During the former operation of the impoundments, high local recharge to groundwater from sluicing of ash created radial flow conditions near the impoundment; while groundwater flow was still predominantly towards the river, some of the groundwater beneath the impoundment flowed outwards towards the south and west of the OWAP.

Boron transport in groundwater was evaluated with the groundwater model because it is a primary indicator of coal ash leachate, exceeds the Class I standard, is mobile in groundwater, and is more representative of coal ash leachate than sulfate at this site, which may originate from other anthropogenic or natural sources. Boron enters groundwater via vertical recharge through coal ash, and horizontal groundwater flow through coal ash where it lies below the water table. Solutes are transported in groundwater towards the Illinois River which is the primary receiving body of water adjacent to the WAPS. The conceptual transport model assumes that boron concentration in leachate does not vary as a function of time, although the volume and flux rate of leachate decreases over time as a function of pond dewatering and capping. It is assumed in this model there is no removal of mass from the groundwater system via adsorption or decay.

[1] All elevations and total heads in this report and the subsequent attachments are referenced to North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

For modeling purposes, it was assumed that boron would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]) which is a conservative estimate for predicting contaminant transport times in the model.

This Correction Action Plan (CAP) model update is a revision to the model developed for the WAPS in 2014 and updated in 2017 (NRT, 2017b). Generally, the model boundaries, parameters, and calibration (heads, flow directions, and boron distributions) were retained from the 2017 model; however, some small adjustments were made to parameter and boundary conditions to preserve model calibration (flow and transport) following updates to the model resolution and base-of-ash elevations within the OWAP. The objectives of the model update were to refine model specifications to include data collected since 2017 (*i.e.,* the closure conditions of the OWAP) while maintaining the previous quality of calibration, and to generate results consistent with the 2017 model predictions.

Model prediction scenarios were simulated to evaluate potential groundwater corrective action alternatives for boron in groundwater. Prediction models were evaluated from projected remedy completion of 2028 to 200 years in the future (2228). The objective of predictive modeling of the corrective action scenarios listed below is to simulate boron concentrations in groundwater for different corrective actions to evaluate if implementation of these actions will reduce the amount of time to meet the groundwater protection standard (GWPS) of 2 mg/L for boron at the nine compliance monitoring wells; and, within groundwater at the site.

The following corrective action alternatives were simulated:

- Alternative 1, Source Control with Groundwater Polishing (GWP)
- Alternative 2, Source Control with Cutoff Wall
  - 2a, Continuous Containment System with Deep Cutoff Wall
  - 2b, Partial-Depth Cutoff Wall
  - 2c, Shallow Cutoff Wall
- Alternative 3, Source Control with In-situ Solidification/Stabilization (ISS)

Simulation of the corrective action alternatives indicated that concentrations of boron at the nine site compliance wells have decreased as a result of the closure in 2020 and will continue to decrease. Each of the five alternatives results in reduction of boron at the compliance wells within approximately 30 years following corrective action. Small differences in cleanup time were identified for each of the different alternatives. Comparison of predicted concentrations at the compliance wells indicates that the time to reach GWPS is similar across each of the evaluated remedies, with Alternatives 1, 2b, 2c, and 3 reaching GWPS in 2055 (27 years after implementation), and Alternative 2a reaching GWPS by 2061 (33 years after implementation).

1. INTRODUCTION

1.1 Overview

NRT, an OBG Company, documented site-specific MODFLOW and MT3DMS groundwater flow and transport models in a Groundwater Modeling Report (GMR) submitted to IEPA in 2017 (Appendix D of the Closure and Post-Closure Care Plan; Geosyntec, 2017). The groundwater modeling activities documented in the 2017 GMR were performed to support closure of the WAPS at the Hennepin Power Station, Hennepin, Illinois. This document presents the MODFLOW and MT3DMS groundwater flow and transport models developed in 2023 (CAP model update) to meet the Corrective Action requirements of 35 I.A.C. § 845.220(c)(2) and 845.670. These models contain minor refinements to reflect current conditions at the now-closed WAPS and enable improved simulation of future conditions.

Closure of the WAPS consisted of excavation of ash material from the OWPP, consolidation of ash from the OWPP into the OWAP, and capping of the OWAP with a geomembrane and soil cover. The closure plan for the WAPS was described in Closure and Post-Closure Care Plan (Geosyntec, 2017) and approved by the IEPA in a letter dated June 19, 2018. The WAPS closure was completed in 2020 (Dynegy, 2020a; Dynegy, 2020b).

Site hydrogeology and groundwater quality are summarized below , and described in detail in a separate Hydrogeologic Characterization Report (NRT, 2017a) and the Nature and Extent Report (Ramboll, 2024b) The Hydrogeologic Investigation Report was completed to summarize data collected to comply with the requirements of Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257, herein referred to as the Federal CCR Rule, as well as comprehensive data collection and evaluations from prior hydrogeologic investigation reports completed at the site. In addition, Hydrologic Evaluation of Landfill Performance (HELP) modeling was conducted to enable estimation of the time required for hydrostatic equilibrium of groundwater to be achieved beneath the final cover system of the WAPS. The HELP modeling also provided percolation rates for existing conditions and predicted cap scenario that were used as inputs in the groundwater flow and transport model. A description of the HELP model inputs and modeling results are found in the Hydrostatic Modeling Report (NRT, 2017c). Groundwater transport modeling was performed to assess the effects of impoundment closure on groundwater quality. Model development and calibration is documented in **Section 2**. The model prediction results are presented in **Sections 4** and conclusions are summarized in **Section 5**.

1.2 Background

1.2.1 Site History

The Hennepin Power Station has two coal-fired generating units with a total capacity of 280 megawatts (MW). The units were constructed in 1953 and 1959, respectively. DMG operated the WAPS at the Hennepin Power Station from 1952 until late 1996 when the WAPS was removed from service.

The impoundment originally consisted of three ponds: Pond 1 (9.3 acres), at the eastern end of the impoundment, primarily contained bottom ash and slag. Pond 3 (16.4 acres), in the central portion of the impoundment, contained mixed coal ash. A polishing pond (4.7 acres) was located at the western end of the impoundment. The berms, which are 15 feet above grade, were

constructed from locally occurring sandy soils. During operation, service water was used to sluice fly ash, bottom ash, and low-volume wastes to the impoundment.

Closure of the WAPS consisted of excavation of ash material from the OWPP *(*closure-by-removal [CBR]), consolidation of ash from the OWPP into the OWAP, and capping of the OWAP with a geomembrane and soil cover. The WAPS closure was completed in 2020 (Dynegy, 2020a; Dynegy, 2020b).

Site Hydrogeology

In addition to the CCR fill material, the four principal stratigraphic layers (from top to bottom) encountered at the WAPS and adjacent areas are:

- Alluvial fine-grained silts and clays;
- Alluvial fine to medium sands;
- Sand and gravel with boulders, deposited by glacial meltwaters and classified as Henry Formation;
- Bedrock, consisting of interbedded layers of shales and thin limestone, sandstone, and coal beds.

The river-laid deposits are classified as Cahokia Alluvium. The Henry Formation sands and gravels make up the upper and lower terraces, contain frequent boulders, and fill the valley beneath the alluvium. An additional stratigraphic layer, loamy and sandy diamicton (*i.e.*, till) of the Wedron or Glasford Formation, was encountered at one location (Boring 32) approximately 2,560 feet (½ mile) south of the western end of the impoundment; however, this layer is not significant to the hydrogeology at the impoundment.

The uppermost bedrock near the Hennepin Power Station, including the WAPS, is the Pennsylvanian Carbondale Formation, which consists of shale with thin limestone, sandstone, and coal beds. Depth to bedrock in this area varies based upon data available from the Illinois Geological Survey (Chenoweth, et al., 1994) A bedrock investigation conducted in 2025 encountered shale bedrock at a depth of approximately 85 feet beneath the WAPS (Ramboll, 2025).

The WAPS lies over both glacial deposits (Henry Formation) and alluvium (Cahokia Alluvium). Pond 1 lies on top of lower terrace glacial sand and gravel deposits. The eastern portion of Pond 3 overlies alluvial sand, while the western portion of Pond 3 and the Polishing Pond overlay silty clay alluvial channel fill deposits. The Cahokia Alluvium and Henry Formation materials together comprise the uppermost aquifer at the WAPS, which extends from the water table to the top of the bedrock. More details are presented in the HCR (NRT, 2017a).

Groundwater elevation data is available beginning in 1993. The Illinois River is the local and regional receiving body of water for groundwater, and river stage is controlled by dams located upstream and downstream. River stage is usually lowest during the months of August through October. The river basin experiences annual spring flooding during the months of March, April, May, and sometimes June, while lesser flooding occasionally occurs during autumn. River stage during high precipitation and/or flood events seasonally rises above adjacent groundwater elevations and in low lying areas of the floodplain, particularly within the Donnelley WMA at wells 32, 33, and 34. Stage of the Illinois River typically measures 441-442 feet elevation during

baseflow conditions (low stage); the 10-year flood level is 457 feet, and annual floods typically reach elevations of 450 feet or above.

Review of groundwater elevation data for the site, including transducer data collected in 2023, indicates that groundwater levels across the system vary system-wide, with variations in head tied to river stage and/or seasonal recharge. Horizontal hydraulic gradients from the WAPS to off-site areas ranges from 0.001 foot per foot (ft/ft) during Illinois River flood stage to about 0.005 ft/ft during normal river stage, yielding a groundwater velocity ranging from 0.1 to 1.1 ft/day (NRT, 2017a).

1.2.2 Groundwater Quality

35 I.A.C. § 845 groundwater monitoring began in 2023. Exceedances[2] to the GWPS were identified for boron, cadmium, lithium, sulfate, total dissolved solids, and arsenic. An Alternate Source Demonstration (ASD) was approved for cadmium. The remainder of the constituents with groundwater exceedances were discussed in the Groundwater Monitoring Data and Detected Exceedances, Quarter 4, 2023 (Ramboll, 2024a) and the Nature and Extent Report (Ramboll, 2024b).

1.3 Conceptual Model

The WAPS overlays alluvium and outwash deposits in the Illinois River valley. The principal stratigraphic layers encountered at the WAPS and adjacent areas (from top to bottom) are CCRs and fill consisting primarily of fly ash with lesser amounts of bottom ash and slag, alluvial fine grained silts and clays classified as Cahokia Alluvium, alluvial fine to medium sands, and sand and gravel with boulders deposited by glacial meltwaters which are classified as Henry formation.

The overall groundwater flow regime within the unlithified materials is consistent with topographically-controlled flow patterns, where infiltration of surface precipitation recharges groundwater and flows north and west near the Site towards the Illinois River. Flow patterns within the site hydrostratigraphic units are typically horizontal, with components converging vertical (upward) flow near and underneath the river. Under typical post-closure conditions, groundwater flow directions at the WAPS are north, towards the river. During the operation of the impoundments, high local recharge to groundwater from sluicing of ash created radial flow conditions near the impoundment; while groundwater flow was still predominantly towards the river, some of the groundwater beneath the impoundment flowed towards the adjacent wetlands located south and west of the WAPS (NRT, 2017a; Ramboll, 2024b).

The CCR materials are the primary source of constituent loading to the CCR porewater (*i.e.*, CCR source water). Over an extended period (*e.g.*, months to years), the CCR source water (*i.e.*, water contained within the interstitial pore spaces of the CCR that can be sampled by low-flow groundwater sampling methods) reaches equilibrium with the CCR materials. The porewater is therefore representative of the mobile phase constituents capable of migrating into the underlying materials and potentially downgradient in groundwater. The WAPS CCR source water is therefore the primary indicator of constituents available to the groundwater and is considered

[2] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of DMG's operating permit application for the HPP WAPS. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, DMG has not identified any actual exceedances.

the primary source term for environmental investigation and fate and transport modeling (Ramboll, 2024b).

Boron was simulated and considered a surrogate for other 35 I.A.C. § 845.600 constituents because (1) it is commonly present at elevated concentrations in coal ash leachate; (2) it is mobile and typically not very reactive but conservative (*i.e.*, low rates of sorption or degradation) in groundwater; and (3) it is less likely than other constituents to be present at elevated concentrations in background groundwater from natural or other anthropogenic sources. The surrogate selected for groundwater flow and transport modeling is conservative (*i.e.*, aqueous concentrations are predominantly affected by physical processes such as dilution and dispersion rather than by chemical attenuation mechanisms) and therefore represent the maximum plume extent. The use of a conservative parameter to represent plume extent and clean-up times is consistent with United States Environmental Protection Agency (USEPA) modeling examples intended for evaluating relative remedy effectiveness (USEPA, 1994) as well as an independent subject matter expert review validating the modeling approach for evaluating closure alternatives (Gradient, 2024).

Conservative parameters are most acutely affected by closure: once the source is controlled via closure, concentrations of surrogate parameters in the groundwater will respond in timeframes consistent with groundwater flow. Source control will control, minimize, or eliminate, to the maximum extent feasible, infiltration of liquids through the CCR (per 35 I.A.C. § 845.750(a)(1)), mitigating the flux of not only the surrogate parameters but all other parameters potentially leaching from the unit. The time to reach the GWPS determined by modeling surrogate parameters correlates to the effectiveness of the proposed closure as source control. Therefore, the existing model is appropriate for assessing the effect of closure on the flux of all CCR SI porewater constituents.

The conceptual model for transport assumes two boron sources: boron that leaches to recharge water during percolation through ash above the water table; and boron that leaches to water that may infiltrate from the sides or base of the CCR unit below the water table. Therefore, mass is added to groundwater via vertical recharge through coal ash, and horizontal exfiltration of water from coal ash where it lies below the water table. Mass is transported along with groundwater toward the Illinois River, which is the primary receiving body of water adjacent to the WAPS. The conceptual transport model assumes that boron concentration in leachate does not vary as a function of time, although the volume of leachate decreases over time as a function of capping.

For modeling purposes, it was assumed that boron would not significantly sorb or chemically react with aquifer solids (Kd was set to 0 mL/g) which is a conservative estimate for predicting contaminant transport times in the model. Boron transport is likely to be affected by both chemical and physical attenuation mechanisms (*i.e.,* adsorption and/or precipitation reactions as well as dilution and dispersion). Physical attenuation (dilution and dispersion) of contaminants in groundwater is simulated in the groundwater computer models. Chemical attenuation mechanisms and their effect on modeled times for exceedances to reach the GWPS are discussed in the Groundwater Polishing Evaluation Report [GPR, Geosyntec, 2025] and summarized in **Section 3.2**.

1.3.1 Correlation of Boron with Sulfate, Lithium, and Arsenic

Boron is considered a surrogate for other parameters that exceed the GWPS that do not have approved alternative source demonstrations (arsenic, lithium, and sulfate) because it occurs above the GWPS in the greatest number of wells and it is the constituent at the site that will likely require the longest time to achieve the GWPS. In addition, comparisons of observed sulfate and lithium to boron concentrations (**Figures A and B** below) indicate a statistically significant correlation between these parameters in downgradient uppermost aquifer (UA) wells with exceedances. The correlation coefficient (R^2) and p values (indicator of statistical significance) are also provided on **Figures A and B**. Higher R^2 values (*i.e.,* closer to 1) indicate stronger correlation between parameters. A correlation is considered statistically significant when the p value is lower than 0.05. The p values are less than the target of 0.05, indicating correlations are statistically significant. The statistically significant correlations between sulfate and boron and lithium and boron indicate boron is an appropriate surrogate for sulfate and lithium in the groundwater model, and concentrations of these parameters are expected to change consistent with model predicted boron concentrations.

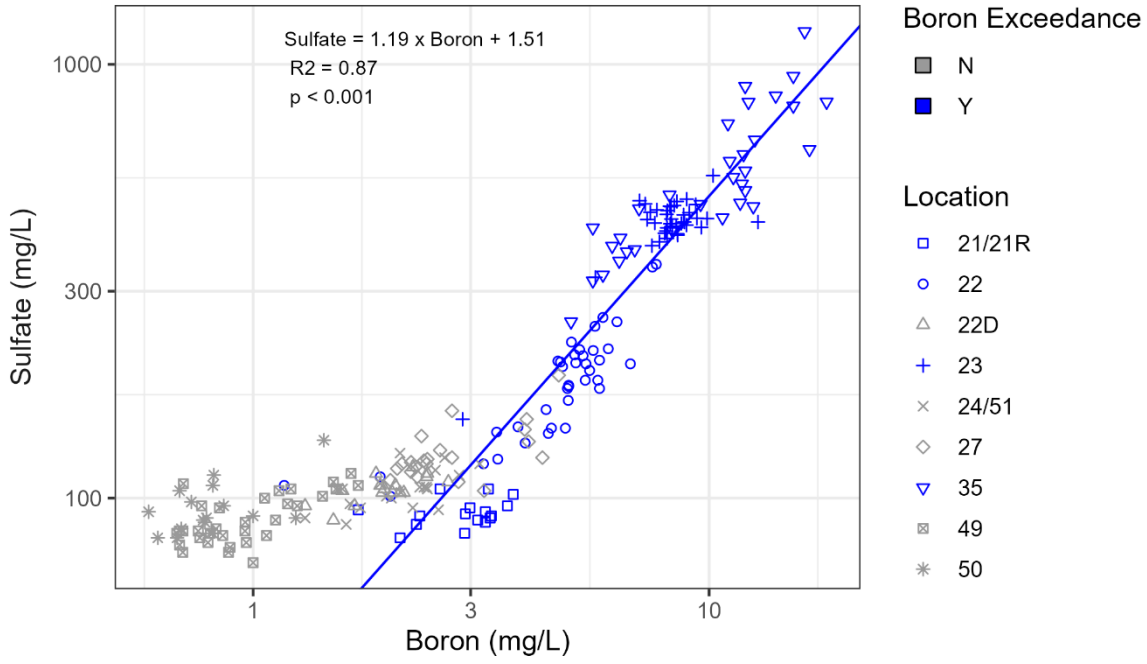

Figure A Correlation of Observed Sulfate and Boron Concentrations in Downgradient Wells (Linear regression for wells with exceedances only)

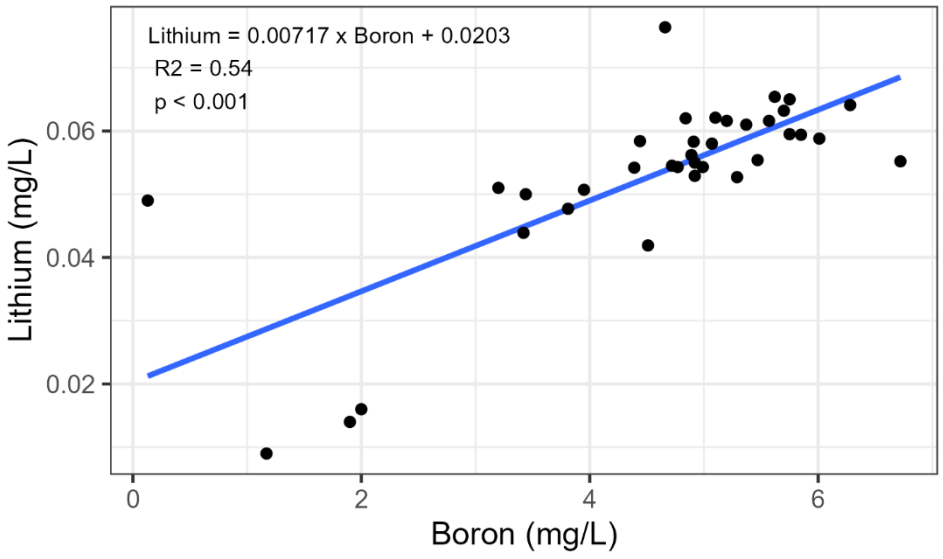

Figure B Correlation of Observed Lithium and Boron Concentrations in Well 22

Boron and arsenic concentrations in downgradient wells with an arsenic (21R and 51) and/or boron exceedance were also evaluated for correlation (**Figure C**). The arsenic data set contains a large number of non-detect values and as a result no statistically significant correlation was found. Arsenic is a reactive CCR constituent, and concentrations within the aquifer will be influenced by geochemical conditions and changes following closure. Localized effects on arsenic geochemistry and expected behavior following closure at these two well locations are further discussed in the Groundwater Polishing Evaluation Report (Geosyntec, 2025) and **Section 3.2**.

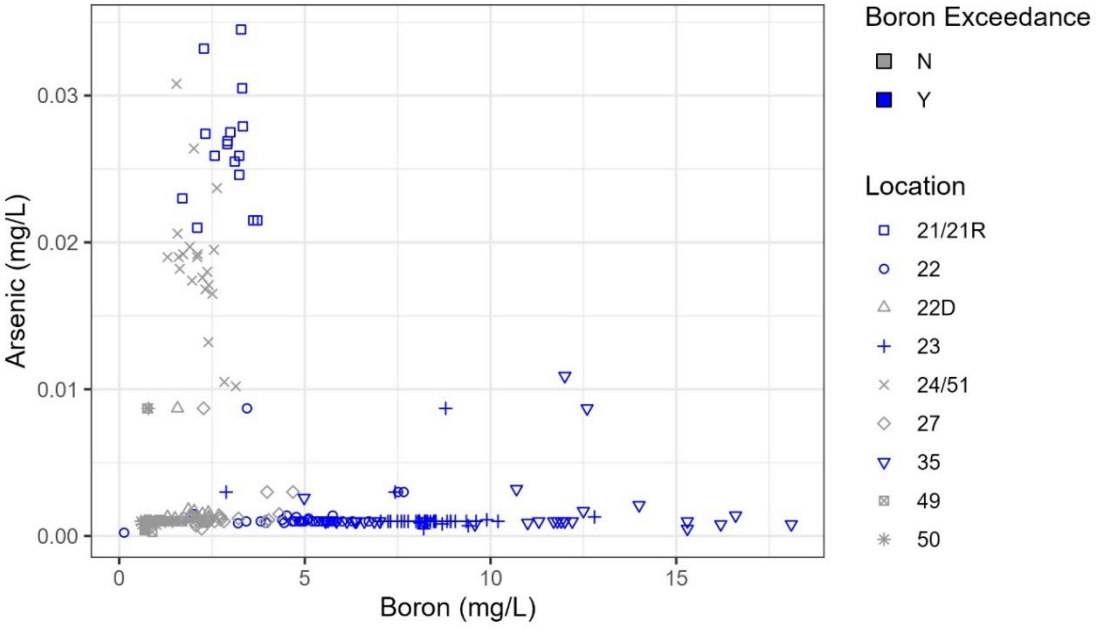

Figure C Correlation of Arsenic and Boron Concentrations in Downgradient Wells

2. GROUNDWATER MODEL DEVELOPMENT AND CALIBRATION

The CAP model update described herein consists of an update to the model developed for the WAPS in 2014 and 2017 (NRT, 2017b). Generally, the model boundaries, parameters, and calibration (heads, flow directions, and boron distributions) were retained from the 2017 model; however, some small adjustments were made to parameter and boundary conditions to preserve model calibration (flow and transport) following updates described in **Section 2.1**. The objectives of the model update were to incorporate information collected since 2017 (including the 2020 closure of the OWAP) while maintaining the previous quality of calibration. Since the model update is predicated on the need to simulate additional corrective action for boron concentrations in groundwater at the site, it was important to retain to the extent practicable the previous model components and calibrations, to ensure that predicted results would be comparable to the 2017 model predictions for WAPS closure.

Specifications and results of the MODFLOW/MT3DMS modeling are presented below. Electronic copies of the model files are provided with this report (**Appendix A**).

2.1 Model Background

Model updates / revisions completed for the CAP model update consist of the following:

- Model Discretization
  - The model extents (domain) and origin were adjusted to correctly align with Illinois state plane coordinates (North American Datum of 1983 [NAD83]).
  - Model resolution was increased, with the horizontal grid spacing decreased from 100 to 25 feet at the WAPS.
  - The bottom of model layer 1 was revised to better match the base of ash elevations within the footprint of the OWAP with the increased resolution of the model. A bottom elevation of 444 feet was assigned to the former OWPP, and model layer 1 bottom elevations were set to 440 feet outside of the WAPS.
  - The bottom of model layer 6 was revised from 390 to 375 feet to better match the estimated bedrock elevation at the WAPS.
- Model Approach and Codes
  - The model time frames were adjusted to simulate current conditions in 2023 and future conditions. The transient calibration model was extended from 2017 to 2023; the previous stress period (2) was extended from 2017 to 2020, and a new stress period (3) was used to simulate closure of the WAPS which was performed in 2020. Stress period 3 was extended to the current time for the calibration model, and until 2028 for the prediction models.
  - The simulation of conditions for unit closure are documented later in **Section 2.4.4**. Simulation specifications for unit closure were consistent with the predictive modeling for capping of the OWAP performed in 2017.
  - New model simulations were performed using MODFLOW 2005, instead of MODFLOW-2000, which was used for the 2017 model simulations. Different versions of MODFLOW are

similar but offer slightly different functionalities that can be useful for various simulated conditions. MT3DMS was retained as the transport model code.

- Boundaries and Parameters
  - Assigned hydraulic conductivity for the glacial outwash material in model layer 6 was decreased to 100 ft/day to retain a consistent transmissivity value after increasing the thickness of the layer.
  - Minor modifications were made to the representation of the Illinois River. The river stage of 441.7 feet National Geodetic Vertical Datum (NGVD29) was retained[3], with the bottom elevation changed to 435 feet to better match river depths. Consequently, the river cells were moved from layer 1 to layer 2 to better match the layer elevations. The river cell conductance values were adjusted in areas away from the WAPS to preserve the calibration and heads from the previous version of the model with the adjustments to the model extent and grid.
  - The conductance values for the river cells used to represent the duck ponds and wetland areas southeast of the impoundments were adjusted to preserve calibration and flow directions with changes to grid cell size.
  - Minor adjustments were made to the alignment of hydraulic conductivity zones to preserve model calibration and flow directions following other minor changes to boundaries and the model grid.
  - Minor adjustments were made to assigned model recharge to preserve model calibration.
  - The no-flow cells in model layer 1 used to represent the areas of the OWAP which were unsaturated under typical conditions were removed to allow model cells to convert from wet to dry during model simulations as warranted by simulated groundwater elevations.
  - Specific yield was decreased from 0.3 to 0.2 to be consistent with porosity (0.2) for each of the transient flow models.
- Transport Model
  - Assignment of a Kd of 1 mL/g for the silt/clay materials was removed to maintain a Kd of 0 mL/g for the entire model domain (no retardation). This is consistent with MT3DMS modeling performed to simulate boron transport at other Luminant/DMG CCR impoundments regulated by 35 I.A.C. § 845.

2.2 Model Approach

Three modeling codes were used to model groundwater flow and contaminant transport: (1) percolation through the cap system was modeled using the HELP model. All details regarding closure configurations and HELP model establishment are presented in a separate Hydrostatic Equilibrium Report (NRT, 2017c); (2) groundwater flow was modeled in three dimensions using MODFLOW 2005; and (3) contaminant transport was modeled in three dimensions using MT3DMS.

[3] All river stages are referenced to NGVD29, which is the USACE gauge datum. The NGVD29 and NAVD88 datums have a difference of around 0.2' in Putnam County, IL. Due to the difference being relatively minor in the context of the model size and accuracy, the river stage elevations were not corrected from the NGVD29 gauge datum to NAVD88.

A three-dimensional groundwater flow and transport model was developed to represent the conceptual flow system described above and then calibrated to match the groundwater monitoring results since 1994. A number of simulations were created to represent different periods of time (below and in **Table A**):

- A steady-state flow model was calibrated to approximate head distributions observed while the impoundment was in service, based on median heads observed from 1994 through 1996 (steady-state flow model)
- The accompanying transport model was calibrated to approximate concentrations observed while the impoundment was in service, based on observations from 1994 through 1996. A 30-year period of impoundment operation was simulated to represent the years 1966 to 1996.
- A transient flow model was created from the steady-state flow model and calibrated to match the decreasing heads measured after the impoundment was removed from service. The model period was December 1996 through December 2016 (transient calibration model stress periods 1 and 2). For this CAP model update, stress period 2 was extended from December 2016 to July 2020.
- The transport model was calibrated to approximate boron concentration trends observed since the impoundment was removed from service. The model period was December 1996 through July 2020 (transient model stress periods 1 and 2).
- New for the CAP model update: A new stress period 3 was added to the transient flow and transport models to simulate closure of the WAPS in 2020. Simulation specifications for the completed closure of the WAPS were consistent with the predictive model for the capping scenario performed in 2017.
- New for the CAP model update: Predictive modeling was performed to evaluate the effects of additional corrective action alternatives on boron concentrations. Flow conditions and concentrations were simulated for a number of scenarios (**Section 3**) from the current time to 2228.

Table A. Model Simulation Stress Periods

Model Stage	Time Period	Model Description
Steady State Flow Model / Transport Model	1966 - 1996	30-year simulation of flow directions and boron transport under operating conditions
	Steady-State Flow Calibration	
	Transient Transport Calibration	
Transient Flow Model and Transport Model	Stress Period 1 (1997 - May 1998)	SP1 – natural dewatering of OWAP after closure
	Stress Period 2 (May 1998 – July 2020)	SP2 – dormant period
	Stress Period 3 (August 2020 - December 2023)	SP3 – post-closure period
Predictive Corrective Action Alternative Simulations (Flow and Transport)	Stress Period 3, extended to 2028	Predictive scenario simulations
	Predictive Scenarios (2028 - 2228)	

2.3 Model Codes

MODFLOW uses a finite difference approximation to solve a three-dimensional head distribution in a transient, multi-layer, heterogeneous, anisotropic, variable-gradient, variable-thickness, confined or unconfined flow system—given user-supplied inputs of hydraulic conductivity, aquifer/layer thickness, recharge, wells and boundary conditions. The program also calculates water balance at wells, rivers and drains.

MODFLOW was developed by the United States Geological Survey (McDonald and Harbaugh, 1988) and has been updated several times since. Major assumptions of the code are: (1) groundwater flow is governed by Darcy's law; (2) the formation behaves as a continuous porous medium; (3) flow is not affected by chemical, temperature, or density gradients; and (4) hydraulic properties are constant within a grid cell. Other assumptions concerning the finite difference equation can be found in McDonald and Harbaugh (1988). MODFLOW 2005 (Harbaugh et al., 2017) was used for this model revision using Groundwater Vistas 8 software for model pre- and post-processing tasks (Rumbaugh, 2020).

MT3DMS (Zheng and Wang, 1998) is an update of MT3D and calculates concentration distribution for a single dissolved solute as a function of time and space. Concentration is distributed over a three-dimensional, non-uniform, transient flow field. Solute mass may be input at discrete points (wells, drains, river nodes, constant head cells), or distributed evenly or unevenly over the land surface (recharge).

MT3DMS accounts for advection, dispersion, diffusion, first-order decay and sorption. Sorption can be calculated using linear, Freundlich, or Langmuir isotherms. First-order decay terms may be differentiated for the adsorbed and dissolved phases.

Major assumptions are: (1) changes in the concentration field do not affect the flow field; (2) changes in the concentration of one solute do not affect the concentration of another solute; (3) chemical and hydraulic properties are constant within a grid cell; and (4) sorption is instantaneous and fully reversible, while decay is not reversible.

2.4 Model Setup

2.4.1 Grid and Boundary Conditions

The discretization of the model consists of six layers, 119 rows, and 178 columns. Variable horizontal grid spacing was used with grid spacing of up to 200 feet at the edges of the model and 25 feet in the area of interest (**Figure 2-1**). Model layers are simulated with uniform top and bottom elevation, with the exception of model layer 1. Variable bottom elevations for model layer 1 were used within the former OWAP to represent the base of ash material (approximately 438-450 feet, 444 feet in the former OWPP, and 440 feet for the remainder of model layer 1).

Flow and transport model domain boundaries were the same for all scenarios. The upgradient (east and south) edge of the model is a no-flow boundary. The downgradient (north) and lateral (west) boundaries are either MODFLOW river (mixed) boundaries (layer 2) or no-flow (layers 1 and 3 to 6). The upper boundary is a time-dependent specified flux (Neumann) boundary, with specified flux rates equal to the recharge rate (from precipitation) or the rate of percolation from the impoundment. The base of the model is a no-flow boundary, at the base of layer 6 (bedrock surface). Additional information on these boundaries is discussed in the subsequent section of this report.

The model included two types of transport boundaries (constant concentration and recharge), both in layer 1. Ash materials within the impoundments were explicitly simulated using both constant concentration cells and recharge. Representation of ash with both boundaries is conservative, in that source concentrations are assigned to active model cells by the constant concentration cells and assigned to inactive or dry cells by recharge concentrations to represent precipitation infiltrating vertically through the ash to the underlying groundwater table. The distribution of these boundaries was adjusted within the ash ponds for the different transport model stress periods to match actual conditions.

2.4.2 Flow Model Input Values

Flow model input values are described below and summarized in **Table 2-1** (Steady-State Flow Model / Transport Model Input Values) and **Table 2-2** (Transient Model Input Values). Sensitivity analysis of input values was performed and documented in the 2017 model update but is not included in this report. Input values were generally retained from the 2017 model, with revisions noted above and in **Table 2-1** and **Table 2-2**.

Layer Bottom

Layer bottoms were set for each of the six layers (**Table B)**. The bottom of model layer 1 was revised from the 2017 model by increasing the grid discretization to better match the base of ash elevations within the footprint of the OWAP. The bottom elevation of model layer 6 was changed from 390 feet to 375 feet to better match the estimated bedrock elevation at the WAPS.

Table B. Model Layer Bottom Elevations

Model Layer	2017 Model	Model Revision
1	440+	437+
2	430	430
3	420	420
4	410	410
5	400	400
6	390	375

Note: Elevations are in feet referenced to NAVD88.

Hydraulic Conductivity

Hydraulic conductivity values were initially derived from field-measured and laboratory tested values and adjusted during calibration. Calibrated values were within observed ranges for the formations present at the site. Vertical anisotropy ratios were set at 2.0 for the sand and gravel and 10 for the silty clay and alluvium. The Kx/Kz ratios represent expected stratification within the formations. **Figures 2-2** through **2-7** present hydraulic conductivity zones and boundary conditions for model layers 1 through 6 for the steady-state and transient calibration models, with a summary of hydraulic conductivity zones in **Table 2-1**. Modifications were made to the boundary conditions and the hydraulic conductivity distribution in model layer 1 at the WAPS to represent closure conditions in stress period 3 (**Figure 2-8**).

Storage

No field data was available defining these terms, so representative values for similar materials were obtained from Smith and Wheatcraft (1993). Sensitivity analysis was not performed on this

parameter. The storage coefficient used in the model was 0.01 and the specific yield was 0.2 (revised from 2017 model). A value of 0.2 was assigned for model porosity for all layers.

Recharge
Recharge rates for the impoundment while in service and during dewatering were assigned during model calibration. Recharge rates for the model domain were adopted from the previous 2017 model and were adjusted during calibration. **Figures 2-9** through **2-12** present the recharge distributions for the steady-state flow model, transient model stress period 1 (1996 to 1997), transient stress period 2 (1998 to 2020), and OWAP closure conditions (stress period 3). A summary of model recharge is provided on **Tables 2-1** and **2-2**.

River Parameters
River boundary cells were used to represent the Illinois River, the waterfowl ponds south and west of the impoundments, and a small creek leading from the waterfowl ponds **(Figures 2-2** and **2-3)**. **Table 2-1** presents stage, river bottom, and conductance for these features used for each of the model simulations. The characteristics of the river boundaries in the model were retained from the 2017 model with a few adjustments to conductance to account for revisions to the model grid and to preserve the previous calibration (head and flow directions). The river was specified in model layer 2 to better match river geometry (depth and stage).

An Illinois River stage of 441.7 feet was retained from the 2017 model, which represents a relatively low stage for typical baseflow conditions. Since groundwater elevations near the OWAP are controlled primarily by river stage, this selection is consistent with simulation of baseflow *(i.e.*, low) groundwater elevations, which is reflected in selected calibration targets for the steady-state flow model.

2.4.3 Transport Model Input Values

Transport model input values are listed in **Tables 2-1** and **2-2** and described below. Sensitivity analysis of transport model inputs was conducted as part of the model development and is documented in the 2017 GMR. Transport calibration was performed during the 2017 model development; minor adjustments to transport parameters were performed to retain calibration of the model with respect to other modifications to grid size and refinements to the base of ash elevations (layer 1 bottom elevations).

Initial Concentration
Initial concentrations for the 1966 to 1996 model were set to zero to represent the background concentration for boron. The final concentrations from the steady-state flow / transient transport calibration model (1966 to 1996) were used as the initial concentrations for the subsequent transient transport model representing the years 1996 and later.

Source Concentration
Boron source concentrations were set during model calibration at values between 7 and 19 milligrams per liter (mg/L), the range observed in monitoring wells near the impoundment. These values were assigned during model calibration conducted in 2017 and retained for the CAP model update.

Ash materials within the impoundments were explicitly simulated using both constant concentration cells and recharge. Representation of ash with both boundaries is conservative, in that source concentrations are assigned active cells by the constant concentration cells and assigned to inactive or dry cells by recharge concentrations to represent precipitation infiltrating

through the ash to the underlying groundwater table. Equivalent concentrations were assigned at each location through recharge (**Tables 2-1** and **2-2**) and using constant concentration cells.

Dispersivity
Dispersivity was set during model calibration, with sensitivity testing performed as part of the 2017 model revision. Transverse and vertical dispersion were estimated according to ratios developed by Gelhar et al. (1985). Calibrated concentrations at some wells distant from the impoundment (wells 26, 30, 31, and 36) were highly sensitive to the longitudinal dispersivity value and to the vertical dispersivity multiplier.

Retardation
Retardation was calculated by the model based on the Kd, which was set during calibration during previous models. The 2017 model assigned a Kd value of 1.0 mL/g to the silty units (channel-fill deposits and alluvium), and a Kd of zero for the sand and gravel units. The simulated Kd was set to zero for the entire model domain (including for the silty units) in the CAP model update to be more consistent with other Luminant/DMG CCR models, and due to low sensitivity of 2017 model results to the Kd for the silty units.

Diffusion
Diffusion was set to 0 square feet per day for the entire model domain.

2.4.4 Simulation of OWAP Closure (Stress Period 3)

Closure of the OWAP was completed in July 2020 in a manner consistent with the specifications simulated in the 2017 predictive modeling, specifically in that the OWPP was removed, and Pond 1 and Pond 3 (the OWAP) were fully capped by a geomembrane cover, comprised of (from top to bottom) a 6-inch vegetative layer, 18-inch protective soil layer, a 0.2-inch geocomposite drainage layer, and a 40-mil geomembrane layer. These conditions were simulated as stress period 3 according to the following model changes:

- All observed ash was excavated from the OWPP and consolidated within the footprint of the OWAP. This was simulated in the flow and transport model by setting the hydraulic conductivity and recharge to the values assigned to the channel fill silts (K of 1.4 ft/day, recharge of 2.2 inch per year (in/yr) and concentration of 0 mg/L), and by removing the constant-concentration cells from the OWPP.
- A structural steel sheet pile wall was installed between the OWAP and the former OWPP. This was represented in the model using the horizontal flow boundary package in MODFLOW. Horizontal flow barriers (HFBs) were assigned to the locations corresponding to the sheet pile installation with an assigned hydraulic conductivity of 1×10^{-6} cm/s (simulated conductance of 2.36×10^{-4} square feet per day [ft^2/day]). This component of the OWAP closure was not simulated in the 2017 model.
- Recharge values in the OWAP were modified to reflect capping of the OWAP with soil and a geomembrane final cover system, consistent with the simulation of this scenario in the 2017 model. Areal recharge was reduced to 0.0024 in/yr across the OWAP, and concentration recharge values of 7 to 19 mg/L were retained to represent concentrations in the limited vertical infiltration through the ash material under the cap (**Table 2-2**).

2.5 Flow and Transport Model Assumptions and Limitations

Simplifying assumptions are necessary when numerically representing the natural environment in a groundwater flow and transport model. Outside of assumptions inherent to the codes used to develop the model, several simplifying assumptions were made, including:

- Recharge instantaneously migrates to groundwater (*e.g.,* rapid vertical infiltration through the unsaturated zone).
- Fluctuations in river stage are short in duration and do not materially affect long-term groundwater flow.
- Source concentrations remain constant over time.
- Boron minimally adsorbs and does not decay, and mixing and dispersion are the primary attenuation mechanisms.
- Cap construction has an instantaneous effect on recharge and percolation because they are constructed over a brief period relative to the length of the model simulation.

The model is limited by the data used for calibration, which adequately define the local groundwater flow system and the source and extent of the plume. These data, collected from 1994 through 2023, are from points near the WAPS. Model predictions of transport distant from the impoundment will not be as reliable as predictions of transport near the impoundment, and the reliability of model predictions decreases with increasing time because changes to the system may occur that the model does not account for.

2.6 Steady-State Flow Model and Transport Model Calibration

Calibration of a groundwater flow or transport model refers to the iterative process of adjusting model parameters and boundary conditions to obtain a reasonable match between observed conditions and simulation results. The primary criterion for evaluating the calibration of a groundwater flow model is the difference between observed and simulated water levels at a set of calibration targets. Calibration targets are a set of field measurements, typically groundwater elevations. For the calibration of a steady-state (time-invariant) model, the goal in selecting calibration targets is to define a set of water level measurements that represent the average elevation of the water table or potentiometric surface at locations throughout the site. The calibration of a groundwater flow model should rely on spatially discrete measurements of groundwater elevation to avoid the potential for interpretive bias that may result from attempting to match a contoured potentiometric surface (Kalikow, 1978; Anderson and Woessner, 1992).

A model residual is defined as the calculated difference between the observed and simulated hydraulic head at a specific location (observed–simulated). Residual statistics are used to quantify and evaluate the relative fit of a model simulation to measured water level targets. The mean of model residuals is a representation of overall model bias; a value near zero is desired. The steady-state flow model and accompanying transport model were developed to represent conditions from 1966 to 1996, during operation of the impoundments. The steady-state flow and transport model targets used in the 2017 modeling were retained for this model revision, with the objective of a similar level of calibration (equivalent match to calibration targets) for the revised flow and transport models. Flow and transport model calibration targets and statistics are presented on **Table 2-3**. Both sets of targets were originally developed from data collected from 1994 to 1996; transport target simulated values were retrieved from the end of the model

simulation (1996). Calibration plots showing observed vs simulated residuals are presented in **Figure 2-13**.

Simulated groundwater model heads (model layer 1) and boron concentrations (maximum concentration from across the model layers) from 1996 are presented in **Figure 2-14**. The mean residual for this calibration is -0.5 (**Table 2-3**). The residual standard deviation indicates the magnitude and spread of the residuals. A residual standard deviation of less than 10 percent of the total range of water level targets is desirable. The residual standard deviation for this calibration is 1.29, which is approximately 10 percent of the observation range (12.7). The residual statistics and simulated hydraulic head distributions indicate a satisfactory model match to observed groundwater flow conditions, and model calibration for the CAP model update is generally consistent with the 2017 model calibration.

2.7 Transient Flow and Transport Model Calibration

The transient flow and transport models, which represented conditions from 1996 to 2023, were qualitatively calibrated by graphically comparing observed and simulated heads and boron concentrations from 1996 to 2023 to provide a qualitative assessment of calibration. Plots comparing simulated and observed heads and boron concentrations at the nine compliance wells are presented in **Figures 2-15** and **2-16**, respectively. The transient model calibration is consistent with the simulation results from the 2017 calibration; consistency with the previous model results was a primary objective of the CAP model update. Several observations regarding the transient model flow and transport model calibrations are further discussed below.

Flow Calibration
As shown in **Figure 2-15**, observed groundwater elevations at site wells fluctuate over time, between approximately 3 and 8 feet, depending on the well location. Generally, simulated heads are consistent with the lower elevation measurements, as is reasonable considering the intended simulation of baseflow conditions (*i.e.,* conditions of low river stage and groundwater elevations). Additionally, wells 22D, 50, 51 were installed after the 2017 model update, therefore these wells were not used as calibration targets during the 2017 model update.

Transport Calibration
Comparison of model simulated boron concentrations in **Figure 2-16** to the calibration obtained by the 2017 modeling (NRT, 2017b) indicates that the CAP model update is generally consistent with the calibration of the 2017 model). However, a number of the compliance wells used for evaluation of this revision were not installed or available for calibration in 2017. The simulated boron concentrations at wells 22D, 49, 50, and 51 are overpredicted. However, since an objective of this model revision was to retain similar predicted conditions and boron concentrations compared to the 2017 modeling, model parameters were not adjusted to improve the calibration at these locations. The overprediction of boron concentrations at these wells is not considered significant for this evaluation since observed concentrations at these four wells are either below the GWPS of 2 mg/L at the current time, or near the GWPS and trending downward. Model calibration to observed concentrations at well 35 is satisfactory from 1997-2019, but do not represent well the concentrations observed at this location from 2020 onward.

3. PREDICTIVE MODELING

Prediction models were evaluated from projected remedy completion of 2028 to 200 years in the future (2228). The objective of predictive modeling of the corrective action scenarios described below is to simulate boron concentrations in groundwater for different corrective actions to evaluate if implementation of these actions will reduce the amount of time to meet the GWPS of 2 mg/L for boron in groundwater. Simulated concentrations of boron were evaluated spatially using maps of maximum boron concentration within each layer at various points in time, and through time-series plots of boron concentrations for the compliance monitoring wells.

Figure 3-1 presents simulated boron concentrations in 2024 and 2028 as initial conditions for evaluation (maximum concentration of boron at each location across all model layers).

3.1 Model Prediction Scenarios

The physical components of each scenario, their representation within the model, and simulation results are presented below. 2028 was used as ”time zero” for completion of the construction of the corrective actions for the model prediction scenarios; discussion of cleanup times in years assumes 2028 as the starting point.

3.1.1 Alternative 1 - Source Control with Groundwater Polishing (GWP)

This scenario is consistent with the closure conditions (capping of the OWAP and Closure-by-removal of the OWPP) initially simulated in the 2017 model report and used to represent current conditions in the revised model as stress period 3. The completed closure and capping of the OWAP and OWPP provides source control for this scenario.

Simulation of GWP was performed by extending stress period 3 from 2028 to 2228. Boron concentrations at the compliance monitoring wells are shown in **Figure 3-2** and **Figure 3-3** presents a map of maximum boron concentrations at 30 years (2058) and 100 years (2128), respectively. Although model simulations were completed for a time frame of 200 years (2228), results were not presented beyond 2128, since concentrations decrease to GWPS at the compliance wells well within this 100-year time frame.

3.1.2 Alternative 2 – Source Control with Cutoff Walls

Alternative 2 consists of installation of a slurry wall cutoff wall surrounding the former OWAP, placed within the OWAP berm from ground surface to various depths with the deep cutoff wall combined with existing site features forming a continuous containment system. Cutoff walls were simulated using the HFB package in MODFLOW, with a thickness of 3 feet and a hydraulic conductivity of 1 x 10^{-7} cm/s. These scenarios assume no changes to the cover system installed during OWAP closure (*i.e.,* any disturbance to the existing cap on the OWAP will be remedied following cutoff wall installation).

- **Alternative 2a – Deep Cutoff Wall (continuous containment system)**. This simulation assumed the cutoff wall was keyed into the relatively impermeable bedrock beneath the overlying unlithified materials, with HFBs simulated in model layers 1 through 6.
- **Alternative 2b – Partial Cutoff Wall**. This simulation assumed the cutoff wall was placed to a base elevation of 400 feet, in order to promote constructability by avoiding cobbles and boulders within deeper layers. HFBs were simulated in model layers 1 through 5.

- **Alternative 2c – Shallow Cutoff Wall**. This simulation assumed the cutoff wall was placed to a base elevation of 420 feet, in order to further improve constructability of the wall. HFBs were simulated in model layers 1 through 3.

Simulation of the cutoff walls assumed remedy completion (begin simulation) in 2028. Boron concentrations at compliance monitoring wells for each of the three cutoff wall alternatives are shown in **Figure 3-4**. Maps of maximum boron concentrations for each of the three cutoff wall alternatives are shown in **Figure 3-5** (30 years, 2058) and **Figure 3-6** (100 years, 2128).

Simulated hydraulics were evaluated for each of the three Alternative 2 scenarios to identify any potential mounding of groundwater inside of the cutoff wall (**Figures 3-5** and **3-6**). Simulation results before and after remedy implementation for the deep cutoff wall (2a) indicated that heads inside the cutoff wall vary from 443.16 to 444.6 feet prior to implementation, and are uniform at 444.19 feet 200 years after implementation. Due to the average of less than 1 foot of head increase within the pond footprint 200 years after implementation of the deep cutoff wall, mitigation of mounding through use of pumping wells or other action was not required to reduce mounding or time to meet GWPS. Minimal change to pre-implementation heads on the interior of the cutoff wall for scenarios 2b and 2c were simulated.

3.1.3 Alternative 3 – Source Control - In-Situ Solidification/Stabilization (ISS)

The third simulated alternative consists of ISS across a portion of the OWAP. The target area for ISS was assigned based upon the estimated extent of CCR present at portions of the WAPS with the lower base elevations. The ISS target area consisted of portions of the OWAP below an elevation of 445.7 feet; portions of the former ash pond where the base of ash elevation was higher than this value were not included in the ISS footprint. **Figure 3-7** depicts the target area for ISS and the estimated thickness of ash where ISS would be conducted at each location.

Simulation of ISS was performed by assigning a hydraulic conductivity of 1×10^{-7} cm/s to the ISS target area. The constant-concentration boundary cells within the footprint were removed to represent immobilization or treatment of dissolved phase mass in the solidified material; however, the recharge concentrations were retained for the OWAP to represent assignment of boron concentration to vertical infiltration through the overlying ash material. The final cover of the OWAP is assumed to be replaced or repaired consistent with the 2017 design specifications (Geosyntec, 2017) following ISS, therefore the simulated rate of vertical surface infiltration through the final cover did not change relative to current conditions for this alternative.

Boron concentrations at the compliance monitoring wells are shown in **Figure 3-8**, and **Figure 3-9** presents a map of maximum boron concentrations at 30 years (2058) and 100 years (2128).

3.2 Assessment of Geochemical Processes

This groundwater transport model estimates the time for boron to reach the GWPS under different potential corrective actions, incorporating the physical components of groundwater polishing. As described above, it was assumed that boron would not significantly sorb or chemically react with aquifer solids (Kd was set to 0 mL/g, which is a conservative estimate for estimating contaminant transport times).

The GPR was prepared as an attachment to the Corrective Actions Alternative Analysis (CAAA). The geochemical modeling effort presented in the GPR supports the assessment of groundwater

polishing as a component of the proposed corrective action by evaluating the potential for chemical attenuation of constituents of concern (COCs) (and for previously attenuated COCs to be mobilized to groundwater as groundwater quality returns to background conditions) as a means of contextualizing the times estimated in the flow and transport model. The GPR also provides a foundation for understanding groundwater chemistry to inform adaptive site management as a key component of the Corrective Action Groundwater Monitoring Program.

As concluded in the GPR:

> *"The results of the groundwater polishing evaluation indicate that chemical attenuation of modeled COCs (arsenic, boron and sulfate) is feasible under current conditions through sorption to iron and aluminum oxide minerals. Though some degree of desorption is predicted with background water interaction, aqueous boron and sulfate (and therefore TDS) concentrations should decrease below the GWPS at all wells in the compliance monitoring network following source control. Remobilization of boron and sulfate is unlikely to affect the estimated time to reach the GWPS based on modeling results. Aqueous arsenic concentrations are predicted to increase at wells with current exceedances following remobilization of arsenic in post-source control conditions. Remobilization may impact the time to reach the GWPS for arsenic. Lithium was not evaluated in the geochemical modeling because lithium concentrations continue to decline following unit closure."*

The results of the GPR geochemical modeling indicate attenuation of COCs boron, lithium, sulfate, and TDS through sorption and chemical mechanisms will complement results of the groundwater transport modeling, in that time to reach GWPS may be shorter than the simulated timeframes. Remobilization of arsenic, which exceeds GWPS at two wells (51 and 21R), may increase the time to reach GWPS from the simulated results.

3.3 Prediction Scenario Results Discussion

Simulation of corrective action alternatives for the OWAP through the next 200 years indicates that concentrations of boron in groundwater will decrease over time regardless of the remedy selected. A summary of predicted boron concentrations and time to meet the GWPS at the compliance monitoring wells is provided in **Table 3-1** and summarized in **Table C** on the next page. As shown, concentrations are expected to fall below 2 mg/L by 2061 for all corrective action alternatives, with the majority of wells (6 of 9) reaching GWPS by 2030 (two years after remedy implementation) regardless of the selected corrective action alternative.

Table C. Estimated Timeframes to Attain GWPS in Groundwater Monitoring Wells†

	Alternative	2 years‡	5 years‡	10 years‡	20 years‡	33 years‡
Percentage of Wells predicted to attain GWPS†	1	67%	89%	89%	89%	100%
Percentage of Wells predicted to attain GWPS†	2a	67%	67%	67%	89%	100%
Percentage of Wells predicted to attain GWPS†	2b	89%	89%	89%	89%	100%
Percentage of Wells predicted to attain GWPS†	2c	67%	89%	89%	89%	100%
Percentage of Wells predicted to attain GWPS†	3	67%	89%	89%	89%	100%

†: Estimated timeframes per the 9 compliance wells
‡: Years counted starting from 2028

3.3.1 Comparison of Corrective Action Alternatives

Comparison of predicted concentrations at the compliance wells indicates that the time to reach GWPS is similar across each of the evaluated remedies, with Alternatives 1, 2b, 2c, and 3 reaching GWPS in 2055 (27 years after 2028), and Alternative 2a reaching GWPS by 2061 (33 years after 2028). Comparison of the engineered corrective action alternatives to GWP shows that Alternatives 2b, 2c, and 3 produce similar cleanup times to Alternative 1, with only slight decreases in time to reach GWPS in 1, 2, or 3 wells (less than 5 years improvement). Alternative 2a results in increased time to reach GWPS in wells 23 and 49 due to reduced advection of groundwater immediately downgradient of the deep cutoff wall (*i.e.,* stagnation of groundwater near wells 23 and 49).

Well 21R is the last to meet GWPS in four of five alternatives; this result is due to the simulated location of this well within the silt and clays, which results in lower groundwater velocities and a consequently longer time for flushing of concentrations after closure of the OWAP in 2020 than for the higher-permeability materials. The cleanup time at well 21R (27 years) is also reduced compared to the cleanup time at this well from the 2017 simulation of OWAP closure; this is due to the assignment of a Kd of 0 mL/g to the silts and clays in this model revision (no retardation of boron).

4. CONCLUSIONS

Existing site-specific three-dimensional groundwater flow (MODFLOW) and transport models (MT3DMS) were revised and employed to evaluate the effectiveness of groundwater corrective action alternatives in reduction of time to reach GWPS in groundwater at the Hennepin WAPS following the closure of the OWAP and OWPP, which were completed in 2020. Boron was selected for simulation of groundwater quality changes resulting from the WAPS. It was assumed that boron would not significantly sorb or chemically react with aquifer solids (Kd was set to 0 mL/g) which is a conservative estimate for predicting contaminant transport times in the model.

Five corrective action alternatives were simulated, consisting of GWP (Alternative 1), three configurations of a cutoff wall surrounding the OWAP (Alternatives 2a, 2b, and 2c), and ISS (Alternative 3). Comparison of predicted concentrations at the compliance wells indicates that the time to reach GWPS is similar for each of the evaluated remedies, with Alternatives 1, 2b, 2c, and 3 reaching GWPS in 2055, and Alternative 2a reaching GWPS by 2061. Comparison of the "engineered" corrective action alternatives to GWP indicates that Alternatives 2b, 2c, and 3 produce similar cleanup times to Alternative 1, with only slight decreases in time to reach GWPS. Alternative 2a, the continuous containment system, results in a longer time to reach the GWPS due to the creation of a stagnant flow zone (area of reduced advection) downgradient of the cutoff wall.

49- L3	7.1	3.4	**5**	33	0	3	4
50-L2	4.4	*0.6*					
51- L6	9.8	*1.1*					
		Year for GWPS	2055 (21R)	2061 (49)	2055 (21R)	2055 (21R)	2055 (21R)

Notes

The GWPS for Boron is 2 mg/L.

Years to reach GWPS are in BOLD for Alternative 1. Blue shading denotes faster cleanup, gold denotes slower cleanup compared to Alternative 1.

Current concentrations are at or below GWPS of 2 mg/L at wells 22D, 49, 50, and 51; concentrations are overpredicted at these wells for 2023.

1 INTRODUCTION

1.1 OVERVIEW

This Groundwater Model Report has been prepared by Natural Resource Technology (NRT), an OBG company, on behalf of Dynegy Midwest Generation, LLC (DMG) to document the impact of proposed capping system for closure of the West Ash Pond Complex (WAPC) at the Hennepin Power Station, Hennepin, Illinois (Figure 1-1). The WAPS is located in the northeast quarter of Section 27, Township 33 North, Range 2 West, Putnam County, Illinois. The impoundment is situated less than 200 feet south of the Illinois River, and comprised of the Old West Ash Pond which includes Pond No. 1, Pond No. 3, and the Old West Polishing (Secondary) Pond. It is bordered to the southeast by agricultural fields, to the southwest and west by low lying floodplain within the Donnelley Wildlife Management Area (Donnelley WMA) administered by the Illinois Department of Natural Resources (IDNR) and to the east by the coal pile and power generating facility.

Site hydrogeology, and groundwater quality are summarized in Section 1, and described in detail in a separate *Hydrogeologic Investigation Report* (NRT, 2017b). The Hydrogeologic Investigation Report was completed to summarize data collected to comply with Federal Coal Combustion Residual (CCR) Rule (40 CFR Part 257) as well as comprehensive data collection and evaluations from prior hydrogeologic investigation reports completed at the Site. A Groundwater Monitoring Plan (NRT, 2017c) and a Groundwater Management Zone Application (NRT, 2017d) are also being prepared to support the closure of the WAPS. In addition, Hydrologic Evaluation of Landfill Performance (HELP) modeling has also been conducted to enable estimation of the time required for hydrostatic equilibrium of groundwater to be achieved beneath the WAPS. The HELP modeling also provided percolation rates for existing conditions and predicted cap scenario that were used as inputs in the groundwater flow and transport model. A description of the HELP model inputs and modeling results are found in the Hydrostatic Modeling Report (NRT, 2017a).

Groundwater transport modeling was established to assess the effects of the proposed capping system on surrounding groundwater quality, and is documented in Section 2. The model calibration and prediction results are presented in Sections 3 and 4, respectively. The report is summarized in Section 5.

1.2 BACKGROUND

1.2.1 Site History

The Hennepin Power Station has two coal-fired generating units with a total capacity of 280 megawatts (MW). The units were constructed in 1953 and 1959, respectively. DMG operated the WAPS at the Hennepin Power Station from 1952 until late 1996 when the WAPS was removed from service. All coal ash disposed to the WAPS is derived from Illinois coal.

The impoundment consists of the Old West Ash Pond (Figure 1-1) including Pond No. 1 (9.3 acres), at the eastern end of the impoundment, which primarily contains bottom ash and slag and Pond No. 3 (16.4 acres), in the central portion of the impoundment, which contains mixed coal ash. The Old West Polishing Pond (4.7 acres) is located at the western end of the impoundment. The berms, which are 15 feet above grade, were constructed from locally occurring sandy soils. Top of ash elevation in all three ponds is lower than the surrounding berms, providing full containment. There are no controls to collect storm water, so all runoff collects in the lowest portion of each pond, where it evaporates or infiltrates through the ash.

During operation, service water was used to sluice fly ash, bottom ash, and low-volume wastes to the impoundment. There was initially a surface water discharge from this impoundment; however, that discharge stopped after the impoundment was reworked in 1989. At the time the impoundment was removed from service in late 1996, there was no surface water discharge and all sluice water exfiltrated via evapotranspiration, seepage through the berms, or leakage through the base of the ponds. The ash is currently dry over most of the surface through most of the year with the exception of: (1) the Old West Polishing Pond, which always contains water; and, (2) within the Old West Ash Pond on the western end of Pond No. 3, where runoff water collects and is ponded most of the year.

1.2.2 Site Hydrogeology

Four principal stratigraphic layers (from top to bottom) encountered at the WAPS and adjacent areas are:

- Fill - coal combustion residuals (CCRs) consisting primarily of fly ash with lesser amounts of bottom ash and slag. This layer also includes the constructed fill berms around the ash ponds, which contain variable admixtures of CCRs and re-worked native silt, clay and sand.
- Alluvial fine grained silts and clays, classified as Cahokia Alluvium.
- Alluvial fine to medium sands.
- Sand and gravel with boulders, deposited by glacial meltwaters and classified as Henry Formation.

The river-laid deposits are classified as Cahokia Alluvium. The Henry Formation sands and gravels make up the upper and lower terraces, and fill the valley beneath the alluvium. A fifth stratigraphic layer (Layer 5) – loamy and sandy diamicton (i.e., till) of the Wedron or Glasford Formation – was encountered at one location (Boring 32) approximately 2,560 feet (½ mile) south of the western end of the impoundment; however, this layer is not significant to the hydrogeology at the impoundment.

The stratigraphy of unlithified materials underlying the Henry Formation is uncertain, but it is assumed based on nearby borings at the power plant, East Ash Pond System, and vicinity that the Henry Formation most likely sits directly on top of bedrock near the WAPS. However, based on the identification of till approximately ½ mile south of the impoundment, it is possible that till of the Wedron or Glasford Formation or an older sand formation, the Sankoty Sand, lies between the Henry Formation and bedrock.

The uppermost bedrock near the Hennepin Power Station, including the West Ash Pond Complex, is the Pennsylvanian Carbondale Formation, which consists of shale with thin limestone, sandstone, and coal beds. Three deeper borings around the perimeter of the East Ash Pond System indicate the presence of shale bedrock between elevations 400 and 410. Water well logs at the power plant indicate shale bedrock at an elevation of roughly 350.

The WAPS lies over both glacial deposits (Henry Formation) and alluvium (Cahokia Alluvium). The Old West Ash Pond, specifically Pond No. 1 lies on top of lower terrace glacial sand and gravel deposits, the eastern portion of Pond No. 3 overlies alluvial sand, while the western portion of Pond No. 3 and the Old West Polishing Pond overlay silty clay alluvial channel fill deposits. More details are presented in the *Hydrogeologic Investigation Report* (NRT, 2017b).

Monitoring wells installed at the West Ash Pond System are shown on Figure 1-2. Groundwater elevation data is available beginning in 1993. The Illinois River is the local and regional groundwater discharge area under normal river stage. River stage is usually lowest during the months of August through October. The river basin experiences annual spring flooding during the months of March, April, May, and sometimes June, while lesser flooding occasionally occurs during autumn. River stage during high precipitation and/or flood events seasonally rises above adjacent groundwater elevations and in low lying areas of the floodplain, particularly within the Donnelley WMA at wells 32, 33, and 34. Horizontal hydraulic gradients from the West Ash Pond Complex to off-site areas ranges from 0.001 foot per foot (ft/ft) during Illinois River flood stage to about 0.005 ft/ft during normal river stage, yielding a groundwater velocity ranging from 0.1 ft/day to 1.1 ft/day.

1.2.3 Groundwater Quality

Groundwater monitoring was performed for selected analytes in 1983, but consistent data collection began in 1996. The monitoring program in 2016 included the full list of inorganic and organic parameters listed in IAC 35 Part 620 Section 410 except for radium 224/226. The most recent data and analysis were submitted in the 2016 Closure Work Plan Annual Report (NRT, 2016).

Parameters that have historically (1996 to 2016) exceeded Class I groundwater standards include boron, iron, manganese and sulfate. Additional parameters that exceeded Class I Standards during the expanded monitoring

performed for the hydrogeologic investigation from June 2013 through March 2014 were arsenic, selenium, nitrate and lead but none of them were attributed to the WAPS.

1.3 CONCEPTUAL MODEL

The WAPS overlays alluvium, and outwash deposits in the Illinois River valley. The principal stratigraphic layers encountered at the WAPS and adjacent areas (from top to bottom) are coal combustion residuals (CCRs) consisting primarily of fly ash with lesser amounts of bottom ash and slag, alluvial fine grained silts and clays classified as Cahokia Alluvium, alluvial fine to medium sands as well as sand and gravel with boulders, deposited by glacial meltwaters which are classified as Henry formation. The primary directions of groundwater flow are north and west, with discharge to the Illinois River – a regional groundwater sink. There are two sources of water: natural recharge within the model domain; and, recharge (percolation) through the impoundment.

Boron was modeled because it is a primary indicator of coal ash leachate, exceeds the Class I standard, is mobile in groundwater, and is more representative of coal ash leachate than sulfate, which may originate from other anthropogenic or natural sources. The monitoring network of boron observations is shown in Figure 1-2. The conceptual model for transport assumes two boron sources: boron that leaches to recharge water during percolation through ash above the water table; and boron that leaches to groundwater as it flows through ash below the water table. Therefore, mass is added to groundwater via vertical recharge through coal ash, and horizontal groundwater flow through coal ash where it lies below the water table. Mass is discharged at the model representation of the Illinois River. The conceptual transport model assumes that boron concentration in leachate does not vary as a function of time, although the volume of leachate decreases over time as a function of pond dewatering and capping. There is no removal of mass from the groundwater system via adsorption or decay.

2 MODEL ESTABLISHMENT

2.1 MODEL BACKGROUND

The 2017 model is an update to, and was derived from, a model developed for the WAPS in 2014 (NRT, 2014). Updates made to this 2017 model include the following:

- The transient calibration period was extended through December 2016 to incorporate all available monitoring data.
- The WAPS ash thickness was re-assessed during a geological investigation conducted by Civil & Environmental Consultants, Inc. (CEC) in March, 2017. Accordingly, the bottom elevations of model Layer 1 at the WAPS location were adjusted to reflect the new data.
- The bottom elevations of model Layer 1 were also adjusted to meet model convergence criteria. One additional layer was inserted beneath Layer 1 to maintain the geological layering in the model.
- The hydraulic conductivities of coal ash, silt and sand were revised to improve calibration results. The updated values of coal ash and silt are close to laboratory conductivity measurements performed by AECOM in December, 2015.
- The river stage was revised to improve calibration results.
- Newly installed monitoring well MW-49 (built in 2016) was added to the monitoring network.
- The recalibrated model was then used to simulate the closure scenario, which was modeled over a period of 200 years, beginning in Year 2017.

2.2 MODEL APPROACH

Three modeling codes were used to model groundwater flow and contaminant transport: 1) percolation through the cap system was modeled using the Hydrologic Evaluation of Landfill Performance (HELP) model. All details regarding closure configurations and HELP model establishment are presented in a separate Hydrostatic Equilibrium Report (NRT, 2017a); 2) groundwater flow was modeled in three dimensions using MODFLOW; and, 3) contaminant transport was modeled in three dimensions using MT3DMS.

A three-dimensional groundwater flow and transport model was established to represent the conceptual flow system described above and then calibrated to match the groundwater monitoring results since 1994. The model was calibrated in four stages:

1. Stage 1: A steady-state flow model was calibrated to approximate head distributions observed while the impoundment was in service, based on median heads observed from 1994 through 1996.

2. Stage 2: The steady state transport model was calibrated to approximate concentrations observed while the impoundment was in service, based on observations from 1994 through 1996.

3. Stage 3: The steady state flow model was converted to a transient flow model and calibrated to match the decreasing heads measured after the impoundment was removed from service. The model period was December 1996 through December 2016 (Transient model stress periods 1 and 2).

4. Stage 4: The transport model was calibrated to approximate boron concentration trends observed since the impoundment was removed from service, using heads from the transient flow calibration model. The model period was December 1996 through December 2016 (Transient model stress periods 1 and 2).

Each subsequent calibration stage required changes to and recalibration of previous stages. The results provide a representative simulation of groundwater flow and transport conditions near the WAPS. The calibrated model was then used as a starting point to predict changes in boron concentrations over a transport period of 200 years under a baseline scenario and a closure configuration:

- Baseline: assumes no action is undertaken.
- Closure Configuration: Old West Polishing Pond is removed. Old West Ash Pond (Pond No. 1 and Pond No. 3) are fully capped by a geomembrane cover, comprised of (from top to bottom) 6-inch vegetative layer, 18-inch protective soil layer, a 0.2-inch geocomposite drainage layer and a 40-mil geomembrane layer.

Two transient stress periods (periods 3 and 4) were added at the end of the transient calibration model to simulate groundwater flow and transport after the capping system was completed (prediction modeling stress periods). The HELP model results (NRT, 2017a) indicated it would take seven years for percolation rates through the cover and CCR material to stabilize (reach equilibrium) after completion of the capping system. Therefore, transient stress period 3 was used for Years 2017 to 2024 to simulate dewatering of the material below the cap and stress period 4 was used to simulate the stabilized percolation rate for the remaining period of 193 years.

2.3 MODEL DESCRIPTION

MODFLOW uses a finite difference approximation to solve a three-dimensional head distribution in a transient, multi-layer, heterogeneous, anisotropic, variable-gradient, variable-thickness, confined or unconfined flow system. User-supplied inputs are hydraulic conductivity, aquifer/layer thickness, recharge, wells and boundary conditions. The program also calculates water balance at wells, rivers and drains.

MODFLOW was developed by the United States Geological Survey (McDonald and Harbaugh, 1988) and has been updated several times since. Major assumptions of the code are: 1) groundwater flow is governed by Darcy's law; 2) the formation behaves as a continuous porous medium; 3) flow is not affected by chemical, temperature, or density gradients; and 4) hydraulic properties are constant within a grid cell. Other assumptions concerning the finite difference equation can be found in McDonald and Harbaugh (1988).

MT3DMS (Zheng and Wang, 1998) is an update of MT3D. It calculates concentration distribution for a single dissolved solute as a function of time and space. Concentration is distributed over a three-dimensional, non-uniform, transient flow field. Solute mass may be input at discrete points (wells, drains, river nodes, constant head cells), or distributed evenly or unevenly over the land surface (recharge).

MT3DMS accounts for advection, dispersion, diffusion, first-order decay and sorption. Sorption can be calculated using linear, Freundlich, or Langmuir isotherms. First-order decay terms may be differentiated for the adsorbed and dissolved phases.

The program uses the standard finite difference method, the particle-tracking-based Eulerian-Lagrangian methods and the higher-order finite-volume TVD method for the solution schemes. The finite difference solution can be prone to numerical dispersion for low-dispersivity transport scenarios, and the particle-tracking method has problems in conserving mass-balance. The TVD solution is not subject to numerical dispersion and conserves mass well, but is computationally intensive. For this modeling, the TVD solution was used.

Major assumptions are: 1) changes in the concentration field do not affect the flow field; 2) changes in the concentration of one solute do not affect the concentration of another solute; 3) chemical and hydraulic properties are constant within a grid cell; and 4) sorption is instantaneous and fully reversible, while decay is not reversible.

2.4 MODEL SETUP

2.4.1 Grid and Boundary Conditions

A six layer, 63 by 79 node grid, was established with variable grid spacing ranging from 100 feet to 200 feet (Figure 2-1). The largest node spacing was upgradient at the lateral model boundary, and the finest node spacing was near the impoundment.

Flow and transport boundaries were the same for all scenarios. The upgradient (east and south) edge of the model was a no-flow boundary (Figure 2-1). The downgradient (north) and lateral (west) boundaries were

either MODFLOW river (Mixed) boundaries (layer 1) or no flow (layers 2-5). Pond No. 1 (Layer 1) was set as no flow condition to ensure the ash remained unsaturated during model simulations. The upper boundary was a time-dependent specified flux (Neumann) boundary, with specified flux rates equal to the recharge rate or the rate of percolation from the impoundment.

The model included two types of transport boundaries (constant concentration and recharge), both in layer 1 (Figure 2-2). Saturated ash areas were represented by constant concentration boundaries. All water passing through these boundaries was assigned a specified concentration representative of ash leachate concentration. The base elevation of nodes representing saturated ash was set to represent depth of ash borings observed in the field. In addition, recharge water in areas overlain by ash was assigned a specified concentration, and the concentration in the underlying node was a result of mixing the recharge flux with the flux passing laterally through the node (unless that node was a saturated ash area, in which case all water passing through was assigned the maximum observed leachate concentration by the constant concentration boundary cell).

2.4.2 Flow Model Input Values and Sensitivity

Flow model input values and results of sensitivity analyses are listed in Table 2-1 and described below.

Layer Top/Bottom

The top of layer 1 was the water table, therefore the elevation of model layer 1 was set at 460 feet, a value higher than the maximum water table elevation (in the impoundment). The top of layers 2 through 6 were set to the base of the overlying layer. The saturated thickness of layer 1 depended on modeled water table elevation. The base of layer 1 at the WAPS was set as the bottom of coal ash elevations and the bottom elevation of the surrounding cells were adjusted to meet the model convergence criteria (Figure 2-3). The base of layer 2 was set at 430 feet and each underlying layer (Layer 3 to Layer 6) was 10 feet thick.

Hydraulic Conductivity

Hydraulic conductivity values (Figure 2-4) were initially derived from field-measured and laboratory tested values and adjusted during calibration. Calibrated values were within observed ranges for the formations present at the site. Vertical anisotropy ratios were set at 2.0 for the sand and gravel and 10 for the silty clay and alluvium. The Kx/Kz ratios represent expected stratification within the formations.

The model had moderate to high sensitivity to the horizontal hydraulic conductivity used over most of the domain. Sensitivity to vertical hydraulic conductivity varied, with the low permeability zones being most sensitive.

Storage

No field data was available defining these terms, so representative values for similar materials were obtained from Smith and Wheatcraft (1993). Sensitivity analysis was not performed on this parameter. The storage coefficient used in the model was 0.01 and the specific yield was 0.30.

Recharge

Recharge rates for the impoundment while in-service and during dewatering were determined during model calibration. Recharge rates for the model domain were adopted from the previous 2014 model and were adjusted during calibration. Recharge zones during the transient calibration period are illustrated in Figure 2-5. Recharge rates after cap completion were set based on the HELP simulations and shown in Figure 2-6. Transient stress period 3 was used for Years 2017 to 2024 to simulate dewatering of the material below the cap. Transient stress period 4 was used to simulate the stabilized percolation rate for the remaining period of 193 years.

Calibrated heads were highly sensitive to changes in recharge rates in zones 5, 6, and 7 of Ash Pond 3 and the outwash gravel (Zone 2). The flow model displayed low to moderate sensitivity to the other recharge zones in the model.

River Parameters

The Illinois River was represented by head-dependent flux nodes that required inputs for river stage, width, bed thickness and bed hydraulic conductivity. The latter three parameters are used to calculate a conductance term for the boundary node. This conductance term was determined by adjusting hydraulic conductivity during model calibration. For simplicity, it was assumed that river stage does not fluctuate and that river gradient is negligible along the reach modeled. In addition, the waterfowl ponds and a small creek that feeds the waterfowl ponds were simulated using MODFLOW river nodes (Figure 2-1).

Sensitivity analysis showed that the model was highly sensitive to river stage, and insensitive to conductance values.

2.4.3 Transport Model Input Values and Sensitivity

Transport model input values are listed in Table 2-2 and described below. The results of sensitivity analyses are also presented in Table 2-2.

Initial Concentration

Initial concentration for the steady state calibration model was set at zero, implying a background concentration of zero, which is reasonable for boron. The final concentrations from the steady state calibration model were used as the initial concentration for the transient calibration model. The prediction model was built by adding two transient stress periods to the transient calibration model as discussed above. The transient calibration model is stress periods 1 and 2, the dewatering phase of the prediction model is stress period 3, and the hydrostatic equilibrium phase of the prediction model is stress period 4.

Source Concentration

Boron source concentrations (from saturated ash) were set during model calibration at values between 7 and 19 mg/L, the range observed in monitoring wells near the impoundment. The setting of source concentration is consistent with the 2014 model. As mentioned in Section 2.4.1, Pond No. 1 (Layer 1) was set as no flow condition instead of a constant concentration boundary to simulate unsaturated ash observed at Pond No. 1. Source concentration originating from Pond No. 1 (leachate percolating through the unsaturated ash) was simulated by applying concentration to the recharge zone above the no flow cells, which was then applied to the highest active layer (Layer 2). Using a combination of no flow cells and recharge inputs for simulating Pond No. 1 ensures the only source concentration entering the model from Pond No. 1 is in the form of leachate through the base of the unsaturated ash.

Since clean closure will be applied to the Old West Polishing pond, the source concentration at the Old West Polishing pond was set as zero during stress periods 3 and 4 (Figure 2-7).

Boron source concentrations from recharge were also determined during model calibration (Table 2-2) and remained the same during the prediction stress periods 3 and 4. The recharge rates were reduced as discussed above.

Effective Porosity

Effective porosity values were based on ranges provided by Mercer and Waddell (1993). Predicted concentrations at some wells distant from the impoundment (wells 26, 30, 31) had moderate sensitivity to this parameter (Table 2-2).

Dispersivity

Dispersivity was set during model calibration. Transverse and vertical dispersion were estimated according to ratios developed by Gelhar et al. (1985). Calibrated concentrations at some wells distant from the impoundment (wells 26, 30, 31, 36) were highly sensitive to the longitudinal dispersivity value and to the vertical dispersivity multiplier, while calibrated concentrations were not sensitive to the transverse dispersivity multiplier.

Retardation

Retardation was calculated by the model based on the distribution coefficient (K_d), which was set during calibration. Concentration match was best when K_d was set at zero for the sand and gravel units, and at 1.0 mL/g in the silty units (channel-fill deposit and alluvium) (Figure 2-8). The K_d value of 1.0 mL/g resulted in a retardation factor of 9.0 in the silt units. Calibrated concentrations at wells distant from the impoundment (wells 26, 27, 30, 31, 36) were highly sensitive to the K_d value modeled for the sand units, while the model exhibited low sensitivity to the range of K_d values tested for the silt units.

Diffusion

Diffusion was also set to 0 for the entire model domain.

3 MODEL RESULTS

3.1 Flow and Transport Model Assumptions and Limitations

Simplifying assumptions are necessary when numerically representing the natural environment in a groundwater flow and transport model. Outside of assumptions inherent to the codes used to develop the model, several simplifying assumptions were made, including:

- Leachate instantaneously migrates to groundwater (e.g., rapid migration through the unsaturated zone).
- Fluctuations in river stage are short in duration and do not affect groundwater flow and transport.
- Recharge rate outside the impoundment is constant over time.
- Source concentrations remain constant over time.
- Boron minimally adsorbs and does not decay, and mixing and dispersion are the primary attenuation mechanisms.
- Cap construction has an instantaneous effect on recharge and percolation because it is constructed over a brief period relative to the length of the model simulation.

The model is limited by the data used for calibration, which adequately define the local groundwater flow system and the source and extent of the plume. These data, collected from 1994 through 2016, are from points near the WAPC. Model predictions of transport distant from the impoundment will not be as reliable as predictions of transport near the impoundment, and the reliability of model predictions decreases with increasing time because changes to the system may occur that the model does not account for.

3.2 Calibration Flow and Transport Model Results

Results of the MODFLOW/MT3DMS modeling are presented below. A CD containing the model files is attached to this report (Appendix A).

Figure 3-1 compares modeled versus observed steady-state heads for the period while the impoundment was in service. Figure 3-2 compares modeled versus observed heads for the period 1994 through 2016 at Wells 21, 22, 23, 24, 25/26, 27, 30, 31, 32, 33, 34, 35, 36, L1, L4 and 49. Modeled heads at all monitoring wells fall within the range of observed values. The modeled and observed heads demonstrate a linear trend that falls just above the ideal 1 to 1 line, which indicates the calibrated groundwater elevations are slightly higher than observed but adequately represent the calibration data across the range of observed values. The graph of observed values and calibration residuals indicates most of the residuals are negative, which also suggests the steady state model results are biased a little high. However, the data have a good degree of scatter, indicating the model is not biased across the range of elevations observed. The relative standard deviation, given as a percentage of standard deviation to data mean, was determined to be 7.1%, which is within the acceptable target of less than 10%. This statistical result is strong evidence of the steady state model's ability to simulate flow within the range of groundwater elevations observed. Modeled heads in the transient model follow observed trends observed from 1997 through 2016, and successfully capture the hydraulic head drops after the impoundments were removed from service (Figure 3-2). The consistency between observable data and modeling results indicate that this model provides a reasonable simulation of the effects of the WAPS on groundwater flow.

The simulated boron concentration trends are compared to observed data in Figure 3-3. The simulated boron concentrations reasonably match the observed concentrations. For example, the transport model exhibits a successful simulation of the short-term concentration increase at Well 24 between 1998 and 2000, and captures the decreasing concentration trends at wells 22, 24, 25/26, 27, 30 and 31 after removing the impoundment from service (well locations are shown on Figure 1-2). It also predicts no decrease in concentration relative to initial conditions at wells 21 and 23. The model made conservative simulations of boron concentration at Well 24 after Year 2009 and at Well 49, which was installed in 2015 and has limited data. The agreement between modeled

and predicted concentrations demonstrates the capability of the transport model for the prediction of contaminant transport in groundwater at the site.

3.3 Model Prediction

As stated in the previous sections, the prediction model was extended 200 years following the cap completion (2017 to 2217) to evaluate boron concentrations in groundwater under a baseline (no action) scenario and the closure configuration. The predicted hydraulic heads under the two conditions are compared in Figure 3-4. The predicted boron concentrations under the two conditions are compared in Figure 3-5.

3.3.1 Baseline

Under the baseline scenario, it was assumed that no action was taken to cover or remove existing ash. As shown in Figures 3-4 and 3-5, both hydraulic head and boron concentrations are predicted to remain stable except at Well 27, in which the boron concentration would decrease even when no action was applied. As shown in Figure 1-2, Well 27 is located further downgradient from the pond. The continuous decrease of boron concentration at this location under the baseline scenario is its response to the pond removal from service.

Figure 3-6 depicts the predicted boron plume where it exceeds the Illinois Class I groundwater protection standard (2 mg/L) 50 years after cap completion. The boron plume is predicted to extend north beneath the Illinois River. As illustrated in Figure 3-5, the boron concentrations at wells become asymptotic; no further reduction is expected with time and most wells with boron concentrations that exceed the standard will remain above the standard after 200 years.

3.3.2 Capping Scenario

Under the capping scenario, it was assumed that the Old West Polishing Pond would be excavated and the remaining WAPS (Old West Ash Pond, including Pond No. 1 and Pond No. 3) would be capped in place with a geosynthetic cover that was expected to yield a percolation rate as low as 0.002 inch/yr (NRT, 2017a).

Comparing the baseline to the capping option, significant reduction in boron concentrations is predicted in monitoring wells (Figure 3-5). All wells would reach the standard in 50 years except wells 21 and 23, the concentrations of which will eventually decrease to meet the criterion within the 200-year simulation. Slight drops in hydraulic heads are observed after the cap is in place, which is due to the infiltration decrease.

As shown in Figure 3-6 (50-year plume), the footprint of the plume under the capping scenario is significantly reduced and the highest boron concentrations are focused within the pond footprint. Groundwater impacts beneath the eastern portion of the pond are attenuated by 50 years. The remaining impacts are focused around the capped and saturated ash along with the lower permeability silty/clay material beneath the western portion of the pond. This lower permeability material results in slower release/attenuation of the impacts as compared to other portions of the site which are underlain by higher permeability sands. Figure 3-7 shows the plume configuration in Layer 4, where boron is slowly attenuated. The north-south shape of the western portion of the boron plume is consistent with the north-south hydraulic conductivity distribution shown in layers 4 through 6 on Figure 2-4.

After 200 years (year 2217), as shown in Figure 3-8, the footprint of exceedances (boron concentrations greater than 2 mg/L) will be limited to the property except for a few isolated areas where the western extent of the plume lingers in association with the silty material. The modeling results show that the proposed closure configuration effectively consolidates groundwater impacts to the footprint of the capped impoundment.

4 SUMMARY

A 3-dimensional groundwater flow and transport model was established to evaluate the effectiveness of the proposed closure plan on the WAPS at the Hennepin Power Station. The proposed closure configuration includes clean closure of the Old West Polishing Pond and capping the remaining impoundments in place with a geosynthetic cover, which consists of a 6-inch surface soil layer, a 18-inch soil layer, a geocomposite drainage layer and a geosynthetic layer. The model was developed based on a previous 2014 model with incorporation of new field and laboratory measurements and was recalibrated to fit additional monitoring data. In summary, the results of the modeling are:

- The consistency between modeling results and the observable data collected from 1994 through 2016 exhibits a successful calibration of the updated model, demonstrating the model's capability for the prediction of hydraulic flow and contaminant transport in groundwater at the site.
- When no action is taken, groundwater impacts will not be contained within the property and groundwater protection standards will not be met for boron. Boron concentrations become asymptotic after approximately 50 years (Year 2067) and no further reduction is expected with time.
- Under the proposed closure scenario, significant reduction in groundwater impacts are expected. Boron concentrations in most wells will meet the groundwater protection standards in 50 years upon cap completion (Year 2067) and all wells will meet the standards within 200 years (Year 2217).
- At 50 years after cap completion, the remaining impacts outside the footprint of the capped impoundment appear to be attributed to lower permeability silty/clay material beneath the western portion of the pond. After 200 years (year 2217), groundwater impacts are nearly removed and only isolated areas of impacts remain (also associated with the silty/clay materials). The proposed closure configuration effectively consolidates groundwater impacts to the footprint of the capped impoundment.

APPENDIX C
MATERIAL QUANTITY, LABOR, AND MILEAGE ESTIMATES FOR ALTERNATIVE 2 REMEDY

RAMBOLL

DYNEGY MIDWEST GENERATION, LLC - HENNEPIN POWER PLANT
CORRECTIVE ACTION ALTERNATIVES ANALYSIS SUPPORTING INFORMATION REPORT (CAAA-SIR)
ALTERNATIVE 2 - SOURCE CONTROL WITH CONTINUOUS CONTAINMENT SYSTEM[1]

ITEM NO.	ENGINEERING, PRE-CONSTRUCTION, AND CONSTRUCTION SUPPORT TASKS	Units	Quantity	Crew	Daily Output	Labor Hours	Equipment Hours	Notes
1	Engineering Support and CQA During Construction	LS	1	Eng	12	6,240	2,080	Assumed labor and equipment hours based on Ramboll project experience.
	ENGINEERING, PRE-CONSTRUCTION, AND CONSTRUCTION SUPPORT ESTIMATED SUBTOTAL					**6,240**	**2,080**	
ITEM NO.	**SITE PREPARATION**	**Units**	**Quantity**	**Crew**	**Daily Output**	**Labor Hours**	**Equipment Hours**	**Notes**
2	Staging/Laydown Area Preparation	-	-	-	-	1,295	390	Assumes the general work area associated with the cutoff wall will need to be graded and built-up in order to make way for construction equipment needed for the install.
	Subsurface Stabilization Nonwoven Geotextile	SY	19,400	2 Clab	2500	124	0	313219161550: Geosynthetic soil stabilization, geotextile fabric, non-woven, 120 lb tensile strength includes scarifying and compaction. This assumes stabilization of access roads, staging area, and material handling system.
	Construct Staging/Laydown Areas	SY	15,000	B14	615	1,171	390	015523500100: Temporary, roads, gravel fill, 8" gravel depth, excluding surfacing. Assumes 3-acre staging/laydown area.
3	Construction Soil Erosion & Sediment Controls	-	-	-	-	774	258	Assumes soil erosion and sediment controls will be implemented only during the cutoff wall construction.
	Silt Fence	LF	20,800	B62	650	768	256	312514161000: Synthetic erosion control, silt fence, install and remove, 3' high. Assumes silt fence is installed down both sides of the cutoff wall alignment (5,200 ft total per side) and the silt fence is replaced once during cutoff wall construction. (20,800 ft total)
	Straw Wattles	LF	250	A2	1000	6	2	312514160705: Sediment Log, Filter Sock, 9". Assume straw wattles are needed along perimeter of cutoff wall and staging/laydown area at an occurrence of 1 every 50 feet. Replaced straw wattles once.
4	Construction Facilities	MO - in use	-	-	-	24	-	Assumes office trailer, storage boxes, and portable toilets are required during the construction phase of the alternative.
	Office Trailer	MO - in use	24	B66	-	8	-	015213200350: Office trailer, furnished, no hookups, 32' x 8'. Assume quantity of one (1). Duration is assumed to be 24 months for construction with winter contingency.
	Storage Trailers	MO - in use	24	B66	-	8	-	015213201350: Storage boxes, 40' x 8'. Assume quantity of three (3). Duration is assumed to be 24 months for construction with winter contingency.
	Portable Toilet	MO - in use	24	B66	-	8	-	015433406410: Toilet, portable chemical. Assume quantity of four (4). Duration is assumed to be 24 months for construction with winter contingency.
5	Temporary Contact Stormwater Management System					2,731	710	System to transfer CCR-contact stormwater to the existing onsite settling ponds for treatment prior to discharge
	Install Sump	EA	6	SI	4	24	12	Crew and Daily Output based on experience. Assumed one sump every 5 acres.
	Install 8" HDPE Conveyance Pipe	LF	11,200	B22A	320	1,400	280	331413350300: Water supply distribution piping, piping HDPE, butt fusion joints, 40' lengths, 8" diameter, SDR 21. Includes labor, materials, and machine for installation and welding of HDPE pipe for conveying extracted water from sumps to EAP.
	Install Transfer Pump and Controller	EA	1	B6	1	52	0	Installation of transfer pump and pump controller to convey water from sumps to discharge outfall based on Ramboll project experience. Assumes inclusion of housing structure. Assume 2 days for installation.
	Install Equilibrium Tank	EA	2	B6	1	180	60	Installation of equalization tank at each trench and associated site preparation and instrumentation. Assumes 2 days for installation.
	Pipe Abandonment	LF	11,200	B6	250	1,075	358	024113380090: Selective demolition of 8" pipe.
6	Cutoff Wall Alignment Preparation Work Pad	-	-	-	-	2,263	754	Construct a temporary gravel work pad along entire cutoff wall alignment.
	Install Crushed Gravel Road (18" Thick) - Right of Way	SY	29,000	B14	615	2,263	754	015523500100: Temporary, roads, gravel fill, 8" gravel depth, excluding surfacing. Spanning 5,200-feet long and 50-feet wide.
	SITE PREPARATION ESTIMATED SUBTOTAL					**7,088**	**2,113**	
ITEM NO.	**CUTOFF WALL CONSTRUCTION**	**Units**	**Quantity**	**Crew**	**Daily Output**	**Labor Hours**	**Equipment Hours**	**Notes**
7	Temporary Final Cover Removal		-	-	-	482	140	Remove the final cover including cover soil and geosynthetics along the cutoff wall alignment to minimize damage to the final cover system over WAPS.
	Cover Removal	CY	2,300	B10X	575	48	32	312316465570: Excavating, bulk, dozer, open site, bank measure, common earth, 460 HP dozer, 300' haul Assumed 2 feet of thickness over 7 acres, is removed and stockpiled at coal yard.
	Geosynthetic Layers Removal	SF	305,000	B63B	22500	434	108	310519531200: Pond and reservoir liners, membrane lining systems HDPE, 100,000 S.F. or more, 60 mil thick, per S.F. Assumed removal of 7 acres. Also assumed removed geomembranes will be disposed of beneath the repaired final cover system to minimize off-site hauling/disposal.
8	Installation of Cutoff Wall	SF	504,400	-	-	10,761	2,690	Spoils to be temporarily placed in Hennepin Coal Yard and ultimately be placed in WAPS beneath the final cover system. Assumes 5,200-foot wall alignment, 3-foot wall width, and 97-foot wall depth. Assumes 5 feet thick layer that consists of boulders that require the use of hydromill. 312316420550: Excavating, bulk bank measure, 1 C.Y. capacity = 35 C.Y./hour, clamshell, excluding truck loading. This line item was included to quantify labor and equipment hours.
	Contruction Through Layer with Ash, Sand, Silt, and Clay - Heavy Equipment	SF	478,400	B12H	1500	5,103	2,551	Excavation of 92 feet of materials that do not require a hydromill.
	Contruction Through Layer with Ash, Sand, Silt, and Clay - Labor	SF	478,400	2 Clab	1500	5,103	0	Additional laborers to assist excavation
	Contruction Through Layer with Ash, Sand, Silt, and Clay - Heavy Equipment	SF	26,000	B12H	1500	277	139	Excavation of 5-foot layer with boulders that require the use of a hydromill. Assumed a total of 5 feet of the entire cutoff wall may require advancement through boulders or other obstructions.
	Contruction Through Layer with Ash, Sand, Silt, and Clay - Labor	SF	26,000	2 Clab	1500	277	0	Additional laborers to assist excavation
9	Spoils Management	CY - Loose	57,000	-	-	2,846	2,255	Quantity based on surface to surface calculation. Spoils assumed to be temporarily staged in Hennepin Coal Yard Area and then moved to EAP for use as contouring fill.
	Loading	CY - as excavated	114,000	B14B	5000	274	182	312316435320: Excavating, large volume projects; excavation with truck loading; excavator, 6 C.Y. bucket, 100% fill factor (assume 10% fluff factor from ground to excavated).
	Double Hauling and Placement at Coal Yard area	CY - as excavated	114,000	B34G	850	1,073	1,073	312323206170: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 1 mile. Daily output extrapolated down to 10 min wait.
	Spreading/Drying Moisture Conditioning	CY - as excavated	57,000	B10B	1000	684	456	312323170020: Spread dumped material, no compaction, by dozer. Daily output edited to match excavation based on experience. Quantity assumes 50% of volume requires moisture conditioning.
	Spreading Lifts	CY - as excavated	57,000	B10B	1000	684	456	312323170020: Spread dumped material, no compaction, by dozer. Daily output edited to match excavation based on experience.

	Compaction of Material	CY - in place	57,000	B10G	5200	132	88	312323235680: Compaction; Riding, sheepsfoot or wobbly wheel roller, 12" lifts, 2 passes. Assuming material to be compacted will be fine and not coarse.
10	Geotechnical Monitoring	LS	-			1,176	-	Geotechnical monitoring of embankment stability during wall construction
	Installation Fee	LS	1	GM	-	600	-	Assumes installation of inclinometers, survey prisms, and settlement monitoring devices along the WAPS dikes. Assumes a 4-person crew installs the monitoring system over a period of 3 weeks. Based on Ramboll experience
	Monthly O&M Fee	MO	24	Eng	-	576	-	Assumes crew to make two-day visits for monthly calibration, etc for duration of construction.
11	Contact Water Storm Water Management					236	11	Contact storm water will be collected from the sumps and pumped to the Leachate Pond or Secondary Settling Pond near EAP.
	Field Maintenance (O&M)	Event	104	OM	-	208	0	Assumes weekly maintenance visits on pumps and conduits during construction. Each visit assumes 2 staff for 2 days to check, clean, and service all mechanical parts. Assumes 24 months of contruction.
	Generator Charges	Ea	1	R3	1	28	11	263213160300. Gasoline, 3 phase 4 wire, 277/480 V, 11.5 kW generator
	CUTOFF WALL CONSTRUCTION					**15,501**	**5,097**	
ITEM NO.	**SITE RESTORATION**	**Units**	**Quantity**	**Crew**	**Daily Output**	**Labor Hours**	**Equipment Hours**	**Notes**
12	Replacement of Cover Soils/Vegetation	-	-	-	-	118	99	Assumes restoration of chain link fence along property boundary and restoration of grade surface following cutoff wall installation
	Loading and Spreading Stockpiled Cover Material	CY	2,300	B10B	1000	28	18	312323170011: Fill, dumped material, spread, by dozer, excludes compaction Assumed 2 feet of thickness over 7 acres, returned from stockpile staged at coal yard
	Grading	Ea	1	B62	2	16	5	312213200130: Rough grading sites, 1,100-3,000 S.F., skid steer & labor
	Lime	MSF	455	B66	700	5	5	329113234250: Soil preparation, structural soil mixing, spread soil conditioners, ground limestone, 1#/S.Y., tractor spreader. Assume soils possibly being void of nutrients.
	Fertilizer	MSF	455	B66	700	5	5	329113234150: Soil preparation, structural soil mixing, spread soil conditioners, fertilizer, 0.2#/S.Y., tractor spreader. Assume soils possibly being void of nutrients.
	Grassland Mix	MSF	350	B66	52	54	54	329219142300: Seeding athletic fields, seeding fescue, tall, 5.5 lb. per M.S.F., tractor spreader. Quantity all disturbed areas minus wetland area, pollinator area, and 15-acre pond in consolidated area.
	Mulch	MSF	350	B65	530	11	11	329113160350: Mulching, Hay, 1" deep, power mulcher, large.
13	Replacement of Liner Materials	-	-	-	-	441	0	Assumes replacing damaged liners along the cutoff wall alignment

NOTES:

1. Alternative 2: Source Control with continous containment system is estimated to take approximately 33 years to achieve groundwater protection standards (GWPS-35 I.A.C Section 845.600) at a majority of perimeter wells associated with the West Ash Pond System (WAPS). The monitoring period has been capped at 30 years total, plus 3 additional years of compliance monitoring.
2. RS Means refers to the 2023 online edition of RS Means Heavy Construction.
3. See crew tab (Alt 2 - Crew) for assumptions regarding crew size, total labor hours and required construction equipment, as needed, for each task.
4. See mileage tab (Alt 2 - Mileage) for assumptions regarding total mileage for tasks outlined in this alternative.

ACRONYMS:

AC = Acre
CY = Cubic Yard
  Bank: Material in natural compacted state
  Loose: Material swelled when removed from compacted state
EAP = East Ash Pond
EA = Each
WAPS = West Ash Pond System
GWPS = groundwater protection standards
LF = Linear Foot
LS = Lump Sum
MSF = square feet divided by 1000
MO = Month

1. INTRODUCTION

1.1 Overview

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has developed this assessment of groundwater corrective measures on behalf of the Hennepin Power Plant (HPP), owned and operated by Dynegy Midwest Generation, LLC (DMG), to assist in the compliance with the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845: Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments. This assessment applies specifically to the coal combustion residuals (CCR) surface impoundments (SI) referred to as the West Ash Pond System (WAPS), also referred to as the Old West Ash Pond (OWAP [Illinois Environmental Protection Agency [IEPA] identification [ID] number (No.) W1550100002-01]) and Old West Polishing Pond (OWPP, [IEPA ID No. W1550100002-03]), and CCR Unit ID No. 804, and National Inventory of Dams (NID) No. IL50698. This report addresses content requirements specific to 35 I.A.C. § 845.660 (Assessment of Corrective Measures) for exceedances of arsenic, boron, sulfate, lithium, and total dissolved solids (TDS) at the WAPS.

1.2 Source Control and Residual Plume Management

DMG completed significant source control and residual plume management efforts in 2020 as part of final closure of the WAPS. The final closure was performed in accordance with the Closure and Post-Closure Care Plan (Closure Plan; Geosyntec Consultants, Inc. [Geosyntec], 2017) that was developed in accordance with Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257 and submitted to IEPA for review. IEPA approved the Closure Plan and found "*…the closure and post-closure care plan…to be an adequate corrective action*" (IEPA, 2018). The final closure was addressed in accordance with the IEPA Water Pollution Control permit 2020-EA-65026-1.

The WAPS closure construction included a hybrid consolidate-and-cap approach comprised of closure-by-removal (CBR) of the OWPP and closure-in-place (CIP) of the OWAP. This was accomplished by removing impounded water from within the OWAP and OWPP, excavating CCR and approximately one foot of soil below the CCR, from the OWPP and placing it into the OWAP, and constructing an alternate soil and geosynthetic cover system over the OWAP, in accordance with 40 C.F.R. § 257.102. These source control activities will serve as the primary groundwater corrective measure at the WAPS. The potentially feasible corrective measures presented herein are intended to be supplementary to the primary source control and are intended to serve as management measures to address any residual plumes that remain after completion of source control.

Attachment A includes summary figures (from the final closure plan) showing the final IEPA approved source control and primary corrective action.

1.3 Adaptive Site Management

Adaptive site management strategies will be employed as an integral part of ongoing corrective action at the WAPS. The adaptive site management approach will allow timely incorporation of new site information over the post-closure life cycle of the WAPS to ensure the achievement of the groundwater protection standards (GWPS). The adaptive site management approach is proposed to expedite progress toward meeting the GWPS while acknowledging uncertainties, such as the persistence of current groundwater flow directions and flux quantities and potential related changes in geochemical conditions. A structured decision-making process and explicitly

planned iterations between the implemented corrective measures and monitoring results will ensure that remediation is occurring. System performance and the condition of the residual plume will be monitored as the corrective measure(s) selected through the I.A.C. § 845.710 Corrective Action Plan (CAP) process are implemented to supplement the source control measures described above. If the groundwater concentrations do not decrease consistent with the modeling prediction, the adaptive site management approach will facilitate timely modifications or enhancements to the corrective measure(s), as needed in accordance with 35 I.A.C. §845.680(b). This approach will be employed to provide continuous improvement to the WAPS groundwater remediation in response to new site information and/or the performance of the selected corrective measure(s).

The planned adaptive site management strategies are generally consistent with National Research Council, Interstate Technology & Regulatory Council (ITRC) and United States Environmental Protection Agency (USEPA) methodologies developed to address sites with long remediation times and high levels of uncertainty regarding the remedial actions necessary to achieve final and protective remediation goals (USEPA, 2022). The elements of the proposed adaptive site management strategy at the WAPS will be responsive to the changing conditions associated with pond closure and performance of the selected corrective measure(s) and will include the following:

1. Implementing the groundwater corrective measure(s) selected as part of the CAP for the current conditions at the WAPS. The selected corrective measures may include a combination of the technologies presented in this Corrective Measures Assessment (CMA).
2. Establishing both the absolute remedial objective and functional (interim) goals to monitor progress toward the remedial objective. Achieving the GWPS for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary is the remedial objective for the WAPS. Specific functional goals will be developed as part of the CAP process. The functional goals will be measurable thresholds for future action and may include short-term or technology-specific objectives and triggers. Functional goals may vary for different locations, CCR constituents or other site-specific considerations (ITRC, 2017) and will serve as benchmarks for comparison to ongoing groundwater monitoring at the WAPS.
3. Ongoing groundwater monitoring at the WAPS will continue throughout at least the post-closure care period. Post-closure monitoring will continue for a period of at least 30 years, in accordance I.A.C. § 845.780(c), or until GWPS have been met for at least 3 years, whichever is longer. A comprehensive groundwater monitoring plan (GMP) will be developed as part of the CAP process in accordance with 35 I.A.C. § 845.670 and 35 I.A.C. § 845.220(c)(4). The GMP will include the functional goals and proposed action levels.
4. Groundwater monitoring information will be used to guide decisions regarding whether progress toward the remedial goal is advancing as expected and/or whether additional actions may be needed to achieve the remedial objective, in conjunction with IEPA, as required by 35 I.A.C. § 845.680(b).

2. SITE INFORMATION

The HPP is located in the northwest quarter of Section 26, Township 33 North, Range 2 West, Putnam County, Illinois and approximately 3 miles north-northeast of the Village of Hennepin. The WAPS is located west of the power plant and situated in an area that is a mixture of agricultural and undeveloped land use (**Figure 2-1**). The WAPS is a closed CCR SI consisting of two closed, unlined CCR sub-units including the OWAP (IEPA Unit ID W1550100002-01) and the OWPP (IEPA Unit ID W1550100002-03). The two sub-units formerly comprised the WAPS and were surrounded by a continuous earthen embankment. Prior to closure, the sub-units were divided utilizing an internal splitter dike to support plant operations, where CCR was deposited within the OWAP and the OWPP was utilized as a polishing pond prior to discharging process water to the Illinois River via a National Pollutant Discharge Elimination System (NPDES) outfall. As part of closure, the OWPP, all CCR within the OWPP, and the OWPP perimeter dikes were removed and placed within the WAPS. The pre-closure surface area of the WAPS was approximately 35 acres. The current surface area of the OWAP final cover area is approximately 29 acres (**Figure 2-2**). The Illinois River is connected to the post-closure OWPP by a culvert, allowing for the water level in the OWPP to be similar to the Illinois River. The OWPP functions as post-closure wildlife habitat.

The Closure Plan was submitted to IEPA in 2017 (Geosyntec, 2017). The Closure Plan was approved by IEPA in a letter dated June 19, 2018. The approved Closure Plan summarized the planned closure of the WAPS, which included dewatering the CCR, mechanical excavation of material from the OWPP for use as structural fill in the WAPS, grading within the WAPS, constructing an alternative cover system consisting of geomembrane and vegetated cover soils in direct contract with the graded CCR, and establishment of a vegetative cover. Closure construction was completed by November 17, 2020 (DMG, 2020a; DMG 2020b).

2.1 Conceptual Site Model

Significant site investigation has been completed at the HPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the WAPS has been well characterized and detailed in the Hydrogeologic Site Characterization Report (HCR; Natural Resource Technology, an OBG Company [NRT/OBG], 2017c). The conceptual site model (CSM) is presented below.

There are three dominant geomorphic features in the immediate vicinity of the HPP: an upper river terrace at an elevation of about 500 to 550 feet[1], a lower river terrace at an elevation of about 450 to 460 feet, and the current river valley filled with alluvium to an elevation of about 445 feet. The HPP and the eastern portion of the WAPS are on the lower terrace. The western portion of the WAPS overlies alluvium.

The hydrogeological assessment identified that the stratigraphy within and immediately surrounding the WAPS consists of fill, unlithified river alluvium, and Pleistocene-age glacial outwash deposits overlying Pennsylvanian-age shale bedrock. Where undisturbed or partially excavated, the native surficial soil at the site is poorly drained, moderately permeable silty clay loam formed as alluvium in floodplains.

[1] All elevations in this report are refenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

The Site is characterized by two hydrostratigraphic units:

- **Uppermost Aquifer (UA)**: Includes the unlithified natural geologic materials of the Cahokia Alluvium and Henry Formation extending from the upper saturated zone to the bedrock. The UA contains variable amounts of cobbles and boulders within a sand and gravel matrix. Both the prevalence and size of the cobbles and boulders increase with depth.
- **Bedrock Confining Unit**: Comprised of shales with thin limestone, sandstone, and coal beds. This bedrock confining unit is encountered at elevations ranging from 399.2 to 410.2 feet.

The direction of groundwater flow and hydraulic gradient within the UA varies with the elevation of the Illinois River. During normal river stage the direction of groundwater flow is most often toward the river, but comparison of groundwater and river elevation data indicate reversals in this flow direction during times of high river elevations. The relative duration of these events is short, which leads to the determination of a predominant groundwater flow direction toward the river. Groundwater elevations and contours for the May 2023 monitoring event (Event 1 [E001]) are presented in **Figure 2-3**.

2.2 Groundwater Quality

Groundwater monitoring in accordance with the GMP and sampling methodologies provided in the operating permit application for the WAPS began in the second quarter of 2023. The 35 I.A.C § 845 groundwater monitoring system is displayed on **Figure 2-4** and consists of 11 wells screened in the UA (two background and nine compliance) and one temporary water level only surface water staff gauge. The groundwater samples collected from the 11 wells are used to monitor and evaluate groundwater quality and demonstrate compliance with the groundwater quality standards listed in 35 I.A.C. § 845.600(a). The proposed monitoring wells yield groundwater samples that represent the quality of downgradient groundwater at the CCR boundary (as required by 35 I.A.C. § 845.630(a)(2)).

The E001 sampling event was completed on June 1, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), statistically derived values were compared with the GWPSs summarized in 35 I.A.C. § 845.600 to determine exceedances of the GWPS (Ramboll, 2023a). The statistical determination identified the following GWPS exceedances at compliance groundwater monitoring wells:

- Arsenic at wells 21R and 51
- Boron at wells 21R, 22, 23, and 35
- Cadmium at well 22
- Sulfate at wells 23 and 35
- Lithium at well 22

Subsequent compliance sampling events for Quarter 3 and Quarter 4 2023 (Event 2 [E002] and Event 3 [E003]) were completed in August and November 2023 and groundwater samples were evaluated for exceedances of the GWPS as described in 35 I.A.C. § 845.600 (Ramboll, 2024a; Ramboll, 2024b). The following additional exceedances were identified during the E002 and E003 monitoring events:

- Lithium at well 22
- TDS as well 35

Pursuant to 35 I.A.C. § 845.650(e), an alternative source demonstration (ASD) was prepared and submitted to IEPA that presented evidence demonstrating that sources other than the WAPS were the cause of the cadmium GWPS exceedance listed above (Ramboll, 2023b). The IEPA concurred with the ASD; therefore, arsenic, boron, sulfate, lithium, and TDS exceedances are addressed in this CMA, in accordance with 35 I.A.C. § 845.660.

3. CORRECTIVE MEASURES ASSESSMENT METHODOLOGY

This section describes the CMA methodology initiated in response to the identification of exceedances of the GWPS for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary of the WAPS during the E001 groundwater monitoring event (Ramboll, 2023a). The CMA was initiated on December 10, within 90 days after the detection of exceedance(s) of GWPS. Under 35 I.A.C. § 845, owners and operators of existing CCR SIs must initiate the assessment of corrective measures in accordance with 35 I.A.C. § 845.660 if one or more constituents are detected, and confirmed by an immediate resample, to be in exceedance of a GWPS in 35 I.A.C. § 845.600, and the owner or operator has not demonstrated that: a source other than the CCR SI caused the exceedance, or; that the exceedance of the GWPS resulted from error in sampling, analysis, statistical evaluation, natural variation in groundwater quality or a change in the potentiometric surface and groundwater flow direction (an ASD).

The CMA is the first step in developing a long-term CAP to address the GWPS exceedances at CCR SIs. The process provides a systematic, rational method for evaluating potential corrective measures by first identifying potentially applicable technologies and evaluating them using qualitative information to eliminate from consideration infeasible or otherwise unacceptable remedial technologies (*i.e.,* the 35 I.A.C. § 845.660 CMA). The remaining technologies will be evaluated individually, or assembled into combined alternatives, and further evaluated under the 35 I.A.C. § 845.670 CAP process. The final outcome of the process will be to select an appropriate and protective corrective action(s) for the WAPS.

This CMA identified applicable corrective measure technologies and evaluated them for viability, given the site-specific conditions and considerations at the WAPS, by addressing the following 35 I.A.C § 845.660 evaluation criteria:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the CAP; and
- Institutional requirements, such as State or local permit requirements or other environmental or public health requirements that may substantially affect implementation of the CAP.

The evaluation included qualitative and/or semi-quantitative screening of the potential corrective measures (technologies) relative to their general performance, reliability, and ease of implementation characteristics and their potential impacts, timeframes, and institutional requirements to assess the viability of each technology to address the GWPS exceedances at the WAPS. This approach provided a reasoned set of corrective measures that could be used, either individually or in combination, to supplement the source control measures described in **Section 1.2** and achieve GWPSs in the most effective and protective manner. This set of corrective measures will be further evaluated in the Corrective Action Alternatives Analysis (CAAA).

4. DESCRIPTION OF POTENTIAL CORRECTIVE TECHNOLOGIES

The potential groundwater corrective measures summarized below are applicable to the WAPS and were included in the CMA development and analysis. Site-specific considerations regarding the WAPS provided in **Section 2** were used to evaluate potential groundwater corrective measures. Each of the corrective measures evaluated may be capable of satisfying the requirements and objectives, listed in **Section 3**, to varying degrees of effectiveness. The corrective measure review process was intended to yield a set of applicable corrective measures that could be used to supplement the completed source control activities described in **Section 1.2** (CBR of the OWPP and CIP with a geosynthetic cap at the OWAP). The completed source control has significantly reduced infiltration rates relative to pre-closure conditions. Ongoing monitoring will be an integral part of all corrective measures to verify and document the remedial process. The corrective measures ultimately advanced to the CAAA and selected in the CAP will be used to enhance the effectiveness of the source control and may be used independently or may be combined into specific remedial alternatives to leverage the advantages of multiple corrective measures to attain GWPSs.

Source control measures were completed in 2020 for the WAPS, as described in **Section 1.2**; all of the evaluated corrective technologies are proposed to be supplemental and complementary to source control activities. The following potential corrective measures, commonly used to mitigate groundwater impacts, were considered as a part of the CMA process:

- Source Control with Groundwater Polishing;
- Source Control with In-Situ Stabilization (ISS);
- Source Control with Groundwater Extraction (groundwater pumping wells or collection trenches);
- Source Control with a Cutoff Wall; and
- Source Control with In-Situ Chemical Treatment (permeable reactive barrier [PRB]).

4.1 Source Control with Groundwater Polishing

Both federal and state regulators have long recognized that natural geochemical processes can be an acceptable component of a remedial action when it can achieve remedial action objectives in a reasonable timeframe. In 1999, USEPA published a final policy directive for groundwater remediation and described the process as follows:

- *"The reliance on natural attenuation processes (within the context of a carefully controlled and monitored site cleanup approach) to achieve site-specific remediation objectives within a time frame that is reasonable compared to that offered by other more active methods. The 'natural attenuation processes' that are at work in such a remediation approach include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in-situ processes include biodegradation; dispersion; dilution; sorption; volatilization; radioactive decay; and chemical or biological stabilization, transformation, or destruction of contaminants."* (USEPA, 1999).

The USEPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (USEPA, 1999). Natural geochemical processes may be appropriate as a "finishing step" after effective source control implementation (*i.e.*, groundwater polishing), to reduce the residual mass remaining in the groundwater after closure, if there are no risks to receptors and/or the contaminant plume is not expanding. Thus, groundwater polishing would be used in conjunction with the significant planned source control effort at the site, which will consist of a hybrid consolidate-and-cap approach with a final cover system described in **Section 1.2**.

In 2015, USEPA addressed remediation of inorganic compounds in groundwater and noted that the use of natural geochemical processes to address inorganic contaminants: (1) is not intended to constitute a treatment process for inorganic contaminants; (2) when appropriately implemented, can help to restore an aquifer to beneficial uses by immobilizing contaminants onto aquifer solids and providing the primary means for attenuation of contaminants in groundwater; and (3) is not intended to be a "do nothing" response (USEPA, 2015). Rather, documenting the applicability of natural geochemical processes for groundwater remediation should be thoroughly and adequately supported with site-specific characterization data and analysis (USEPA, 1999; USEPA, 2007; USEPA, 2015):

Both physical and chemical processes can contribute to the reduction of the small amount of residual mass remaining after closure of the WAPS, and the toxicity, mobility, volume, or concentration of contaminants in groundwater. Physical processes applicable to CCR include dilution, dispersion, and flushing. Chemical processes applicable to CCR include precipitation and coprecipitation (*e.g.,* incorporation into sulfide minerals) and sorption (*e.g.,* to iron, manganese, aluminum; to other metal oxides or oxyhydroxides; or to sulfide minerals or organic matter), and ion exchange (IX).

All inorganic compounds are subject to physical processes and under typical environmental conditions, physical mechanisms most often exert the dominant control on the CCR constituents of interest. Chemical mechanisms are also likely to be active, though not often dominant, such as adsorption, IX, and organic complexation. In combination with source control, these natural controls can provide an effective means to polish residual loading and achieve the GWPS in a reasonable timeframe. Additional data collection and analysis may be required to support the USEPA's evaluation framework (USEPA, 2015) and obtain regulatory approval.

4.2 Source Control with In-Situ Stabilization

ISS is a technology to treat impacted material using large diameter augers or other equipment to mix a slurry of pozzolanic additives, or reagents, into soils to solidify them in-situ. As the augers are advanced into the subsurface, the slurried reagent is blended with the soil, resulting in a subsurface mixture of soil and reagent. ISS results in a solidified mass with similar unit weights but with greater strength, lower permeability, and reduced contaminant mobility. ISS results in a column of mixed material which cures to a desired unconfined compressive strength of approximately 50 to 200 pounds per square inch (psi) after 28 days. Mixed columns typically cure relatively quickly, generally able to support construction equipment within 24 to 48 hours. Typically mixing sequencing will call for allowing mixed columns to cure for 24 to 48 hours before mixing a directly adjacent column. To treat all soil within a targeted area, adjacent columns are overlapped.

Typical ISS construction uses using large diameter rotary augers or hydraulic excavators to solidify/stabilize soil in place by mixing a cementitious grout with impacted soil. ISS implementation creates a stable and relatively impermeable, continuous, monolith having an unconfined compressive strength of greater than 50 psi. Full-scale ISS construction will result in volumetric expansion of the treated soil. The expansion, often referred to as "swell," is a result of blending reagent mixtures with the soil.

Typical ISS column diameters range from 3 to 12 feet. Various diameter columns may be used depending on the subsurface soil conditions, site constraints or layout, or project schedule. ISS columns will overlap forming a continuous solidified monolith. Columns will be spaced and overlapped to ensure all soils within the targeted area are thoroughly mixed. Each ISS column will include continuous application of reagent from the ISS platform surface (*i.e.,* base of excavation) to the design depth. There may be some limited areas where a shallower mixing profile is designed and mixing using a backhoe/excavator, commonly referred to as bucket mixing, may prove to be more efficient than vertical rotary mixing system. Bucket mixing operations consist of using the excavator to mix the soils to the design depth. Grout is pumped into the excavation from the grout plant via hoses. The soil is mixed with the grout from the base to the top of the treatment cell until the material appears adequately homogenized.

ISS is not widely used as a corrective measure for CCR applications but has been successfully implemented at power stations for other (*i.e.,* structural) applications. A combination of factors, including geologic heterogeneities and potential subsurface obstructions in the ash could limit the effectiveness of implementation.

4.3 Source Control with Groundwater Extraction

Groundwater extraction is one of the most widely used groundwater corrective technologies and has a long history of performance. This corrective measure includes installation of one or more groundwater pumping wells or trenches to control and extract impacted groundwater. Groundwater extraction captures and contains impacted groundwater and can limit plume expansion and/or off-site migration. Construction of a groundwater extraction system typically includes, but is not limited to, the following primary components:

- Designing and constructing a groundwater extraction system consisting of one or more extraction wells and operating at a rate to allow capture of CCR impacted groundwater within the UA.
- Management of extracted groundwater, which may include modification to the existing NPDES permit.
- Ongoing inspection and maintenance of the groundwater extraction system.

Remediation of inorganics by groundwater extraction can be effective, but systems do not always perform as expected. A combination of factors, including geologic heterogeneities, difficulty in flushing low-permeability zones, and rates of contaminant desorption from aquifer solids can limit effectiveness. Groundwater extraction systems require ongoing operation and maintenance to address issues such as iron bacteria and well fouling and to ensure optimal performance. The extracted groundwater must be managed, either by ex-situ treatment or disposal.

Groundwater extraction may reduce the timeframe to achieve GWPS and contain the groundwater constituents that exceed the GWPS. Extraction could be accomplished using a groundwater pumping well system or an extraction trench.

4.4 Source Control with a Cutoff Wall

Since the late 1970s and early 1980s, vertical cutoff walls have been used to control and/or isolate impacted groundwater. Low-permeability cutoff walls can be used to prevent horizontal off-site migration of potentially impacted groundwater. Cutoff walls act as barriers to transport of impacted groundwater and can isolate soils that have been impacted by CCR to prevent contact with unimpacted groundwater. Cutoff walls are often used in conjunction with an interior pumping system to establish an inward gradient within the cutoff wall. The gradient imparted by the pumping system maintains an inward flow through the wall, keeping it from acting as a groundwater dam and controlling potential end-around or breakout flow of contaminated groundwater. Constructing the cutoff wall such that it intersects a low-permeability material at its base, referred to as "keying", greatly increases its effectiveness.

A commonly used cutoff wall construction technology is the slurry trench method, which consists of excavating a trench and backfilling it with a soil-bentonite mixture, often created with the excavated soils, or, for deeper walls, a cement-bentonite mixture that is produced at an onsite batch plant. The trench is temporarily supported with bentonite slurry pumped into the trench during excavation (D'Appolonia & Ryan, 1979). Cutoff wall excavation uses conventional hydraulic excavators, hydraulic excavators equipped with specialized booms to extend their reach (*i.e.,* long-stick excavators), clamshells, or more specialized equipment such as hydromills or secant-pile drill rigs, depending upon trench depth, material excavated, and type of material that the wall is keyed into.

Cutoff walls are a widely accepted technology for containing impacted groundwater. Combining groundwater polishing with a limited cutoff wall and groundwater extraction in specific areas may provide advantages over independent use of these potential corrective technologies. Cutoff walls can be used in combination with groundwater extraction or as part of a PRB system (as the "funnel" in a funnel-and-gate system; **Section 4.5**).

4.5 Source Control with In-Situ Chemical Treatment

The use of in-situ treatment, either by injection or PRBs is a widely used technology for treating impacted groundwater. However, in-situ treatment techniques for arsenic, boron, lithium, and sulfate are not well established; therefore, performance is unknown.

Chemical treatment could consist of injection of reactive materials into the subsurface to treat contaminants at specific, targeted locations. Alternately, treatment via PRB, where reactive materials are placed in the subsurface at locations designed to direct the contaminant plume along a flow path through the reactive media. In either system, the contaminants are transformed or otherwise rendered into environmentally acceptable forms to attain remediation concentration goals downgradient of the barrier (Electric Power Research Institute [EPRI], 2006).

As groundwater passes through the PRB under natural gradients, dissolved constituents in the groundwater react with the media and are transformed or immobilized. A variety of media have been used or proposed for use in PRBs. Zero-valent iron (ZVI) has been shown to effectively immobilize some CCR constituents, including arsenic, chromium, cobalt, molybdenum, selenium,

and sulfate. Use of a combination media consisting of ZVI and a boron-selective IX resin to treat boron has been documented in a pilot-scale test (EPRI, 2006).

System configurations include continuous PRBs, in which the reactive media extends across the entire path of the contaminant plume; and funnel-and-gate systems, where low-permeability barriers are installed to control groundwater flow through a permeable gate containing the reactive media. Continuous PRBs intersect the entire contaminant plume and do not materially impact the groundwater flow system. Design may or may not include keying the PRB into a low-permeability unit at depth. Funnel-and-gate systems utilize a system of barriers to groundwater flow (funnels) to direct the contaminant plume through the reactive gate. The barriers, typically some form of cutoff wall, are keyed into a low-permeability unit at depth to prevent short circuiting of the plume. Funnel-and-gate design must consider the residence time to allow chemical reactions to occur. Directing the contaminant plume through the reactive gate can significantly increase the flow velocity, thus reducing residence time.

Design of in-situ treatment systems requires rigorous site investigation to characterize the site hydrogeology and to delineate the contaminant plume. A thorough understanding of the geochemical and redox characteristics of the plume is critical to assess the feasibility of the process and select appropriate reactive media. Laboratory studies, including batch studies and column studies using samples of site groundwater, are needed to determine the effectiveness of the selected reactive media at the site (EPRI, 2006). The main considerations in selecting reactive media are as follows (Gavaskar et al., 1998 as cited by EPRI, 2006):

- Reactivity - The media should be of adequate reactivity to immobilize a contaminant within the residence time of the design.
- Hydraulic performance - The media should provide adequate flow through the PRB, meaning a greater particle size than the surrounding aquifer materials. Alternatively, gravel beds have been emplaced in front of barriers to direct flow through the barrier.
- Stability - The media should remain reactive for an amount of time that makes its use economically advantageous over other technologies.
- Environmentally compatible by-products - Any by-products of media reaction should be environmentally acceptable. For example, iron released by zero-valent iron corrosion should not occur at levels exceeding regulatory acceptance levels. Availability and price: The media should be easy to obtain in large quantities at a price that does not negate the economic feasibility of using a PRB.
- Availability and price: The media should be easy to obtain in large quantities at a price that does not negate the economic feasibility of using a PRB.

5. ASSESSMENT OF CORRECTIVE MEASURE TECHNOLOGIES

This CMA was initiated to address exceedances of the 35 I.A.C. § 845.600 GWPS at the downgradient waste boundary of the WAPS identified during the E001 groundwater monitoring event (**Section 2.2**).

5.1 Requirements

The potential groundwater corrective technologies described in the previous section were evaluated relative to the requirements presented in **Section 3** and reiterated below:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the CAP; and
- Institutional requirements, such as State or local permit requirement or other environmental or public health requirements that may substantially affect implementation of the CAP.

Table 5-1 presents the qualitative CMA evaluations of the of each groundwater technology against these requirements, as well as their ability to address GWPS exceedances. The following sections provide a summary of these evaluations and a discussion of the potential groundwater corrective measure technologies that may be viable, either independently or in combination, to address GWPS exceedances. This section also provides a summary of corrective measure technologies that have been retained and advanced for evaluation as part of the CAAA process for selecting the final remedy for the WAPS per 35 I.A.C. § 845.670.

5.2 Groundwater Corrective Technology Assessment

Source control, consisting of a hybrid consolidate-and-cap approach comprised of CBR of the OWPP and CIP of the OWAP, will be the primary groundwater corrective measure for the WAPS. Closure was completed in 2020 and each of the potential groundwater corrective measure technologies would supplement the positive impact of prior closure activities. The following sections evaluate groundwater corrective measure technologies that, when combined with site closure, may be viable to address GWPS exceedances. Technologies that are not viable for addressing the GWPS at the WAPS will be eliminated from further evaluation and viable technologies will be advanced for further evaluation as part of the CAAA process per 35 I.A.C. § 845.600.

5.2.1 Source Control with Groundwater Polishing

Source control construction (**Section 1.2**) has reduced the mass loading to the groundwater system to the extent that aquifer polishing process could act upon CCR constituents in the UA. Hydrostatic modeling and groundwater flow and fate and transport modeling indicated that source control construction would reduce the hydraulic head to near-zero level (equilibrium condition) within seven years after completion of cap construction and decrease transport of CCR constituents off-site. Ongoing groundwater modeling, which is expected to be completed in 2025, indicates that GWPS will be met approximately 30 years after the remedy implementation for the wells currently included in the compliance well network.

Groundwater polishing by natural geochemical processes is a widely accepted component of groundwater remediation and is routinely approved by the IEPA when paired with source control. The performance of groundwater polishing as a groundwater corrective measure varies based on site-specific conditions and additional data collection may be needed to support the design and regulatory approval. The sandy nature of the UA suggests good performance by physical processes in addressing the arsenic, boron, sulfate, lithium, and TDS in the UA.

Naturally occurring geochemical processes are ongoing at the WAPS and will continue to affect groundwater constituent concentrations. Ongoing monitoring of groundwater conditions is needed to better understand the mechanisms and efficacy of the groundwater polishing process and to confirm the effectiveness over time. Thus, additional groundwater sample collection and analyses would be required to characterize potential mechanisms, as discussed above, and to provide long term monitoring of the remedial progress. Enhancements to the groundwater monitoring system may be required to ensure that the aquifer polishing is occurring as predicted, consistent with the adaptive site management approach. The reliability of aquifer polishing as a groundwater corrective measure is high because operation and maintenance requirements are limited. However, the reliability can also vary based on site-specific hydrogeologic and geochemical conditions.

Following characterization and approval of the CAP, monitoring of the groundwater polishing processes and comparison to functional goals established to monitor progress toward the remedial objective could begin as quickly as within a few months of CAP approval.

No potential safety impacts or exposure to human health or environmental receptors are expected to result from the groundwater polishing processes. Timeframes to achieve GWPS are dependent on site-specific conditions, which require detailed technical analysis (ongoing at this time). Selecting groundwater polishing as a corrective measure for the WAPS will require approval of the CAP permits by the IEPA.

Monitoring the groundwater polishing to track progress toward achievement of the GWPS after the 2020 completion of source control construction at the WAPS would require long-term maintenance and monitoring of the groundwater monitoring system to confirm source control and verify the effectiveness in reducing groundwater concentrations to levels below the GWPS. Monitoring activities could be initiated immediately after approval of the CAP permit.

Groundwater polishing processes will continue to occur naturally at the FAPS. It may be a viable corrective measure for the arsenic, boron, sulfate, lithium, and TDS exceedances at the WAPS. Therefore, these processes are being advanced to the CAAA for further evaluation.

5.2.2 Source Control with In-Situ Stabilization

Source control will reduce the mass loading to the groundwater system and ISS was considered as a method of supplementing the completed source control. ISS is typically infeasible for large site and/or deep CCR; however, it was considered at the WAPS due to the limited size of the impoundment and limited depth to CCR. Implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. Targeting zones of the CCR in the WAPS using ISS to solidify/stabilize CCR that is present at and below the groundwater level observed in surrounding monitoring wells at normal conditions could reduce or prevent the continued migration of CCR-related constituents away from the WAPS. When combined with groundwater polishing, ISS may reduce the time required to attain GWPS.

ISS is not a common corrective measure for CCR impacted groundwater, but it is a widely accepted corrective measure used to control and/or isolate impacted groundwater and it is routinely approved by regulatory agencies. ISS have a long history of reliable performance as a groundwater remediation technique.

ISS construction may be challenging due to the presence of potential obstructions in the CCR (*i.e.,* debris in the ash) which could impede advancement of the large diameter augers used to construct the ISS monolith. ISS construction in the already closed WAPS would be complicated and would likely require removal and reconstruction of the final cover system, which could cause a temporary reversal of some of the completed source control activities.

Construction could be completed within 2 to 3 years. Time of implementation is approximately 4 to 5 years, including characterization, design, permitting and construction. ISS would be used to supplement the completed source control and may require additional corrective measures, such as groundwater polishing, to attain GWPS.

Completing ISS in the WAPS would require IEPA approval of the CAP permit and, depending on the location, an IDNR dam safety modification permit may be required.

Supplementing source control using ISS could be used to reduce or prevent the continued migration of CCR-related constituents away from the WAPS. When combined with groundwater polishing, ISS may reduce the time required to attain GWPS. Therefore, ISS is being advanced to the CAAA for further evaluation.

5.2.3 Source Control with Groundwater Extraction

The completed source control is reducing the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA.

Groundwater extraction is a widely accepted corrective measure with a long track record of performance and reliability. It is routinely approved by the IEPA. For a corrective measure using groundwater extraction to effectively control off-site flow and/or to remove potentially contaminated groundwater, horizontal and vertical capture zone(s) must be created. The performance of a groundwater extraction system would be expected to be effective in the high permeability UA. However, the proximity and influence of the Illinois River to the impacted area of the UA would potentially result in large volumes of extracted groundwater and river water. Cutoff walls (**Section 4.4**) could be used in conjunction with a pumping system to control potential groundwater movement from the river.

Implementation of a groundwater extraction system presents design challenges due to the proximity to the Illinois River. An extraction system in the UA would have to consider the potential for extracting unimpacted river water. Construction of an extraction system may be challenging due to the presence of cobbles and potentially large boulders in the UA. Specialty drilling methods may be required to construct the extraction system. Extracted groundwater (and potentially river water) would need to be managed, which may include modification to the existing NPDES permit and treatment prior to discharge, if necessary. Specialized treatment equipment may be required, and ongoing operations and maintenance activities would be necessary.

There could be some impacts associated with constructing and operating a groundwater extraction system, including some limited exposure to extracted groundwater. Additional data collection and analyses would be required to design an extraction system. Construction could be completed within 1 year following completion of a final design. Time of implementation is approximately 3 to 4 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on site-specific conditions. An extraction system may reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling. However, the relatively long expected GWPS attainment times may result in operations and maintenance of a groundwater extraction system for decades of years or more.

Implementing a groundwater extraction system at the WAPS would require IEPA approval of the CAP permit, and discharge of extracted groundwater may require a modification to the NPDES permit, as well as possibly permitting and construction of a new outfall. Depending upon the location of the extraction system an Illinois Department of Natural Resources (IDNR) dam safety modification permit may also be required to construct an extraction system.

Groundwater extraction could be viable corrective measure for the arsenic, boron, sulfate, lithium, and TDS exceedances at the WAPS. Implementation of groundwater extraction would require combining an extraction system with a cutoff wall to prevent very high inflow volumes from the Illinois River. Therefore, groundwater extraction is not being advanced to the CAAA for further evaluation.

5.2.4 Source Control with Groundwater Cutoff Wall

The completed source control is reducing the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. A low permeability cutoff wall could provide long-term, maintenance-free physical barrier to significantly reduce or prevent horizontal migration of CCR-impacted groundwater away from the WAPS. A cutoff wall could be used in combination with a groundwater extraction system in the UA to reduce the potentially high volumes of extracted groundwater that would be captured by and extraction system between the WAPS and the Illinois River. A cutoff wall could reduce the water management and treatment requirements for an extraction system.

Groundwater cutoff walls are a widely accepted corrective measure used to control and/or isolate impacted groundwater and are routinely approved by the IEPA. Cutoff walls have a long history of reliable performance as hydraulic barriers, provided they are properly designed and constructed. However, if not coupled with a groundwater extraction system, a cutoff wall will provide directional groundwater control only and may result in redistribution of contaminants and potentially GWPS exceedances at new locations.

Cutoff walls are designed to act as hydraulic barriers; as a result, cutoff walls inherently alter the existing groundwater flow system. Changes to the existing groundwater flow system may need to be controlled to maximize the effectiveness of the remedy by, for example, combining a cutoff wall with groundwater extraction to control build-up of hydraulic head upgradient and around the cutoff walls. Construction of a cutoff wall extending into the UA would be challenging, if it is possible, and would require specialized and highly experienced contractors with non-standard construction equipment due to the presence of subsurface cobbles and boulders.

Constructing a cutoff wall may also be challenging due to the physical site constraints (limited construction area due to the proximity of the Illinois River), particularly if used in combination with an extraction system. In that case, both the extraction system and the cutoff wall would need to be located between the WAPS and the river, which would increase the construction complexity and could result in structural impacts to the embankment dikes, depending on the location of the wall.

Additional data collection and analyses would be required to design a cutoff wall. Construction could be completed within 2 to 3 years. Time of implementation is approximately 5 to 8 years, including characterization, design, permitting, and construction. To attain GWPS, cutoff walls require a separate groundwater corrective measure to operate in concert with the cutoff wall(s). Cutoff walls are commonly coupled with aquifer polishing and/or groundwater extraction as groundwater corrective measures. The time to attain GWPS is dependent on the selected groundwater corrective measure or measures that are coupled with the cutoff walls.

Constructing a cutoff wall at the WAPS would require IEPA approval of the CAP permit and, depending on the location, an IDNR dam safety modification permit may be required.

A cutoff wall alone would not be a viable corrective measure for the arsenic, boron, sulfate, lithium, and TDS exceedances at the WAPS. Cutoff walls are commonly coupled with groundwater polishing and/or groundwater extraction as groundwater corrective measures. However, a cutoff wall could provide long-term, maintenance-free physical barrier to significantly reduce or prevent horizontal migration of CCR-impacted groundwater away from the WAPS. Therefore, the cutoff wall is being advanced to the CAAA for further evaluation.

5.2.5 Source Control with In-Situ Chemical Treatment

Source control will reduce the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. Use of in-situ treatment, either through targeted injection of reactive media or in PRB systems, to transform contaminants into environmentally acceptable forms to attain the GWPS was considered.

In-situ treatment using IX to address arsenic, boron, lithium, sulfate, and TDS exceedances in groundwater is not an established or widely accepted groundwater corrective measure; therefore, its performance and reliability are unknown. Regulatory acceptance of this innovative approach to achieving the GWPS is uncertain.

In-situ treatment in the granular UA is expected to be relatively straightforward using targeted reactive media delivery via injection, however use of a PRB would present design and construction challenges similar to the challenges with constructing a cutoff wall discussed above due to the presence of cobbles and boulders. Depending upon the location of the PRB system, construction may affect the WAPS embankment and/or final cover system and periodic change-outs of IX resin media may be required.

Additional data collection and analyses would be required to design an in-situ treatment system and bench scale and/or pilot scale testing may be required to demonstrate performance and reliability. Time of implementation is approximately 4 to 6 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on demonstrations of performance and reliability and on ultimate regulatory

acceptance. It is not known whether in-situ treatment would reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling.

Due to the uncertain performance, reliability and potential for regulatory acceptance, in-situ chemical treatment is not a viable corrective measure for the arsenic, boron, sulfate, lithium, and TDS exceedances at the WAPS and is not being advanced to the CAAA for further evaluation.

5.3 Technologies Advanced to CAAA

Based on the evaluations presented above, the following potential corrective technologies are being advanced to the CAAA for more detailed evaluations, individually or in combination, and cost estimation:

- Source control with groundwater polishing;
- Source control and with ISS; and
- Source control with a groundwater cutoff wall.

Remedy	Evaluation Factors						
	Performance	**Reliability**	**Ease of Implementation**	**Potential Impacts of Remedy (safety impacts, cross-media impacts, control of exposure to any residual contamination)**	**Time Required to Begin and Implement Remedy[1]**	**Time to Attain Groundwater Protection Standards**	**Institutional Requirements (state/local permit requirements, environmental/public health requirements that affect implementation of remedy)**
Source Control with Groundwater Polishing	Performs best paired with source control which was completed in 2020.	Ongoing analysis will evaluate if the attenuation mechanism has low reversibility, if the aquifer has sufficient capacity, and if the hydrogeology is favorable for arsenic, boron, sulfate and/or lithium physical processes. Arsenic in the uppermost aquifer conditions may be more amenable to physical processes.	Evaluation is underway and is expected to be completed in 2024. Long-term monitoring would be required. Implementing would not require extensive specialized equipment or contractors	None identified.	Approximately 90 days after CAP permit approval.	Dependent on site-specific conditions. Ongoing analysis will evaluate attenuation rate and capacity.	IEPA approval of the CAP permit is required. No institutional requirements are anticipated. The approved the Closure Plan for source control included a Groundwater Management Zone application for locations and identified parameters.
Source Control with In-Situ Stabilization	Supplement source control using in-situ stabilization within targeted zones of the CCR, combined with groundwater polishing for impacts beyond the CCR.	Not widely used as a corrective measure for CCR applications but has been successfully implemented at power stations for other (*i.e.,* structural) applications.	Presence of potential obstructions (*i.e.,* debris) in the ash could inhibit implementation.	Would require temporarily disturbing and reconstructing the existing final cover system; this may temporarily reverse some of the completed source control effects.	Design, permitting and construction is expected to take 4 to 5 years after CAP approval.	Would likely reduce the time to less than the post closure timeframe predicted by the groundwater model for source control and groundwater polishing only.	IEPA approval of the CAP permit is required. A IDNR dam safety modification permit might also be required, depending on the location of the ISS installation.
Source Control with Groundwater Extraction	A widely accepted, routinely approved technology. Performance is generally good in granular aquifers, however the highly permeable nature of the Uppermost Aquifer would likely require high flow rates. May be uncertainty in expected performance due to the proximity to the river and potential for flood events.	Reliable if properly designed, constructed and maintained. Likely not reliable without cutoff wall due to the high permeability of the Uppermost Aquifer and proximity to the river.	Specialized drilling techniques (*i.e.,* sonic) may necessary for groundwater extraction system construction due to the presence of cobbles/boulders. Extracted groundwater flow rates could be very high and would require management, possibly including treatment, which may also require specialized equipment/contractors.	Alters groundwater flow system. Potential for some limited exposure to extracted groundwater. Groundwater extraction may induce settlement, which could cause structural impacts to the embankments, final cover system and/or adjacent structures. High flow rates may increase the difficulty in water management/treatment requirements.	Design, permitting and construction is expected to take 3 to 4 years after CAP permit approval.	Dependent on site-specific conditions. Less than the post-closure timeframe predicted by the groundwater model for source control and groundwater polishing.	IEPA approval of the CAP permit is required. IEPA approval is anticipated to be required for discharge of extracted groundwater via a NPDES discharge permit. An IDNR dam safety modification permit might also be required, depending on location of wells and settlement potential.
Source Control with Groundwater Cutoff Wall	Widely accepted, routinely approved, good performance if properly designed and constructed. May need to be combined with another groundwater corrective measure, such as groundwater polishing or extraction, to achieve GWPS.	Reliable for groundwater directional control if properly designed and constructed.	Widely used, established technology. Due to the depth to the uppermost aquifer and presence of cobbles/boulders, construction would likely require specialized, highly experienced contractors with non-standard construction equipment. Space limitations may be challenging for installing the wall and relocating compliance well system.	Alters groundwater flow system but does not provide any treatment. Can result in unintended consequences resulting from redirecting contaminants to areas where they are not currently present. May cause structural impacts to the embankment dikes, depending on the location of the wall. May require disturbing and reconstructing portions of the existing final cover system and other aspects of the completed closure, depending on the location of the wall; this may temporarily reverse some of the completed source control effects.	Design, permitting and construction is expected to take 5 to 8 years after CAP permit approval. Uncertainty in implementation time due to need for specialty contractors and expected difficult installation conditions.	Needs to be combined with other groundwater corrective measure(s). Time required to attain GWPS dependent on combined measures.	IEPA approval of the CAP permit is required. An IDNR dam safety permit may also be required depending on the location of the cutoff wall.
Source Control with In-Situ Chemical Treatment	In-Situ treatment not well established for boron, sulfate or lithium, therefore performance is unknown. In-situ treatment of arsenic is feasible. Performance would be poor because it would be limited to a single constituent.	Unknown reliability for arsenic, boron, sulfate, and/or lithium.	The granular nature of uppermost aquifer would likely be amenable to in-situ chemical delivery.	May require disturbing and reconstructing portions of the existing final cover system and other aspects of the completed closure, depending on the type and delivery method for the treatment. This may temporarily reverse some of the completed source control effects.	May require bench scale and/or pilot scale testing as part of design. Design, permitting and construction is expected to take 4 to 6 years after CAP approval.	There is uncertainty regarding whether a in-situ treatment would reduce arsenic, boron, sulfate, or lithium concentrations to achieve the GWPS. Dependent on conditions specific to the reactive media used and the site. Treatment technology is not well understood.	IEPA approval of the CAP permit is required. IEPA approval of this innovative and relatively unproved solution may be challenging. A IDNR dam safety permit may also be required if a PRB is used, depending on the location.

Notes:
[1] Time required to begin and implement remedy includes design, permitting, and construction.

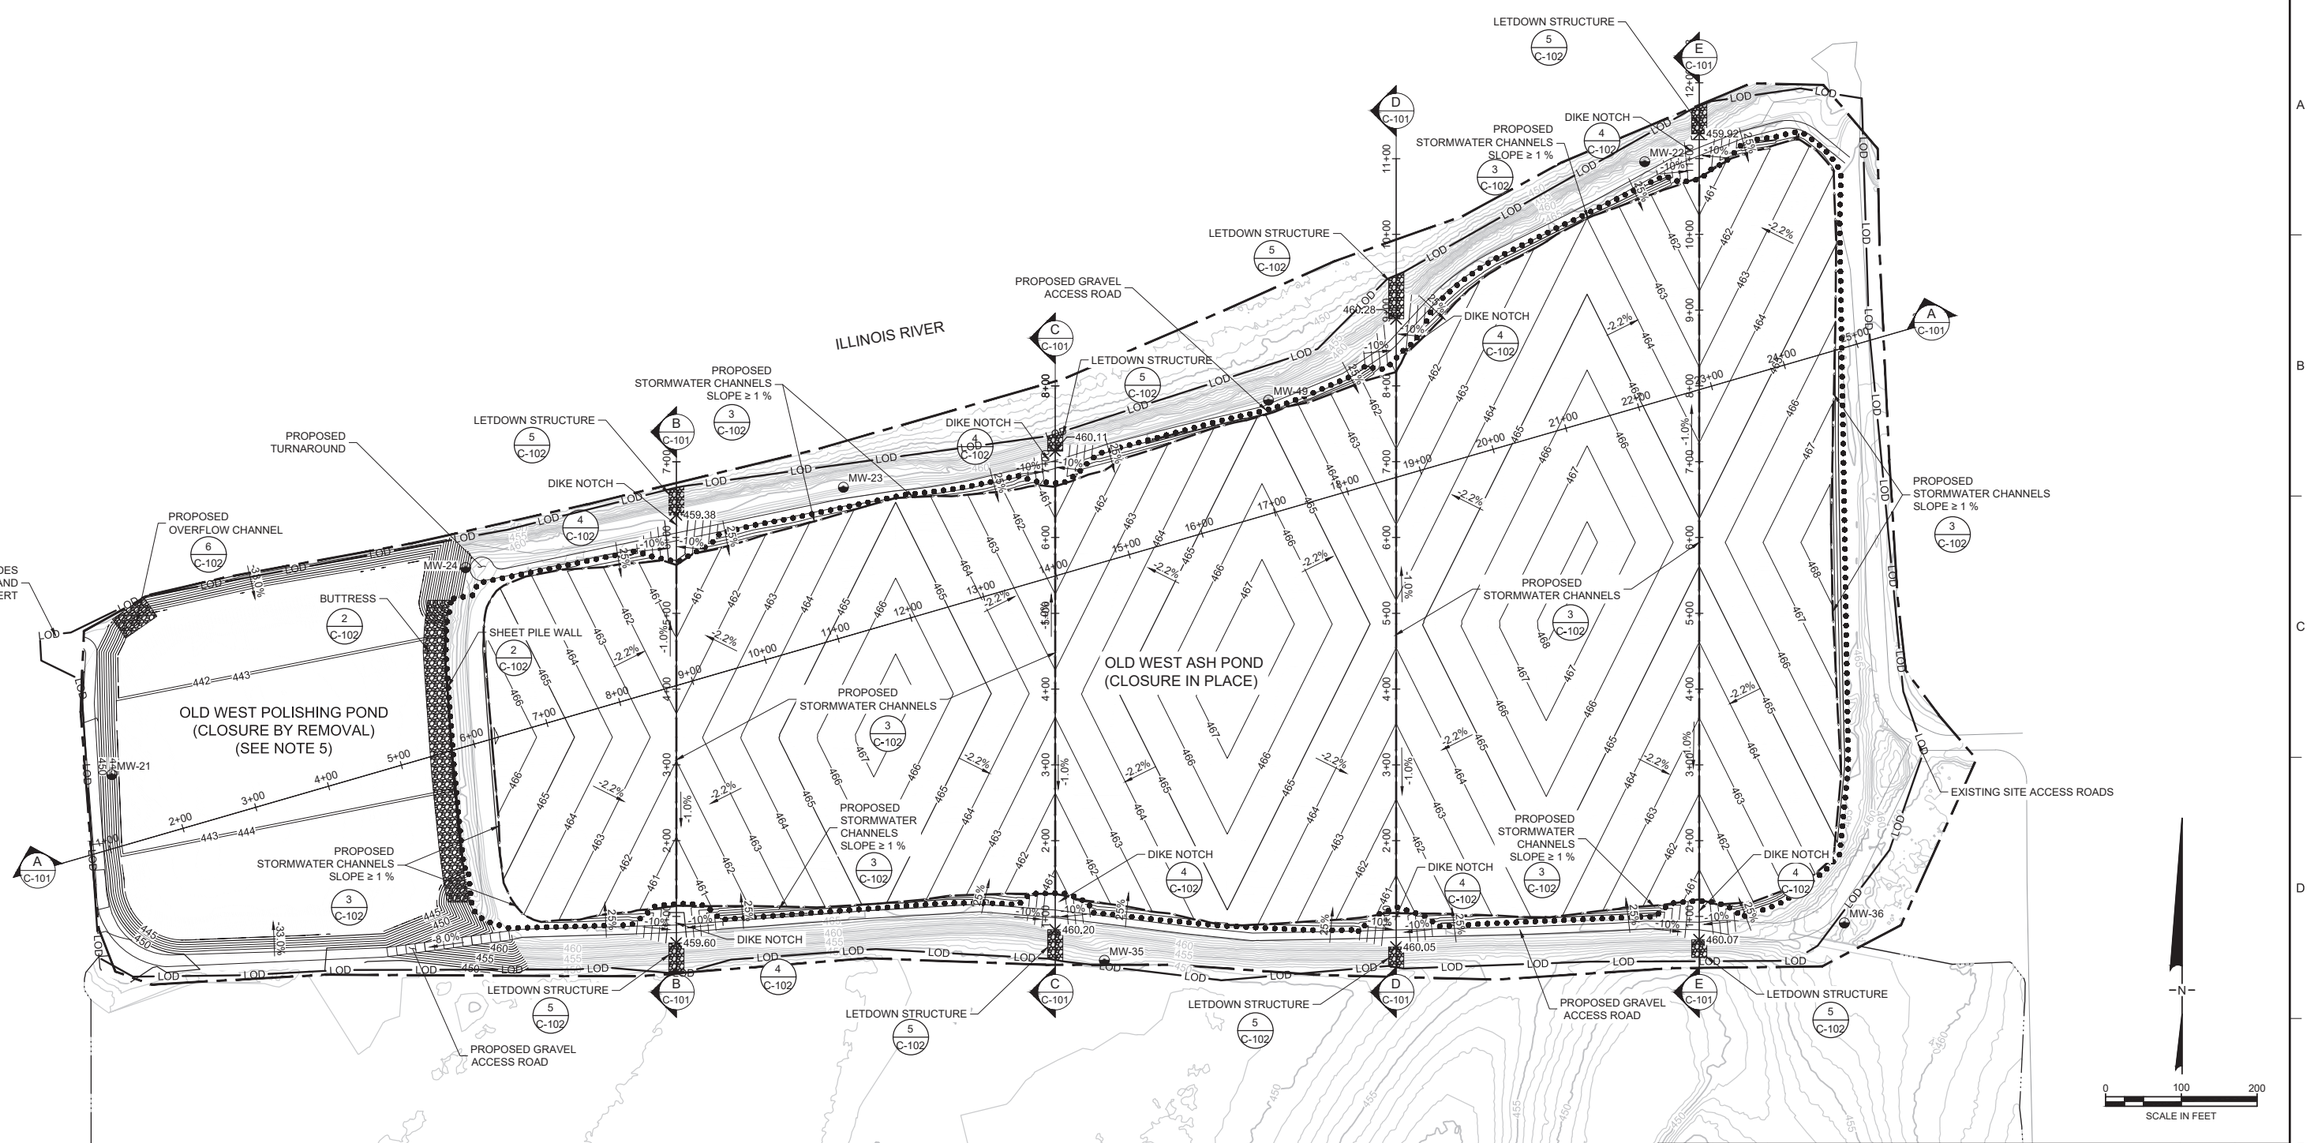
Attachment A – Selected Closure Plan Drawings



NOTES:

1. WEST ASH BASIN TOPOGRAPHIC SURVEY PROVIDED BY DYNEGY, TITLED "HENNEPIN 2015 AERIAL TOPOGRAPHY EXISTING SITE CONDITIONS", SURVEYED BY WEAVER CONSULTANTS GROUP, DATED DECEMBER 1, 2015.
2. TOPOGRAPHIC SURVEY SOUTH OF THE OLD WEST ASH POND AND OLD WEST POLISHING POND WAS PROVIDED BY INGENAE, TITLED "2017 TOPOGRAPHY", DATED JUNE 15, 2017.
3. COORDINATES AND DIRECTIONS SHOWN ON THIS DRAWING ARE BASED ON ILLINOIS STATE PLANE COORDINATE SYSTEM (NAD83) (US FEET). ELEVATIONS ARE BASED ON NORTH AMERICAN VERTICAL DATUM OF 1988 (NAVD88) (US FEET).
4. GRADING SHOWN ON THIS PLAN IS THE TOP OF FINAL COVER, WHICH IS TWO FEET ABOVE TOP OF SUBGRADE.
5. THE OLD WEST POLISHING POND WILL BE CLOSED BY REMOVAL OF CCR. AFTER CLOSURE, THE FORMER OLD WEST POLISHING POND WILL BE VEGETATED AND FUNCTION AS SHALLOW POND. THE ONLY INFLOW INTO THE FORMER OLD WEST POLISHING POND WILL BE PRECIPITATION THAT FALLS DIRECTLY INTO THE POND AND WATER FROM THE ADJACENT ILLINOIS RIVER THAT WILL FLOW INTO THE POND DURING HIGH-WATER EVENTS.
6. ALL DENSE, WOODY VEGETATION (I.E. TREES, SHRUBS) INSIDE THE LIMITS OF DISTURBANCE WILL BE REMOVED AS PART OF CLOSURE CONSTRUCTION. THE DISTURBED AREAS WILL BE RE-VEGETATED WITH GRASSES AS PART OF CLOSURE CONSTRUCTION.

EARTHWORK VOLUMES TO REACH DESIGN SUBGRADES			
CUT (PRE-COMPACTION)		FILL (POST COMPACTION)	
OLD WEST POLISHING POND	61,000 CY	OLD WEST POLISHING POND	0 CY
OLD WEST ASH POND	36,000 CY	OLD WEST ASH POND	80,000 CY
TOTAL	97,000 CY	TOTAL	80,000 CY

NOTES:

1. CUT MATERIAL IS ASSUMED TO REDUCE IN VOLUME BY 18% DUE TO COMPACTION. THEREFORE, THE TOTAL VOLUME OF CUT MATERIAL AVAILABLE FOR COMPACTED FILL IS 80,000 CY, RESULTING IN BALANCED CUT AND FILL QUANTITIES.
2. CUT AND FILL QUANTITIES ARE ONLY THOSE REQUIRED TO REACH DESIGN SUBGRADES. OTHER EARTHWORK QUANTITIES, SUCH COVER SOIL, BUTTRESS FILL, AND LETDOWN STRUCTURES ARE NOT INCLUDED IN THESE QUANTITIES.

EXECUTIVE SUMMARY

Groundwater samples collected at the Hennepin Power Plant (HPP) West Ash Pond System (WAPS) during May and June 2023 for the Quarter 2, 2023 compliance sampling event (Event 1 [E001]) were evaluated for exceedances of the groundwater protection standards (GWPS) described in Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845.600. Exceedances were identified in the following wells in the uppermost aquifer (UA):

- Arsenic at 21R and 51
- Boron at 21R, 22, 23, and 35
- Cadmium at 22
- Sulfate at 23 and 35

In accordance with 35 I.A.C. § 845.650(e), an Alternative Source Demonstration (ASD) was completed for the cadmium exceedance at well 22 and received concurrence in a letter from the Illinois Environmental Protection Agency (IEPA) dated December 11, 2023 [1, 2]. A Corrective Measures Assessment (CMA) was initiated on December 10, 2023 and submitted on May 8, 2024 in accordance with 35 I.A.C. § 845.660 for the remaining E001 exceedances [3].

The subsequent compliance sampling events for the Quarter 3 and Quarter 4, 2023 sampling events (Event 2 [E002] and Event 3 [E003]) were completed in August and November 2023 and groundwater samples were evaluated for exceedances of the GWPS as described in 35 I.A.C. § 845.600. Additional exceedances were identified in the following wells in the UA during the E002 and E003 events:

- Lithium at 22
- Total Dissolved Solids (TDS) at 35

The E002 and E003 exceedances of lithium at well 22 and TDS at well 35 were evaluated with respect to the groundwater model, potentially feasible corrective measures, and remedy extents and were determined not to substantially affect the findings and conclusions of the previously initiated CMA evaluation and therefore have been incorporated into the CMA and this report.

As required by 35 I.A.C. § 845.650(d)(1) this report characterizes the nature and extent of arsenic, boron, lithium, sulfate, and TDS and relevant site conditions to determine how they may affect the corrective measures ultimately selected for the WAPS and documents the additional measures taken in accordance with 35 I.A.C. § 845.650(d).

All of the aforementioned chemicals of concern (COCs) were detected above the GWPS within the UA. The lateral and downgradient extent of these COCs in the UA is adequately defined by sampling of existing monitoring wells and surface water samples. The vertical migration of these COCs above the GWPS in the UA is limited by low hydraulic conductivity of the Bedrock Confining Unit (Carbondale Formation) underlying the UA [4]. The concentrations of arsenic, boron, lithium, sulfate and TDS within the UA are attenuated physically through dilution and dispersion; and may be geochemically attenuated by surface complexation reactions with metal oxyhydroxides and clays. Concentrations of exceedance parameters in the Illinois River were evaluated and they do not exceed their respective GWPS.

1. INTRODUCTION

35 I.A.C. § 845.650(d)(1) requires the owner or operator of a coal combustion residuals (CCR) surface impoundment (SI) to characterize the nature and extent of a release and relevant site conditions that may affect the remedy ultimately selected for a CCR SI if any constituent regulated under 35 I.A.C. § 845 is found to exceed the GWPS. This report documents the nature and extent of constituents detected above the GWPS that are attributable to the HPP WAPS.

The groundwater data and analysis in this report includes results from historical sampling (initiated in 2015) through E003, which was completed on November 15, 2023. Results of the events E001, E002, and E003 were submitted and placed in the facility's operating record within 60 days of receiving final laboratory analytical data [5, 6, 7] as required by 35 I.A.C. § 845.800(d)(15). The statistical determination presented in these reports identified the following exceedances of the GWPS at compliance groundwater wells in the UA:

- Arsenic at 21R and 51
- Boron at 21R (E001 only), 22, 23, and 35
- Cadmium at 22
- Lithium at 22
- Sulfate at 23 and 35
- TDS at 35

An ASD, as allowed by 35 I.A.C. § 845.650(e), was completed for the cadmium exceedance at UA monitoring well 22 [2]. The IEPA concurred with the ASD in a letter dated December 11, 2023 [1]. Therefore, the nature and extent of cadmium is not discussed in this document. This Nature and Extent Report discusses in detail the extent of arsenic, boron, lithium, sulfate, and TDS exceedances as well as a geochemical conceptual site model (GCSM) describing the nature of these exceedances.

2. UNIT BACKGROUND

2.1 Site Location and Description

The HPP is an approximately 504-acre property consisting of 19 parcels positioned adjacent to the Illinois River, including a retired coal-fired power plant, CCR landfill and SIs, and farmland, located approximately 3 miles north-northeast of the Village of Hennepin, Illinois, in Putnam County. The HPP construction history includes construction of Unit 1 in 1953 and Unit 2 in 1969, with capacities of 70 megawatts (MW) and 210 MW, respectively. The plant initially burned high-sulfur Illinois coal and switched to sub-bituminous Powder River Basin coal in 1999 [8]. The HPP ceased operations in 2019 when the power plant was retired.

The WAPS is one of three CCR units at the HPP regulated under 35 I.A.C. § 845. The other two CCR units regulated under 35 I.A.C. § 845 (Ash Pond Number [No.] 2 and No. 4 multi-unit [AP2/AP4] and the East Ash Pond) are located adjacent to each other and the Landfill, east of the HPP. The WAPS is located west of the HPP. Areas surrounding the WAPS include agricultural land, with scattered groupings or rows of trees to the southeast, and low-lying floodplains of the Donnelley Wildlife Management Area to the southwest and west. The WAPS and surrounding properties are shown on **Figure 2-1**.

2.2 Description of CCR Unit

Dynegy Midwest Generation, LLC (DMG) operated the WAPS from 1952 through 1996. It consists of two closed units, the Old West Ash Pond (OWAP; IEPA Unit Identification [ID] W1550100002-01) and the Old West Polishing Pond (OWPP; IEPA Unit ID W1550100002-03) (**Figure 2-2**). The OWAP consists of the 9.3-acre Pond No. 1 at the eastern end of the impoundment and the 16.4-acre Pond No. 3 within the central portion of the impoundment. The 4.7-acre OWPP is situated at the western end of the impoundment. All ponds were previously bermed to approximately 15 feet above grade primarily using locally occurring soils. The OWPP berms were excavated and removed to obtain access to CCR material used within and below them during closure construction of this unit in 2020.

During operation, water was used to sluice fly ash, bottom ash, and low-volume wastes to the WAPS. At the time it was removed from service in late 1996, there was no surface water discharge. Coal ash sluiced to the WAPS was a by-product of the combustion of high-sulfur Illinois coal. CCR fill, consisting primarily of fly ash, bottom ash, and boiler slag is present from approximately 460 feet[1] to a minimum elevation of approximately 440 feet along the west side of the OWAP (**Figure 2-3**). The unit is encompassed by fill deposits of predominantly sand, clay, and silt materials from on-site excavations that were used to construct berms and roads surrounding the various impoundments across the Site.

Water that may come into contact with CCR within the footprint of the WAPS becomes CCR source water. CCR source water samples, collected from the porewater monitoring wells (**Figure 2-4**) screened within the CCR materials at the WAPS were used to provide information for ASDs

[1] All elevations in this report are referenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

and groundwater transport modeling[2]. As a result of declining water levels within the unit post-closure, the remaining porewater monitoring wells have become dry, thus preventing further sample collection.

The Closure and Post-Closure Care Plan, Old West Ash Pond, Old West Polishing Pond at DMG, Hennepin Power Station (Closure Plan) was submitted to IEPA in 2017 [9] and approved by IEPA in a letter dated June 19, 2018. The approved Closure Plan summarized the planned closure of the WAPS, which included dewatering the CCR, if needed, mechanical excavation of material from the OWPP for use as structural fill in the WAPS, grading within the WAPS, constructing an alternate cover system consisting of geomembrane and vegetated cover soils in direct contact with the graded CCR, and establishment of a vegetative cover. Closure construction was completed on November 17, 2020 [10].

2.3 Geology and Hydrogeology

Significant site investigation has been completed at the HPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the WAPS has been well characterized and detailed in the October 25, 2021 operating permit application and the Hydrogeologic Site Characterization Report (HCR) submitted as part of the Closure Plan [4, 11, 9]. Those materials, in addition to data collected from the nearby East Ash Pond System, where representative of Site conditions, are incorporated herein.

2.3.1 Hydrostratigraphic Units

In addition to CCR, materials at the site have been categorized into two hydrostratigraphic units at the WAPS based on stratigraphic relationships, geologic composition, and common hydrogeologic properties. Cross-sections developed for the HCR are included in **Appendix A**. The units, listed from surface downward, are summarized as follows:

- **Uppermost Aquifer (UA)**: Includes the Cahokia Alluvium which consists of fine-grained river deposits comprised of silts and clays (upper UA), fine-medium sands (middle UA), and highly permeable glacial outwash sands and gravels of the Henry Formation (lower UA). The UA contains variable amounts of cobbles and boulders within a sand and gravel matrix. Both the prevalence and size of the cobbles and boulders increase with depth.

- **Bedrock Confining Unit**: Comprised of interbedded layers of shales with thin limestone, sandstone, and coal beds. Representative hydraulic conductivity for shale ranges from 5×10^{-6} to 5×10^{-10} centimeters per second (cm/s) and this unit defines the lower boundary of the UA. Borings along the perimeter of the nearby East Ash Pond System confirm the presence of shale bedrock between elevations ranging from 399.2 to 410.2 feet [12].

2.3.2 Uppermost Aquifer

The unlithified geologic deposits of the UA surrounding the WAPS are derived from recent river deposition, glacial outwash, and glacial tills. The WAPS overlies both glacial outwash deposits (Henry Formation) and alluvium (Cahokia Alluvium). OWAP Pond No. 1 rests on top of lower terrace glacial deposits, and the eastern portion of Pond No. 3 overlies alluvial sand. Whereas the

[2] Per Federal Register 80 (21302), which promulgated the final C.F.R. 40 § 257 rule, porewater concentrations should be used to characterize potential leaching from impoundments. As discussed further in USEPA's risk assessment of CCR surface impoundments (USEPA 2014), porewater is "collected from the interstitial water between waste particles in surface impoundments as it occurs in the field," and concentrations within the porewater are "the most representative data available for impoundments because these data are field-measured concentrations of leachate." Therefore, CCR source water collected from porewater wells screened near the base of ash within the unit represents the CCR source term.

western portion of Pond No. 3 and the OPP overlies silty clay alluvial channel fill deposits (**Figure 2-3**). The total thickness of the UA varies in thickness ranging from 50 to 200 feet. Groundwater monitoring for the UA is focused on the sand and gravel zone because it is continuous, exhibits high groundwater velocities, and is most likely to indicate potential migration of impacts from the WAPS. The top of the sand and gravel portion of the UA is shown on **Figure 2-5**. The sand and gravel is present at the surface at an approximate elevation of 450 feet (no overlying clay/silt) near wells 25, 26, and within 5 feet of the surface at wells 30, 31, 35, and 36. CCR is also near the top of the sand and gravel in eastern areas of the WAPS. From the topographic highs, the top of the sand and gravel slopes downward toward the river to approximately 410 feet near well 21/21R and 51. The direction of groundwater flow and hydraulic gradient is contingent on the elevation of the Illinois River which is directly adjacent to the WAPS.

2.3.3 Regional Bedrock Geology

The bedrock geology near the Hennepin Power Station is primarily comprised of the Pennsylvanian Carbondale Formation, which is characterized by shale with thin limestone, sandstone, and coal beds. The bedrock surface elevation ranges from 400 to 450 feet, with shale bedrock confirmed between elevations of 400 and 410 feet in the vicinity of the WAPS. The thickness of Pennsylvanian rocks varies from 150 to 525 feet across Putnam County and is estimated to be around 300 to 400 feet near the site. Beneath the Pennsylvanian rocks lie Mississippian and Devonian-age interbedded layers of limestone and shale over Silurian-age dolomite, with aquifer depths ranging from less than 1,000 feet to over 1,800 feet. [4].

2.3.4 Water Table Elevation and Groundwater Flow Direction

Measured water table elevations in the UA during the quarterly sampling events in 2023 ranged from approximately 440 feet in the northwest portion of the site (well 34) to approximately 449 feet south of the WAPs in well 26 (**Table 2-1**; **Figure 2-6** to **Figure 2-9**). Increased groundwater elevations measured near the river in wells 22, 34, and 50 during periods of flooding (**Figure 2-5**) indicate there is a potential connection between the river and the sand and gravel of the UA in this area. Groundwater elevations following closure have been relatively stable, generally varying less than approximately 2 feet.

The primary groundwater flow direction within the UA is generally northwest from areas where the sand and gravel in the UA is closest to the surface (wells 25, 26, 30, 31, 35, and 36) toward the river and locations where the UA potentially interacts with the base of the river (*i.e.,* wells 22, 34, and 50).

2.3.4.1 Impact of Surface Water Bodies on Groundwater Flow

Under normal river stage conditions, the Illinois River serves as the primary local and regional receiving body of water for groundwater in the area, with its lowest stage typically occurring between August and October [4]. Historically during this period, a groundwater divide becomes apparent beneath the WAPS, directing flow north towards the river and southwestward, eventually migrating west of the WAPS. Surface water elevations in the Donnelley Wildlife Management Area (DWMA) are expected to be similar to elevations measured in wells 32, 33, and 34. Groundwater flow patterns are depicted in potentiometric surface maps for quarters 1 through 4 of 2023 (**Figures 2-6 through 2-9**), which align with historical observations.

During annual spring flooding from March to June, and sporadic flood events, river stages exceed adjacent groundwater levels, resulting in temporary aquifer recharge and a reversal of groundwater flow direction. Horizontal gradients across the site flatten during these events. A representative potentiometric surface map for February 28 and March 1, 2023 (**Figure 2-6**), illustrates groundwater flow conditions during flood stage, with an approximate river elevation of 449.50 feet. These reversals are temporary and limited in duration and extent. Horizontal hydraulic gradients from the WAPS to off-site areas vary from 0.001 during Illinois River flood stage to about 0.005 during normal river stage.

2.3.5 Hydraulic Conductivities

2.3.5.1 Field Hydraulic Conductivities

Hydraulic conductivity was calculated based on field tests at seven wells in proximity to the WAPS. Hydraulic conductivity ranged from 1.2×10^{-2} cm/s in the Henry Formation (deep UA) to 1.3×10^{-4} cm/s in the Cahokia Alluvium silt (shallowest UA). The geometric mean hydraulic conductivity for the sand and gravel portion of the UA is 6×10^{-3} cm/s. The geometric mean for wells finished in the glacial outwash gravels of the Henry Formation is 1.7×10^{-2} cm/s [4].

A pump test was also performed in the Henry Formation using a "fire well" which resulted in a reported hydraulic conductivity of 1.3×10^{-1} cm/s. The well is located in proximity to the southwest corner of the HPP, east of the WAPS [4].

2.3.5.2 Laboratory Hydraulic Conductivities

Hydraulic conductivity laboratory tests were performed for two samples collected in boring HEN-B010 (fly ash with sand and gravel) near the south berm of Old West Pond 3 and HEN-B017 (gray lean clay with sand) near the west berm of the OWPP. Hydraulic conductivities were calculated to be 1.2×10^{-5} cm/s and 6.8×10^{-7} cm/s, respectively [4].

2.3.5.3 Groundwater Velocity and Vertical Gradients

Hydraulic gradients were calculated from water-level elevations at wells 21 to 34 and wells 27 to 33 in June and September 2013 [4] as representative gradients for the predominant direction of lateral flow at the WAPS. Hydraulic gradients ranged from 0.005 (21 to 34) to 0.001 (27 to 37) during both periods of measurement [4].

Groundwater velocities were calculated using geometric means of the field calculated hydraulic conductivities of 1.7×10^{-2} cm/s (glacial outwash gravels) and 6.0×10^{-3} cm/s (sand and gravel), an effective porosity of 0.22 and the hydraulic gradients listed above. Groundwater velocities calculated in proximity to the WAPS, between wells 21 to 34 and wells 27 to 33, range from 0.03 meters per day (m/day) to 0.34 m/day [4].

Vertical gradients evaluated in wells 22 and 22D in 2023 indicate groundwater generally has an upward gradient in this area, which is consistent with the Illinois River being the receiving water body for regional groundwater. Downward gradients observed in February and November are potentially a result of delayed response to changes in river stage in the deeper well, and a measurement anomaly, respectively (**Figure 2-10**).

2.4 Groundwater Monitoring

The monitoring system for the WAPS is shown on **Figure 2-11** and consists of two background monitoring wells (32 and 34) and nine compliance monitoring wells (21R, 22, 22D, 23, 27, 35, 49, 50, and 51). These monitoring wells are screened within the UA along the perimeter of the WAPS to monitor potential impacts from the SI [13]. During remedial construction performed in February 2020, wells 21 and 24 were abandoned and replaced with wells 21R and 51, respectively. Discussion of historical groundwater data from wells 21 and 24 is presented in **Section 3** of this report and will refer to their respective replacement wells.

2.5 Hydrogeologic Conceptual Site Model

The overall groundwater flow regime within the unlithified materials is consistent with topographically-controlled flow patterns, where infiltration of precipitation recharges groundwater and flows north and west near the site towards the Illinois River. Flow patterns within the site hydrostratigraphic units are typically horizontal, with components of converging vertical (upward) flow near and underneath the river. Under typical post-closure conditions, groundwater flow directions at the OWAP are north, towards the river. During the operation of the impoundments, high local recharge to groundwater from sluicing of CCR created radial flow conditions near the impoundment; while groundwater flow was still predominantly towards the river, some of the groundwater beneath the impoundment flowed towards the adjacent wetlands located south and west of the OWAP.

After sluicing was halted, recharge continued to infiltrate the CCR in the WAPS. The recharge in the footprint of the OWAP migrated within the CCR into the OWPP (through ash within the former western separator berm), and downward into the UA at a reduced rate (since sluice water was no longer present). During closure the OWPP was dewatered, a temporary sheet pile wall was constructed along its eastern side to facilitate the excavation of ash in the OWPP, and a solid clay berm along the west side of the OWAP was constructed. The unit was then closed with a geomembrane cover system to significantly reduce and control infiltration into the CCR material. The sheet pile was left in place at the completion of the construction.

Currently, little to no precipitation enters the remaining CCR in the WAPS due to the geomembrane cover system; however, during high river stage the heads within the UA may become elevated and potentially intersect the base of the CCR. The extent and magnitude of these events is based on the stage of the Illinois River and the duration of the elevated levels.

Conceptually, source water from the WAPS, if present, migrates downward into the materials of the UA, either sand or silt/clay, and mixes with groundwater. Groundwater continues to migrate vertically in the low permeability materials until it encounters the sand and gravel portions of the UA. In the sand and gravel, groundwater migrates horizontally to the north towards the Illinois River, and depending on elevations, may also have a component to the southwest/west which eventually intersects the Illinois River.

Based on the conceptual model discussed above, the compliance wells at the WAPS have been grouped into the following categories based on their location within the flow system (**Figure 2-5**):

- Unconfined UA wells: Monitoring wells located in areas where the sand and gravel unit is near the land surface (wells 22, 22D, 32, 35, 36, 49, and 50). These wells are located on the

eastern half of the unit or southeast of the WAPS. The bottom of the screened intervals are at an elevation greater than 420 feet (except 22D) and the sand and gravel is overlain by less than 8 feet of fine-grained material.

- Transitional UA wells: Monitoring wells within sand and gravel that is overlain by 15 to 25 feet of fine-grained material (wells 23, 27, and 34). The base of the screens are at an elevation between 410 and 420 feet and the wells are located in a "U" shape around the former OWPP.
- Confined UA wells: Wells within sand and gravel at depth below 30 to 40 feet of fine-grained material (wells 21R and 51). These wells are located on the west and northeast side of the OWPP, and the base of the wells are at an elevation below 405 feet.

3. OCCURRENCE AND DISTRIBUTION OF GROUNDWATER EXCEEDANCES (EXTENT)

As described in Section 1, exceedances from sampling events E001, E002, and E003 include the following parameters and wells within the UA:

- Arsenic at 21R and 51
- Boron at 21R, 22, 23, and 35
- Sulfate at 23 and 35
- Lithium at 22
- TDS at 35

The extents of exceedances discussed below were defined using existing monitoring wells, including wells present onsite (**Table 3-1**) that may not be included in the 35 I.A.C. § 845 monitoring program.

3.1 Additional Investigation to Further Evaluate Nature and Extent

Solid phase data were collected and evaluated to assess potential geological sources of exceedance parameters and to inform the GCSM (discussed further in **Section 4**). Solid phase data were not collected from the CCR source material prior to completion of closure of the unit in 2020. A total of three borings were advanced adjacent to locations with potential exceedances (wells 22 and 51), and background well (34). Four solids samples were collected and analyzed for the following:

- EPA 6010B for 7-step sequential extraction (iron, aluminum, arsenic, manganese, lithium, and boron);
- EPA 6010B for Total Metals (35 I.A.C. § 845.600 parameters [minus radium] plus aluminum, bismuth, copper, iron, magnesium, manganese, nickel, potassium, silver, strontium, tin, titanium, uranium, vanadium, yttrium, and zinc) via Bulk Characterization;
- Bulk Mineralogy by Reitveld x-ray diffraction analysis;
- Sulfate and Sulfide Analysis via anion chromatography;
- Total Organic Carbon Analysis; and,
- Loss on Ignition Analysis.

In addition, fifteen surface water samples were collected to characterize the water quality in the Illinois River upgradient and adjacent to the WAPS (**Figure 3-1**). Surface water samples were analyzed for dissolved (*i.e.*, filtered) fractions of arsenic, lithium, and boron, and total (*i.e.*, unfiltered) sulfate. Data from this investigation is presented in **Table 3-2** and has been incorporated into this report where applicable.

3.2 Extents in the Uppermost Aquifer

Exceedances are identified quarterly following comparison of lower confidence limits (LCLs) to the GWPSs described in 35 I.A.C. § 845.600. The LCLs vary as the dataset is updated to include additional quarterly events (**Table 3-3**). The discussion below includes ranges of concentrations

measured in wells with exceedances, because there is no single value for LCLs. The statistical results from the three compliance monitoring events are presented in **Table 3-3** and all data evaluated has been summarized in **Table 3-4**.

3.2.1 Arsenic

Arsenic concentrations in monitoring wells 21R and 51 resulted in exceedances of the GWPS (0.010 milligrams per liter [mg/L], **Figure 3-2**). The concentrations and extent of arsenic exceedances at the WAPS are summarized as follows:

- 21R and 51 – Exceedances were reported in all three compliance sampling events. Data collected between 2015 and 2023 reported arsenic concentrations ranging from 0.0024 to 0.0345 mg/L in well 21/21R and from 0.0102 to 0.038 mg/L in well 24/51 (**Table 3-4**). The lateral extent of elevated arsenic concentrations are defined by adjacent monitoring wells 34 (non-detect to 0.0005 mg/L) located west of 21R, and 23 (non-detect to 0.0005 mg/L), located east of 51 (**Figure 2-11**, **Table 3-4**). The downgradient extent is defined by the Illinois River, where arsenic concentrations measured in 2020 at sample locations IR04-C/L/R and IR05-C/L/R were all less than 0.0031 mg/L (**Table 3-2).** Surface water samples of the Illinois River upgradient, midgradient, and downgradient of the HPP were indistinguishable for arsenic concentrations, indicating that there is no measurable impact to the Illinois River from groundwater relative to the WAP or HPP. Downward vertical migration of arsenic concentrations above the GWPS is limited by regional upward gradients to the Illinois river, as observed in wells 22/22D.

3.2.2 Boron

Boron concentrations in monitoring wells 21R (E001 only), 22, 23, and 35 resulted in exceedances of the GWPS (2 mg/L, **Figure 3-2**). The concentrations and extent of boron exceedances at the WAPS are summarized as follows:

- 21R (E001 only) – The concentrations of boron in 21/21R ranged from 1.25 to 4.60 mg/L (**Table 3-4**) and LCLs have declined between events E001 and E003. The lateral extent of elevated boron concentrations are defined by adjacent monitoring wells 34 (0.075 to 0.206 mg/L) located west of 21R, and 24/51 (1.3 to 3.84 mg/L), located east of 21R (**Figure 2-11**, **Table 3-4**).
- 22 – Concentrations of boron in monitoring well 22 range from 0.13 to 6.72 mg/L (**Table 3-4**) and LCLs have declined between events E001 and E003. Concentrations above the GWPS are defined laterally by well 49 (0.68 to 1.70 mg/L) located west of 22, and by well 50 (0.59 to 1.43 mg/L) located east of well 22 (**Table 3-4**). Vertical extent of boron concentrations above the GWPS is defined by nested well 22D (1.63 to 2.68 mg/L).
- 23 – Concentrations of boron range in well 23 from 5.63 to 12.8 mg/L (**Table 3-4**) and LCLs are variable during events E001 through E003. The extent of boron concentrations above the GWPS is defined laterally by well 51 (1.30 to 3.14 mg/L) to the west and well 49 (0.68 to 1.70 mg/L) to the east.
- 35 – Concentrations of boron in well 35 range from 4.98 to 18.1 mg/L (**Table 3-4**) and LCLs have declined during events E001 through E003. The extent of elevated boron concentrations is defined in the downgradient direction of flow (towards both 23 and 27) by concentrations measured in well 27 (2.00 to 4.31 mg/L) and the Illinois River (discussed below).

The extent of boron concentrations above the GWPS downgradient from all locations is defined by the results of surface water sampling from the Illinois River completed in 2020 (**Figure 3-1**). Concentrations of boron measured at sample locations IR04-C/L/R and IR05-C/L/R were all less than 0.14 mg/L. Surface water samples of the Illinois River upgradient, midgradient, and downgradient of the HPP were indistinguishable for boron concentrations, indicating that there is no measurable impact to the Illinois River from groundwater relative to the WAP or HPP. Downward migration of boron concentrations within the UA is limited by the presence of regional upward gradients to the Illinois River, as observed in wells 22/22D.

3.2.3 Lithium

Lithium concentrations in monitoring well 22 resulted in the only exceedance of the GWPS (0.04 mg/L, **Figure 3-2**). The concentrations of lithium within well 22 range from 0.0090 to 0.0764 mg/L (**Table 3-4**) and LCLs have increased during events E001 through E003 as concentrations stabilize. The extent of lithium concentrations above the GWPS is defined laterally by well 50 (0.0071 to 0.0300 mg/L) to the east and well 49 (0.0202 to 0.0297 mg/L) to the west. Surface water samples collected from the Illinois River in 2020 (**Figure 3-1**) at sample locations IR04-C/L/R and IR05-C/L/R had lithium concentrations below 0.008 mg/L. Surface water samples of the Illinois River upgradient, midgradient, and downgradient of the HPP were indistinguishable for lithium concentrations, indicating that there is no measurable impact to the Illinois River from groundwater relative to WAP or HPP. The vertical extent of lithium is defined by concentrations measured in well 22D which are below the GWPS, ranging from 0.0123 to 0.0190 mg/L (**Table 3-4**).

3.2.4 Sulfate

Sulfate concentrations in monitoring wells 23 and 35 resulted in exceedances of the GWPS (400 mg/L, **Figure 3-2**). The concentrations and extent of sulfate exceedances at the WAPS are summarized as follows:

- 23 – Concentrations of sulfate range from 323 to 554 mg/L and LCLs exhibit no trend during events E001 through E003. The extent of sulfate concentrations above the GWPS, like boron, is defined by well 24/51 (87.0 to 162 mg/L) to the west and well 49 (71.0 to 114 mg/L) to the east (**Table 3-4**).
- 35 – Concentrations of sulfate in well 35 range from 255 to 1,190 mg/L and LCLs have increased during events E001 through E003. The extent of elevated sulfate concentrations is defined in the downgradient direction of flow (towards both 23 and 27) by well 27 (104 to 228 mg/L) and the Illinois River.

Surface water samples collected from the Illinois River in 2020 (**Figure 3-1**) at sample locations IR04-C/L/R and IR05-C/L/R had sulfate concentrations ranging from 73 to 75 mg/L. Surface water samples of the Illinois River upgradient, midgradient, and downgradient of the HPP were indistinguishable for sulfate concentrations, indicating that there is no measurable impact to the Illinois River from groundwater relative to WAP or HPP. The vertical migration of sulfate is limited by the regional upward gradients near the Illinois River, as observed onsite in wells 22 and 22D.

3.2.5 Total Dissolved Solids

TDS results indicate the mass of dissolved material in groundwater and is a representation of multiple constituents present in the groundwater. Typically, major ions (such as sulfate) represent the primary contributors to TDS. TDS detected in monitoring well 35 resulted in an

exceedance of the GWPS (1200 mg/L, **Figure 3-2**). This TDS exceedance is coincident with the sulfate exceedance observed at well 35. The concentrations and extent of TDS exceedances at the WAPS are defined downgradient of well 35 by wells 23, 27, 49, and 51 (**Table 3-4**).

The vertical migration of TDS is limited by the regional upward gradients near the Illinois River, as observed onsite in wells 22 and 22D.

4. GEOCHEMICAL CONCEPTUAL SITE MODEL (NATURE)

A GCSM was developed to describe the conditions of the groundwater in the vicinity of the HPP WAPS and is summarized here (full analysis presented in **Appendix B**). The GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. Only parameters that have exceeded the GWPS in WAPS groundwater, to be addressed in the corrective action plan, are included in the GCSM. As discussed in previous sections the exceedances observed at the WAPS include arsenic, boron, lithium, sulfate, and TDS.

The CCR materials are the primary source of constituent loading to the CCR porewater (*i.e.*, CCR source water). Over an extended period (*e.g.*, months to years), the CCR source water (*i.e.*, water contained within the interstitial pore spaces of the CCR that can be sampled by low-flow groundwater sampling methods) reaches equilibrium with the CCR materials. The porewater is therefore representative of the mobile phase constituents capable of migrating into the underlying materials and potentially downgradient in groundwater. The WAPS CCR source water is therefore the primary indicator of constituents *available* to the groundwater and is considered as the primary source term for environmental investigation and fate and transport modeling.

Arsenic, boron, lithium, and sulfate are naturally present in coal deposits and are concentrated in CCR. TDS is a measure of inorganic and organic substances in solution and, as such, TDS trends are generally consistent with those of major ions in the WAPS groundwater system. Arsenic, boron, and lithium were identified in UA solids adjacent to downgradient and background wells, which suggests that aquifer solids could provide a secondary natural geogenic source of arsenic, boron, and lithium to the groundwater. Redox conditions vary across the site, with more oxidizing conditions on the east side of the WAPS and more reducing conditions on the west. Reducing conditions may be enhancing arsenic mobility and thus aqueous arsenic concentrations at select wells on the west of the WAPS. The principal source of arsenic, boron, lithium, sulfate, and TDS exceedances to groundwater of the UA is currently expected to be the WAPS CCR porewater.

Arsenic, boron, lithium, and sulfate in the groundwater system may be attenuated via surface complexation reactions with metal (*i.e.*, aluminum, iron, and manganese) oxyhydroxides. Iron oxides were detected in aquifer solids and are generally predicted to be stable at monitoring wells across the monitoring system. Clay minerals were also identified in aquifer solids and may provide an additional attenuation mechanism for arsenic, boron, lithium, and sulfate in groundwater. At the limited locations across the monitoring system where reducing conditions are present, microbial sulfate reduction may also contribute to decreased sulfate concentrations in the groundwater. Attenuation of the constituents contributing to TDS, such as sulfate, will reduce TDS concentrations as well.

5. COMBINED GEOCHEMICAL AND HYDROGEOLOGIC CONCEPTUAL SITE MODELS

5.1 Arsenic Conceptual Site Model

The conceptual site model (CSM) describing current conditions at the WAPS combining the hydrogeologic and geochemical CSMs for arsenic is as follows. Water that may come into contact with CCR in the WAPS becomes porewater within the unlined CCR unit. During operations, sluicing of CCR with elevated heads in the unit resulted in radial flow, likely causing porewater, potentially impacted with arsenic, to migrate downward into the UA. In the UA, porewater mixes with groundwater and the resulting geochemical conditions influence the mobility of arsenic and concentrations observed in compliance wells. In the unconfined/oxidizing portions of the UA, arsenic concentrations do not exceed the GWPS, while in the deeper confined portions of the UA, reducing concentrations result in elevated arsenic concentrations that exceed the GWPS. In addition to physical attenuation mechanisms of dilution and dispersion, elevated arsenic concentrations may be attenuated via surface complexation reactions with metal (*i.e.,* aluminum, iron, and manganese) oxyhydroxides or reactions with clay minerals.

5.2 Boron Conceptual Site Model

The CSM describing current conditions at the WAPS combining the hydrogeologic and geochemical CSMs for boron is as follows. Water that may come into contact with CCR in the WAPS becomes porewater within the unlined CCR unit. During operations, sluicing of CCR with elevated heads in the unit resulted in radial flow, likely causing porewater, impacted with boron, to migrate downward and outward into the UA. In the UA, porewater mixes with groundwater and migrates toward the Illinois River. After sluicing operations ceased in 1996 boron concentrations began to decline in all wells (except 23 and 35) and continued on that trajectory following closure of the unit in 2020. The reduction in infiltration has generally resulted in lower boron concentrations and small shifts in groundwater flow directions (*i.e.,* boron concentrations in well 27 have declined and no longer exceed the GWPS). At well 35 (and 23, which is downgradient of 35), localized flow conditions following closure appear to be influencing boron concentrations at this location while head within the WAPS approaches equilibrium. The Hydrologic Evaluation of Landfill Performance (HELP) model completed for closure indicated that hydrostatic equilibrium would be achieved in approximately 7 years following closure (or approximately 2027) [14]. In addition to physical attenuation mechanisms of dilution and dispersion, elevated boron concentrations may be attenuated via surface complexation reactions with metal (*i.e.,* aluminum, iron, and manganese) oxyhydroxides or reactions with clay minerals.

5.3 Lithium Conceptual Site Model

Similar to arsenic and boron CSMs, water that may come into contact with CCR in the WAPS becomes porewater within the unlined CCR unit. During operations, sluicing of CCR with elevated heads in the unit resulted in radial flow, likely causing porewater, potentially impacted with lithium, to migrate downward into the UA. In the UA, porewater mixes with groundwater and the resulting geochemical conditions influence the concentrations observed in compliance wells. Lithium concentrations are above the GWPS only in well 22 at the WAPS. The well is located north of the CCR unit and is the only compliance location directly downgradient of the CCR unit without a clay/silt layer above the well screen. In addition to physical attenuation mechanisms of dilution and dispersion, elevated lithium concentrations may be attenuated via surface

complexation reactions with metal (*i.e.,* aluminum, iron, and manganese) oxyhydroxides or reactions with clay minerals. The lack of clay at this location may have resulted in migration of lithium to this location and observations following closure indicate concentrations are declining.

5.4 Sulfate and TDS Conceptual Site Model

Consistent with the other CSMs, water that may come into contact with CCR in the WAPS becomes porewater within the unlined CCR unit. During operations, sluicing of CCR with elevated heads in the unit resulted in radial flow, likely causing porewater, impacted with sulfate, to migrate downward and outward into the UA. In the UA, porewater mixes with groundwater and migrates toward the Illinois River with concentrations attenuating due to physical mechanisms (dilution and dispersion), and potentially through surface complexation reactions with metal (*i.e.*, aluminum, iron, and manganese) oxyhydroxides or reactions with clay minerals. Under sufficient reducing conditions, microbial sulfate reduction may also contribute to decreased sulfate concentrations in the groundwater. After sluicing operations ceased in 1996 sulfate concentrations began to decline in all wells (except 23 and 35) and continued on that trajectory following closure of the unit in 2020. The reduction in infiltration has generally resulted in lower sulfate concentrations and small shifts in groundwater flow directions. At well 35 (and 23, which is downgradient of 35), localized flow conditions following closure appear to be influencing sulfate concentrations at this location while head within the WAPS approaches equilibrium. The HELP model completed for closure indicated that hydrostatic equilibrium would be achieved in approximately 7 years following closure (or approximately 2027) [14] . Lack of elevated sulfate (while boron persists) at UA well 21R provides evidence that sulfate reduction may be occurring.

6. CONCLUSIONS AND FUTURE ACTIVITIES

In accordance with 35 I.A.C. § 845.650(d)(1), the nature and extent of GWPS exceedances of arsenic, boron, lithium, sulfate, and TDS have been described in sufficient detail to support a complete and accurate assessment of the corrective measures necessary to effectively clean up all releases from the WAPS. As discussed in Sections 3.3.1 and 3.3.2, the horizontal delineation of all constituents has been defined by a combination of results at existing wells and surface water results that indicate concentrations are below the GWPS.

Following closure, groundwater monitoring results are generally consistent with the conclusions in the Closure Plan [9] and site conditions are improving as follows:

- Water levels within the CCR are declining. Porewater monitoring wells have gone dry, indicating the level in the unit has declined.
- Trends for boron and sulfate (**Appendix B** [GCSM]), which are conservative indicators of CCR impacts, indicate concentrations are declining in all wells except wells 23 and 35. Concentrations at these two locations are potentially related to localized flow conditions that originated as a result of closure, but are expected to dissipate as the unit reaches equilibrium (predicted to occur in 2027).

These observations are consistent with the conceptual site models and constituent extents provided in **Section 5.**

Boron was selected for modeling source control presented in the Final Closure Plan, as described in the Groundwater Model Report (GMR) [14]. Boron is considered a surrogate parameter for arsenic, lithium, sulfate and TDS because it is the constituent at the site that will likely require the longest time to achieve the GWPS. Further modeling selected constituents is a common industry approach for evaluation of environmental systems and is sufficient to achieve the modeling objectives in support of the closure alternatives analysis [15]. Ongoing groundwater modeling, which includes recent data following closure and is expected to be completed in 2025, indicates that the GWPS will be met approximately 30 years after the initiation of groundwater polishing (which starts when the Corrective Action Plan permit is issued). Additional geochemical modeling will be completed to evaluate how surface complexation reactions with metal oxyhydroxides and clay minerals or changes in redox conditions may affect arsenic, boron, lithium, and sulfate mobility or in the case and therefore the time to reach the GWPS for these parameters.

1. EXECUTIVE SUMMARY

This report documents the development of a geochemical conceptual site model (GCSM) to describe conditions at the Hennepin Power Plant (HPP) West Ash Pond System (WAPS) coal combustion residuals (CCR) unit (Unit #804). A GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the subsurface soil and groundwater environment. The GCSM was prepared in support of an evaluation of the nature and extent (N&E) of exceedances of constituents of concern (COCs) above the groundwater protection standards (GWPS) at the WAPS. Through the second, third, and fourth quarters of 2023, COC exceedances of arsenic, boron, lithium, sulfate, and total dissolved solids (TDS) were reported at WAPS compliance wells. The exceedances occur exclusively in the uppermost aquifer (UA), which consists of fill, unconsolidated alluvium, and Pleistocene-age glacial outwash and till deposits.

The CCR materials are the primary source of constituent loading to the CCR porewater (i.e., CCR source water). Over an extended period (e.g., months to years), the CCR source water (i.e., water contained within the interstitial pore spaces of the CCR that can be sampled by low-flow groundwater sampling methods) reaches equilibrium with the CCR materials. The porewater is therefore representative of the mobile phase constituents capable of migrating into the underlying materials and potentially downgradient in groundwater. The WAPS CCR source water is therefore the primary indicator of boron and sulfate *available* to the groundwater and is considered as the primary source term for environmental investigation and fate and transport modeling.

Arsenic, boron, lithium, and sulfate are naturally present in coal deposits and are concentrated in CCR. TDS is a measure of inorganic and organic substances in solution and, as such, TDS trends are generally consistent with those of major ions in the WAPS groundwater system. Arsenic, boron, and lithium were identified in UA solids adjacent to downgradient and background wells, which suggests that aquifer solids could provide a secondary natural geogenic source of arsenic, boron, and lithium to the groundwater. Redox conditions vary across the site, with more oxidizing conditions on the east side of the WAPS and more reducing conditions on the west. Reducing conditions may be enhancing arsenic mobility and thus aqueous arsenic concentrations at select wells on the west of the WAPS. The source of arsenic, boron, lithium, sulfate, and TDS to groundwater of the UA is currently expected to be the WAPS CCR porewater.

Arsenic, boron, lithium, and sulfate in the groundwater system may be attenuated via surface complexation reactions with metal (i.e., aluminum, iron, and manganese) oxyhydroxides. Iron oxides were detected in aquifer solids and are generally predicted to be stable at monitoring wells across the network. Clay minerals were also identified in aquifer solids and may provide an additional attenuation mechanism for arsenic, boron, lithium, and sulfate in groundwater. At the limited locations across the network where reducing conditions are present, microbial sulfate reduction may also contribute to decreased sulfate concentrations in the groundwater. Attenuation of the constituents contributing to TDS, such as sulfate, will reduce TDS concentrations as well.

2. INTRODUCTION

This report documents the development of a geochemical conceptual site model (GCSM) to describe conditions at the Hennepin Power Plant (HPP) West Ash Pond System (WAPS) coal combustion residuals (CCR) unit (Unit #804). A GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the subsurface soil and groundwater environment. The GCSM was prepared in support of an evaluation of the nature and extent (N&E) of exceedances of constituents of concern (COCs) above the groundwater protection standards (GWPS) at the WAPS. This document has been prepared as an appendix to the HPP WAPS N&E Report prepared by Ramboll Americas Engineering Solutions, Inc. (Ramboll). Parameters with exceedances above the GWPS at the HPP WAPS compliance wells for the second, third, and fourth quarters of 2023 (Q2 2023, Q3 2023, and Q4 2023) sampling events completed under Illinois Administrative Code (I.A.C.) Title 35 Section 845.630 include arsenic, boron, lithium, sulfate, and total dissolved solids (TDS). Arsenic exceedances were observed at compliance wells 21R and 51. Boron exceedances were observed at compliance wells 21R, 22, 23, 35, and 27. Lithium was an exceedance at compliance well 22, and sulfate exceedances were observed at compliance wells 23 and 35. TDS exceeded the GWPS at compliance well 35. The exceedances identified at the WAPS occur exclusively in the uppermost aquifer (UA), the only monitored unit at the WAPS.

An exceedance of cadmium was observed at compliance monitoring well 22 during the Q2 2023 sampling event. However, an alternative source demonstration (ASD), as allowed by I.A.C. 845.650(e), was completed for the cadmium exceedance (Ramboll 2023). The cadmium ASD was accepted by the Illinois Environmental Protection Agency (IEPA) on December 7, 2023 (IEPA 2023); therefore, cadmium is not included as a COC in this GCSM.

3. SITE BACKGROUND

3.1 Site Overview

An overview of site characteristics and hydrogeology is presented in the HPP WAPS N&E Report. A site layout figure is provided in Attachment A.[1] The Hennepin WAPS consists of the Old West Ash Pond (OWAP) (Ponds No. 1 and No. 3) and the Old West Polishing Pond (OWPP). Pond No. 1 of the OWAP was constructed in 1951 and 1952, and Pond No 3. was constructed in 1968. Ponds No. 1 and No. 3 comprising the OWAP were merged in 1988 and 1989 when the embankment surrounding OWAP was raised. The OWPP was also constructed during this time (1988-1989). The WAPS operated between 1952 to 1996, and closure occurred between August 2019 and November 2020. The OWPP was closed by removal and consolidation of the CCR into OWAP, and subsequently, the OWAP was closed with a geomembrane and vegetated soil cover. A steel sheetpile wall was installed between the OWAP and the OWPP during closure as a temporary support-of-excavation feature to facilitate CCR consolidation and a compacted clay dike was constructed in front of the steel sheet pile wall to provide a permanent and continuous earthen containment system around the consolidated WAPS. The steel sheetpile was left in place following closure of the unit.

The Hennepin WAPS is located west of the HPP and adjacent to the Illinois River. The HPP property is bordered by farm fields to the east and south, low lying floodplains to the west, and the Illinois River to the north.

A Hydrogeologic Site Characterization Report (NRT 2017) and a Hydrogeologic Monitoring Plan (OBG 2017) previously described the hydrostratigraphic units (HSUs) present in the vicinity of the Hennepin WAPS. These reports indicate that the subsurface stratigraphy of the WAPS consists of fill, unconsolidated alluvium, and Pleistocene-age glacial outwash and till deposits, which comprise the UA. Sand and gravel deposits are thicker underneath the eastern portion of the WAPS, while the western portion is underlain by less permeable, silty and clay material (OBG, 2017). The UA may be up to 130 feet thick beneath the WAPS and is underlain by Pennsylvanian-age shale bedrock with interbedded limestone, sandstone, and coal seams.

3.2 Groundwater Monitoring Network

A groundwater monitoring network was proposed in accordance with I.A.C. Title 35 Section 845.630 to monitor groundwater quality which passes the waste boundary as part of the Operating Permit application to IEPA for the WAPS. The proposed groundwater monitoring network is

[1] This figure is also provided as Figure 2-2 of the HPP WAPS N&E Report.

described in the Addendum to the Groundwater Monitoring Plan (Ramboll 2021) and shown in Attachment B.[2] Well construction information is provided in Attachment C.[3]

Groundwater flow beneath the WAPS within the UA is predominantly to the north and northwest, towards the Illinois River, although the flow direction varies with the elevation of the river. During a high river stage, the groundwater flow direction may reverse, saturating the ash in the OWAP (NRT 2017; NRT 2018). There are localized flow conditions near the south boundary of the WAPS (near compliance well 35) as a result of the elevation of the top of the sand and gravel portion of the UA at this location, continuity of the silt and clay underlying the WAPS, and the presence of drainage features and wetlands south of the unit. A detailed discussion of the hydrogeology of the Site is presented in Section 2 of the HPP WAPS N&E Report.

[2] This figure is also provided as Figure 2-10 of the HPP WAPS N&E Report.
[3] This table is also provided as Table 3-1 of the HPP WAPS N&E Report.

4. GEOCHEMICAL SITE CONDITIONS

4.1 Constituent Transport and Fate

As described in Section 2 and the HPP WAPS N&E Report, arsenic, boron, lithium, sulfate, and TDS exceeded the GWPS at the HPP WAPS. These constituents are frequently present and detectable in CCR porewater and groundwater impacted by CCR.

Arsenic speciation in groundwater is dependent on both pH and oxidation/reduction reactions and is typically present as arsenic (III) or arsenic (V) in environmental systems. Arsenic (III) is the predominant species under relatively reducing conditions and, a pH values less than 9 standard units (SU), forms the neutral complex $As(OH)_3$. Arsenic (V) is the predominant species under relatively oxidizing conditions and typically exists as $HAsO_4^{2-}$ at pH values above 7 SU. Arsenic (V) is more likely to be attenuated than neutral arsenic (III) species due to its negative charge and electrostatic interactions with soil/aquifer solids. In general, arsenic has a high sorption affinity for metal (i.e., aluminum, iron, and manganese) oxyhydroxides and may also sorb to clay minerals (Rahman et al. 2019, Nguyen et al. 2021). Arsenic sorption is typically highest at lower pH values where favorable electrostatics enhance attenuation, and also under oxidizing conditions due to the greater propensity for attenuation of the negatively charged $HAsO_4^{2-}$ species relative to neutral $As(OH)_3$ species. Further, the presence of divalent cations (such as calcium [Ca^{2+}]) can promote arsenic (V) absorption (Nguyen et al. 2021).

Boron is primarily present in groundwater as boric acid (H_3BO_3) or borate ($B[OH]^{4-}$) (Bolan et al. 2023). The speciation of boron depends on pH: at pH below 9.2 standard units (SU), H_3BO_3 is the dominant species (NCBI 2024a). Boron is not subject to oxidation/reduction reactions (Lemarchand et al. 2015; Bolan et al. 2023). Boron primarily adsorbs to positively charged sites on solid metal oxide phases, including iron and aluminum oxides (Goldberg and Glaubig 1985; Bolan et al. 2023). Boron sorbs most extensively to amorphous metal oxides between pH 7 SU and 8 SU (Goldberg and Glaubig 1985). Boron can also sorb onto natural organic substances such as humic acids or coal under favorable conditions, most extensively between pH 8 and 10 SU (LeMarchand et al. 2015). Clay minerals have been correlated with boron sorption in soils (Goldberg 1997), with this sorption mechanism presenting an additional potential attenuation mechanism for boron under certain geochemical conditions.

Lithium in solution is typically conservative. Lithium is more hydrated than other similarly charged cations, which reduces its ability to bind to soil colloids (Robinson et al. 2018, Elbana and Osman 2023). Lithium in groundwater may adsorb to iron and manganese oxides and clay minerals, though retention is often weak, and sorption may decrease with increasing lithium concentrations and/or decreasing pH (Robinson et al. 2018, Elbana and Osman 2023; Steinhoefel et al., 2021). However, lithium sorbed to secondary clays may be incorporated deeper into the mineral matrix for more permanent immobilization (Li and Liu, 2020; Steinhoefel et al., 2021).

Sulfate is the primary form of oxidized sulfur (S(VI)) in the environment and is a divalent oxyanion at pH values greater than 2 SU (Stumm and Morgan 1996). Sulfate in groundwater may adsorb onto positively charged sites on solid metal oxide phases, most commonly iron and manganese oxides (Brown et al. 1999). The extent and strength of sulfate adsorption to metal oxide surfaces depends on pH, ionic strength, and oxide surface area available for sorption. Sulfate can also form insoluble complexes such as barite ($BaSO_4$) (NCBI 2024b). Sulfate in groundwater may be reduced to elemental sulfur (S[0]) or sulfide (S[-II]) under sufficiently reducing conditions, a process governed by local microbial communities (Stumm and Morgan 1996). Generally, reduced sulfur is less mobile in groundwater than sulfate. Reduced sulfur readily precipitates as metal sulfides and adsorbs to solid phases such as iron and manganese oxides (Stumm and Morgan 1996).

TDS is a measure of the mass of dissolved material in water, rather than a specific chemical constituent. Individual constituent contributions to TDS depend on both the concentration and molar mass of each contributor. Typically, major ions (i.e., calcium, sodium, magnesium, potassium, chloride, sulfate, and carbonate species) represent the primary contributors to TDS. As such, TDS is often positively correlated with electrical conductivity and ionic strength (Rusydi 2018, Ghalib et al. 2020). TDS concentrations can be reduced by the removal from aqueous phases of the individual constituents that contribute to TDS.

4.2 Site Solids Characterization

Solid phase data were not collected from the CCR source material prior to completion of unit closure with a geomembrane cover system in 2020.

Site solids were characterized to determine the type and abundance of minerals present in the UA, their geochemical properties, and their effect on the aqueous geochemistry of the groundwater system. Solids were characterized using a variety of analytical techniques, the results of which are presented in Tables 1 to 4. Aquifer solids were collected from three locations within the UA adjacent to existing wells in the WAPS monitoring network:

- SB-22, located downgradient of the WAPS to the northeast adjacent to well 22. Solids were collected from two intervals within the UA (26-27 feet below ground surface [ft bgs] and 29-30 ft bgs). Exceedances of boron and lithium above the GWPS were first observed at well 22 during the Q2 and Q3 2023 statistical evaluations, respectively.

- SB-34, adjacent to background well 34, which is unimpacted by the WAPS. Solids were collected from one interval within the UA (32-33 ft bgs).

- SB-51, located downgradient and northwest of the WAPS adjacent to well 51. Solids were collected from one interval within the UA (42-43 ft bgs). An exceedance of arsenic above the GWPS was first observed at well 51 during the Q2 2023 statistical evaluation.

The monitoring well locations are shown in Attachment B. Boring logs for these locations are provided in Attachment D.

4.2.1 Total Organic Carbon, Loss on Ignition, Sulfate, and Sulfide

Total organic carbon (TOC) represents only the carbon component of organic matter within a solid material, while loss on ignition (LOI) represents the combustible portions of a solid material and is often used as an approximation of organic matter in a sample. The TOC and LOI values for aquifer solids from SB-22, SB-34, and SB-51 are presented in Table 1. TOC values range from 0.34 to 4.6 percent weight [% wt] and LOI values vary from 11.6 to 21.5% wt, indicating that the aquifer solids contain a moderate amount of organic matter. Solids adjacent to well 51 generally contained a higher proportion of organic matter compared to wells to the east based on the LOI results.

Sulfate, as measured in solid leachate after HCl digestion, and sulfide, as measured by combustion-infrared absorption after digestion, were also quantified for the aquifer solids. Observed concentrations of sulfate were below detection (0.1%) in the samples (see Table 1). Total sulfide ranged from below the detection limit (0.04%) at SB-22 (26-27 ft bgs) to 0.18% at SB-51. The presence of sulfides may indicate that sulfate reduction is actively occurring, particularly at well 51 which has reducing conditions (as discussed in Subsection 4.3.2). The laboratory analytical results for TOC, LOI, sulfate, and sulfide are available in Attachment E.

4.2.2 Total Metals via Bulk Characterization

Total metals were analyzed to determine the major and trace metal content of the aquifer solids with results presented in Table 2. The laboratory analytical results are available in Attachment E. Arsenic, boron, and lithium were detected in solids adjacent to wells 22, 34 and 51. The solids from SB-22 had the highest arsenic concentrations while solids from SB-34 (background) and SB-51 had comparable arsenic concentrations (though of these two, only well 51 has an arsenic exceedance in groundwater). Lithium and boron concentrations were both highest in the solids from SB-51. Total iron concentrations were relatively low in aquifer solids sampled from the three wells, with values ranging from 9,400 to 14,000 micrograms per gram (µg/g). Similarly, total manganese concentrations were also relatively low, with values ranging from 220 to 350 µg/g. Both iron and manganese were highest in the aquifer solids from SB-51. Aluminum was also present in the solids from the three wells, with the highest value (8,200 µg/g) at SB-51. The presence of these metals (aluminum, iron, and manganese) in the aquifer solids may provide potential attenuation sites for COCs in the form of metal oxyhydroxides.

4.2.3 Sequential Extraction Procedure Analysis of Metals

A sample of composited material from each boring location was submitted to SGS Canada Inc. (Lakefield, ON, CA) for sequential extraction procedure (SEP). SEPs are chemical extractions used to dissolve metals from specific solid-associated phases. SEPs use progressively stronger reagents to solubilize metals from increasingly recalcitrant phases. Although these procedures do not quantitatively identify the specific metal phases in a soil/aquifer matrix, they do provide a

means to evaluate the class of solids and relative stability in relation to oxidation/reduction (redox) potential and pH fluctuations (Tessier et al. 1979, Kuo et al. 1983, Sposito et al. 1984, Hickey and Kittrick 1984, Gruebel et al. 1988). Therefore, SEP data are useful to interpret the mechanism and potential reversibility of attenuation processes. The 6-step extraction procedure is briefly described, and the results of the SEP analysis are provided in Table 3 and Attachment F.

Manganese was primarily detected in fractions associated with carbonates, iron and manganese oxides, and residual metals, with lesser amounts bound to organic material. Between 8.8% and 25.5% of the iron extracted from the aquifer solids was associated with metal oxide phases, indicating that iron oxides are present at significant concentrations and may provide potential sorption sites for COCs. Arsenic in aquifer solids from SB-34 (background) and SB-51 were bound to the fraction associated with iron and manganese oxides at similar concentrations (0.8 and 0.9 µg/g [29.6% and 25%], respectively). This suggests that iron and manganese oxides in the solids have some capacity to serve as adsorption sites for arsenic and that arsenic may be naturally present in background. Lithium was only identified in association with the residual fraction, which could indicate incorporation into clay minerals. While boron was largely identified in association with the residual fraction, some portion (6.7 to 16.7%) was also identified in the fraction associated with metal oxides (Table 3). SEP data indicated that there was little association of arsenic, boron, and lithium to organics. Overall, these results suggest some attenuation via interaction with metal oxides may be feasible in the aquifer.

4.2.4 Mineralogical Analysis

X-Ray diffraction (XRD) with Rietveld refinement was conducted for identification of minerals in aquifer solid samples. XRD is an analytical technique that provides information about the identity of the crystalline material within a sample but does not provide information about non-crystalline or amorphous phases. XRD results are normalized to 100% of the total weight, meaning that material not characterized by XRD is ignored in the percent calculation. The four samples analyzed by XRD were determined to be primarily composed of quartz (SiO_2), ranging from 33.1 to 57.0 percent by weight (wt%) of the minerals present (Table 4; Attachment G). The second most abundant mineral was either dolomite (ranging from 11.4 to 14.4 wt% in SB-22) or calcite (11.1 wt% in well 34; 20.9 wt% in SB-51), both of which are carbonate minerals. These results are consistent with the field observations documented in the boring logs provided in Attachment D.

Magnetite, which is a mixed valence iron oxide, was identified in the aquifer solids from 0.2 to 0.5 wt%. Magnetite contains both ferrous (2+) and ferric (3+) forms of iron and is therefore considered to be one of the more stable iron oxide minerals in the environment (Cornell and Schwertmann 2003). Magnetite provides adsorption sites to attenuate constituents in solution. Magnetite concentrations do not correlate well with observations of total iron in the solids (i.e., samples with higher iron concentrations do not necessarily have higher abundances of iron oxides minerals as identified in the XRD results). This may be related to the presence of non-crystalline, amorphous iron oxides that are not detected by XRD (described above), which provide additional adsorption capacity in the aquifer.

The aquifer solids samples also had measurable proportions of kaolinite (0.6 to 3.4%) and chlorite, (1.9 to 6.8%; Table 4). Clay minerals, such as kaolinite and chlorite, provide potential attenuation sites for arsenic, boron, lithium, and/or sulfate due to the presence of surface hydroxyl groups (Goldberg 1997; Lins and Puls, 2002; Mohapatra et al. 2007; Sokolova and Alekseeva 2008; Li and Liu 2020). Chlorite is of particular importance for the attenuation of arsenic, as it is an iron-rich mineral which contains a hydroxide interlayer that provides adsorption sites (Lin and Puls, 2002). Kaolinite, a secondary clay mineral commonly formed during feldspar weathering, provides a particularly strong (i.e., irreversible) sorbing surface for lithium (Li and Liu 2020). Naturally occurring kaolinites tend to be enriched in lithium attenuated from groundwater (Anderson et al. 1989; Pogge von Strandmann et al. 2021; Steinhoefel et al., 2021).

4.3 Aqueous Geochemistry

UA groundwater from wells across the delineation network were analyzed for a range of geochemical parameters and data from October 2012 to November 2023 are presented in Figures 1 through 8. For clarity in interpretation, wells are arranged from east to west in the legends, with a warm (east) to cold (west) color scheme. Concentrations discussed in the following subsections are inclusive of the two most recent years of monitoring data (December 2021 to November 2023). The groundwater data used in the site evaluation are presented in Attachment H.

CCR porewater (i.e., CCR source water) from porewater wells (L4, LPZ-1, LPZ-3, and LPZ-17) distributed across the WAPS were collected April 2017 and analyzed for a range of geochemical parameters. The United States Environmental Protection Agency (USEPA) considers the use of porewater data as the most appropriate approach to estimate constituent fluxes to groundwater from CCR surface impoundments. As per USEPA, “this is because porewater better represents the leachate seeping from the bottom of the impoundment than impoundment water samples” (USEPA 2015). CCR porewater data are presented in Table 5 and discussed in the following subsections.

4.3.1 Exceedance Parameters

Arsenic concentrations in groundwater were consistently below the GWPS of 0.010 milligrams per liter (mg/L) in background wells and compliance wells, with two exceptions, 21R and 51. Arsenic concentrations in exceedance of the GWPS were identified[4] at compliance wells 21R (21R was installed to replace 21; 21 was decommissioned in 2019) and 51 (51 was installed to replace 24; 24 was decommissioned in 2019) (Figure 1). Wells 21R and 51 are located near the northwest corner of the WAPS. Arsenic at well 21R has been elevated post-closure, with concentrations ranging from 0.0210 to 0.0345 mg/L for the last two years of monitoring data (December 2021 to November 2023). Arsenic at well 51 has also been elevated post-closure, with concentrations ranging from 0.0182 to 0.0308 mg/L. The trends at well 51 are consistent with previous arsenic values measured in well 24 prior to decommissioning. Arsenic concentrations at wells 21R and 51 are also consistent with those of porewater wells, which had arsenic concentrations ranging from

[4] Using data pooled from both original and replacement wells collected from 2015 onward.

0.0123 to 0.0351 mg/L during the 2017 sampling event. Arsenic concentrations at other wells within the delineation network (including background wells) were low, with concentrations ranging from below detection to 0.0017 mg/L.[5]

Boron concentrations were generally stable or decreased through time across the site (Figure 2). In background wells 32 and 34, boron concentrations were consistently low (between 0.075 and 0.206 mg/L). Boron concentrations at wells 49, 50, and 51 are slightly elevated above background but below the GWPS of 2.0 mg/L during recent events. Exceedances above the GWPS were reported in compliance wells 21R, 22, 23, 35, and 27. Boron at wells 21R, 22, and 27 decreases over time, with values ranging from 0.13 to 4.84 mg/L. The exceedance at monitoring well 27 may be attributed to groundwater flow conditions prior to closure, wherein groundwater was mounded within the WAPS and flowed radially from the unit and migrated to the nearby wetland (Section 2 of the N&E Report). Concentrations at well 23 have an average value of 9.3 mg/L for the previous two years of data. Well 35 has exhibited an increase in boron since closure activities started in 2019, with a range of concentrations (9.58 to 18.1 mg/L) reported over the last two years. Localized post-closure flow conditions at well 35 are likely contributing to the increase in boron. However, once water levels in the WAPS reach equilibrium, concentrations of boron are expected to stabilize and decline in the future. Boron concentrations in porewater wells ranged from 21 to 28 mg/L in 2017. These concentrations suggest that the porewater may be contributing to the stable to increasing boron concentrations observed at wells 23 and 35.

Lithium concentrations remained stable or decreased over time in the wells across the delineation network (Figure 3). Concentrations at background wells 32 and 34 have been consistently low, ranging from 0.0029 to 0.0051 mg/L and 0.0032 to 0.0160 mg/L for wells 32 and 34, respectively. Lithium concentrations across the site have generally been below the GWPS of 0.040 mg/L but elevated relative to background wells, with two exceptions. Lithium exceeds the GWPS at well 22 but exhibits a decreasing trend over time, with concentrations ranging from 0.0419 to 0.0620 mg/L. There was a spike in lithium during the May 2023 sampling event at well 51, but this was not determined to represent an exceedance and all other data points for well 51 are below the lithium GWPS. Lithium concentrations at porewater wells were generally similar to or greater than that of well 22, with reported values ranging from 0.046 to 0.109 mg/L during the 2017 sampling event.

Sulfate concentrations across the site were stable or decreased over time, except in well 35 (Figure 4). In background wells 32 and 34, sulfate concentrations were consistently low (between 45 and 82 mg/L). Exceedances above the sulfate GWPS of 400 mg/L were reported at wells 23 and 35. Sulfate concentrations remained relatively stable in well 23, unlike the increasing boron concentration, ranging from 413 to 471 mg/L. In well 35, sulfate concentrations exhibited an increasing trend post-closure, similar to boron, with variable sulfate concentrations (476 to 1190

[5] The apparent spike in arsenic concentrations in most wells (except 21R and 51) during the May 2023 sampling event is a result of the higher detection limit (0.0087 mg/L) that was used during analysis on that date, rather than an increase in arsenic in the groundwater.

mg/L) over the last two years. Other compliance and monitoring wells had sulfate concentrations below the GWPS. Concentrations at these wells were similar to or slightly greater than that of background wells, ranging from 77 to 159 mg/L. Porewater wells exhibited a wide range of sulfate concentrations during the 2017 sampling event (370 to 1270 mg/L), which is generally consistent with the range of concentrations observed at wells 23 and 35.

TDS concentrations across the network were stable over time, with the exception of well 35 (Figure 5). In background wells 32 and 34, TDS concentrations ranged from 514 to 845 mg/L. TDS in well 35 exceeded the GWPS of 1,200 mg/L and has increased following closure activities in 2019. TDS trends in well 35 have a positive and linear correlation with sulfate trends (R^2 = 0.97, Figure 6), which indicates that sulfate may be a major contributor to elevated TDS at well 35. Other compliance and monitoring wells had TDS concentrations that were generally within the range of background measurements, though well 23 consistently had TDS concentrations above background but below the GWPS. TDS concentrations at the porewater wells ranged from 768 to 2090 mg/L, which is similar to the range observed at well 35 in the last two years (918 to 1940 mg/L).

4.3.2 Redox/pH Summary

The oxidation-reduction (redox) potential (ORP) and pH in aqueous systems are major controls on the speciation of redox-active chemicals. ORP and pH will affect arsenic and sulfate (COCs for WAPS groundwater) mobility in groundwater and determine the stability of iron and manganese oxyhydroxides.

In wells across the groundwater monitoring network, groundwater pH values have declined since placement of CCR and use of the WAPS ceased in the late 1990s (Figure 7). In recent years, pH values are circumneutral and fairly consistent across the site (ranging between 6.8 to 7.7 standard units [SU]), though compliance wells along the north side of the WAPS tend to have slightly higher pH values than background wells. This may reflect a consistent influence from the pond water, which had reported pH values ranging from 7.6 to 10 SU (Table 5).

Redox conditions vary across the site, with the east side of the WAPS generally exhibiting more oxidizing conditions and the west side exhibiting more reducing conditions (Figure 8). The oxidizing conditions are a result of these wells being located closer to a recharge zone where sand and/or gravel are near the land surface. The presence of a silty, organic-rich deposit on the west side of the WAPS may be creating the observed reducing conditions in that area (EPRI 2002). More reducing conditions exist at compliance wells 21R, 22D, 23, 27, and 51, background well 34, and leachate porewater wells. Reducing conditions at 21R and 51 are consistent with the elevated arsenic concentrations at these wells, which is likely attributed to the lower stability of iron and/or manganese oxyhydroxides and the desorption of arsenic associated with these phases and/or changes in arsenic speciation as discussed in Section 4.3.3.

4.3.3 Pourbaix Diagrams

Eh-pH, or Pourbaix, diagrams can be used to illustrate the predicted stability of specific phases at thermodynamic equilibrium under the conditions observed for a groundwater sample. Select crystalline mineral species were suppressed to be representative of groundwater conditions (e.g., mineral formation not anticipated to be kinetically favored), except when identified in XRD data from solids in the site (e.g., magnetite). Conditions observed at well 21R on 22 August 2023 were used to represent wells with arsenic exceedances, which tend to be more reducing (Table 6). Conditions observed at well 22 on 25 August 2023 were used to represent wells with more oxidizing conditions (Table 6).[6]

Using conditions observed at wells 22 and 21R in August 2023 (Table 6), magnetite is predicted to be stable in the aquifer (Figure 9a and Figure 9b) The predicted stability of magnetite is consistent with XRD analysis which detected magnetite in aquifer solids at abundances ranging between 0.2 and 0.5 wt% (Table 4). When magnetite is suppressed, amorphous iron oxyhydroxides (represented by ferrihydrite) are generally predicted to be stable in the aquifer at locations with oxidizing (Figure 9c) conditions. Iron oxides, whether crystalline or amorphous, may provide potential mineral surfaces for sorption of arsenic, boron, lithium, and/or sulfate within the aquifer. Ankerite, which is represented by siderite in Figures 10a – 10d, may be stable under reducing conditions (Figure 9d), which is consistent with XRD detection of ankerite in aquifer solids at abundances ranging from 1.3 to 6.0 wt%. In general, iron oxyhydroxide minerals appear to be less stable under the more reducing conditions observed in site groundwater and as such, select wells (21R, 23, 34, and 51) may experience dynamic equilibrium conditions in which dissolution and subsequent precipitation of these minerals are more likely occur.

Arsenic is predicted to primarily exist as the arsenic (V) species $HAsO_4^{2-}$ even under reducing aquifer conditions at well 21R (Figure 10), which is a more readily attenuated arsenic (V) species. Under oxidizing conditions, the presence of $HAsO_4^{2-}$ in combination with more stable ferrihydrite suggests the potential for arsenic attenuation via interaction of arsenic (V) species with iron oxides.

A review of Eh-pH conditions for manganese found that solid phase manganese minerals are not predicted to be stable under conditions that exist at the compliance and background wells (Figures 11a and 11b).

4.3.4 Total and Dissolved Iron and Manganese Concentrations

The distribution of iron and manganese between total and dissolved phases can provide insights on site redox conditions and constituent behavior. A comparison of the total and dissolved iron and manganese data for the Q2 and Q3 2023 sampling events is provided in Table 7. Total iron was detected at least once at all sample locations, with values ranging from 0.037 mg/L (well 22, Q2 2023) to 8.5 mg/L (well 21R, Q2 2023). Dissolved iron was detected at 6 of the 11 sample

[6] Field ORP measurements were converted to Eh by adding +200 millivolts to correct for the Ag/AgCl electrode.

locations, with values ranging from 0.14 mg/L (well 23, Q3 2023) to 6.8 mg/L (background well 34, Q3 2023). Reducing conditions exist at all six sampling locations that had detectable dissolved iron, indicating that reducing conditions are contributing to dissolved iron in the groundwater. Where dissolved iron was detected, the dissolved concentrations were typically a significant (>50%) portion of the total iron identified. These results align with the findings of the Pourbaix diagrams, which predicted lower ferrihydrite stability at wells with more reducing conditions (Figures 10c and 10d).

Total manganese was detected at all locations analyzed, with reported values ranging from 0.012 mg/L (well 22, Q3 2023) to 1.3 mg/L (background well 34, Q3 2023). Dissolved manganese was detected at 12 of the 13 locations, with values ranging from 0.0044 (well 49, Q3 2023) to 1.3 (background well 34, Q3 2023). Where dissolved manganese was detected, dissolved concentrations as a percent of total concentrations varied widely, from 0 to greater than 100%. This is consistent with the widespread mobilization of manganese to the aqueous phase predicted by the Pourbaix diagrams (Figures 11a and 11b) and the lack of observed crystalline manganese-bearing minerals (like rhodochrosite) across the site (Table 4).

4.3.5 Total and Dissolved Organic Carbon Concentrations

Concentrations of organic carbon in groundwater can provide insights into redox conditions and constituent mobility. A comparison of aqueous TOC and dissolved organic carbon (DOC) concentrations for the Q2 and Q3 2023 sampling events is provided in Table 8. TOC and DOC were detected at all sampling locations during this time period. TOC concentrations ranged from 0.83 mg/L (well 27, Q3 2023) to 8.9 mg/L (well 35, Q2 2023) and DOC ranged from 0.88 mg/L (background well 32, Q3 2023) to 26 mg/L (well 22D, Q3 2023). The silty, organic-rich deposit on the west side of the WAPS likely contributes to higher TOC and DOC concentrations, particularly at well 34 which had higher TOC and DOC concentrations than most wells for both the 2023 Q2 and Q3 sampling events. In most cases, DOC concentrations were greater than or equal to TOC, suggesting that much of the organic carbon in the aquifer is dissolved. The presence of organic carbon can contribute to reducing conditions, which impacts the speciation and mobility of arsenic, iron, and manganese and the reduction of sulfate. Further, DOC can influence arsenic mobility by competing for binding sites on iron oxides, passivating the surface of iron oxides to reduce their reactivity, or serving as a substrate for iron-reducing microbial species, all of which could increase arsenic mobility via reduced attenuation with iron mineral surfaces (Aftabtalab et al. 2022). Wells with arsenic exceedances (51 and 21R) had TOC and DOC concentrations ranging from 1.5 to 3.3 mg/L and 1.6 to 2.6 mg/L (TOC and DOC, respectively), which are similar to that of other wells in the network.

4.3.6 Major Ion Distribution and Groundwater Signatures

A piper diagram was constructed using data from the delineation network and leachate to visualize major ion distributions in UA groundwater. Piper diagrams are a common tool for assessing geochemical similarities or differences between aqueous samples. The major ion distribution is

similar for most wells in the delineation network (Figure 12) and is characterized by relatively high contributions of calcium and bicarbonate ions. The relatively high contribution of carbonate species to groundwater composition is consistent with the abundance of carbonate-bearing minerals such as calcite and dolomite in the site solids (Table 4). Wells 23 and 35, which have boron and sulfate exceedances, exhibit a different ion distribution, with higher abundances of sulfate and lower abundances of bicarbonate relative to other wells in the network. The major groundwater composition in wells 23 and 35 is similar to that of the source water samples, which suggests that porewater may have contributed to boron and sulfate exceedances at these wells.

5. LABORATORY ATTENUATION TESTING

The aquifer solids described in Section 4.2 were submitted to SIREM laboratory to test attenuation behavior of arsenic using batch testing. Batch test studies combine soil and groundwater collected from the site to evaluate the sorption and desorption of chemical constituents. The methods and results of batch adsorption testing completed to evaluate attenuation of the arsenic with Site solids is described below. Batch desorption testing was not completed due to the redox sensitivity of arsenic, which contributed to poor recoveries in the batch attenuation testing.

5.1 Batch Attenuation Testing Methods

Aquifer solids from boring SB-34 and groundwater from well 51 were used for the batch attenuation tests. Test bottles (referred to as a microcosm) were constructed with five soil to water ratios (Table 9). The groundwater added to the microcosms was spiked with sodium arsenite to a target concentration of 0.1 mg/L arsenic, and the sample bottles were allowed to tumble for seven days. An initial sample of the stock solution was collected on Day 0 and a control sample (i.e., MW-51 groundwater with no aquifer solids) was collected on Day 7 following tumbling to evaluate any less to interactions with the bottleware or ambient conditions. Duplicates were constructed for each microcosm, including the control sample.

After seven days of contact time, an aliquot of the free liquid was collected and filtered through a 0.45-micron filter prior to analysis for dissolved arsenic. Analysis of the dissolved phase is important to adequately measure the partitioning of mass between the solid and liquid fractions of the experiment. The redox and pH were measured for each batch test at the beginning and end of the contact period and in the control samples.

5.2 Batch Attenuation Testing Results

While pH between the initial and final control samples remained consistent, ORP increased from -136 mV to -58 mV, suggesting a slight oxidation of the sample bottles during the experimental period. pH and redox results were generally consistent between the control and test samples, except for the 1:1 soil:water ratio microcosms which had a significantly lower ORP recorded (Table 9). The cause of the anomalously low ORP values for this soil:water ratio is not immediately apparent. The recovery of arsenic in the control samples was approximately 58% of the initial total, with the loss of aqueous arsenic likely associated with the observed change in redox conditions in the control.

While interpretation of the data is limited by the poor recovery in the control samples, the data obtained from the tests (Table 9) were used to construct 5-point isotherms for arsenic by averaging duplicate results for each soil:solution ratio. Mathematical fitting was used to calculate the attenuation distribution coefficients (K_d), assuming linear adsorption. The linear adsorption equation was used:

$$q_e = K_d \times C_e \quad \text{Eq. 1}$$

where q_e is the mass of constituent adsorbed to the solid phase at equilibrium, C_e is the remaining aqueous constituent concentration at equilibrium, and K_d is the linear sorption coefficient (reported in liters per kilogram [L/kg]). The linear data output is provided as Figure 13.

The data were also fitted to a non-linear Langmuir isotherm:

$$q_e = \frac{q_m K_L C_e}{1 + K_L C_e} \quad \text{Eq. 2}$$

where q_m is the inverse of the slope and K_L is the Langmuir distribution coefficient. The adsorption data were linearized according to:

$$\frac{C_e}{q_e} = \frac{1}{(K_L \times q_m)} + \frac{C_e}{q_m} \quad \text{Eq. 3}$$

A common non-linear Freundlich equation was also used:

$$q_e = K_F (C_e)^{1/n} \quad \text{Eq. 4}$$

where q_e is the mass of constituent adsorbed to the solid phase at equilibrium, C_e is the remaining aqueous constituent concentration at equilibrium, K_F is the Freundlich distribution coefficient, and $1/n$ is a non-linearity constant. The adsorption data were plotted as log-transformed values to perform the non-linear isotherm fitting using the linearized Freundlich equation:

$$log(q_e) = \log(K_F) + (1/n)\log(C_e) \quad \text{Eq. 5}$$

The calculated linear, Langmuir, and Freundlich distribution coefficients (K_d, K_L, and K_F, respectively) and $1/n$ values are shown in Table 10.

The linear K_d of 36.4 L/kg was selected for well 51 based on its goodness-of-fit ($R^2 = 0.69$) and compatibility with values reported in literature (which range from several orders of magnitude from 1 to $1x10^5$; USEPA 2005). As noted above, the calculated K_d may be influenced by the loss of arsenic in the control solution; the batch attenuation results instead may serve as a proof of concept for the attenuation of arsenic in the system in lieu of a more quantitative measurement.

6. GEOCHEMICAL CONCEPTUAL SITE MODEL

6.1 Source and Mobilization Mechanisms

Arsenic, boron, sulfate, and lithium are naturally present in coal deposits and are concentrated within CCR. Sulfate may also be present in CCR as a byproduct of flue gas desulphurization. Arsenic, boron, and lithium were detected within UA aquifer solids from compliance and background wells, although groundwater concentrations of these constituents in background wells consistently do not exceed GWPSs. Arsenic, boron, sulfate, and lithium all exhibited elevated concentration in CCR porewater at the time of collection (2017). While naturally occurring sources of arsenic, boron, and lithium are present in the UA as supported by solid phase characterization of background material, the primary source of these constituents, as well as sulfate, in the UA is expected to be the WAPS CCR porewater. The elevated concentrations of sulfate are a major contributor to the exceedance of TDS identified at well 35.

6.2 Potential Attenuation Mechanisms

Arsenic is predicted to exist primarily as the arsenic (V) species $HAsO_4^{2-}$ which has a high affinity for metal (hydr)oxides. Neutral arsenic (III) species $As(OH)_3$ may also be present in the UA, particularly under reducing conditions. Boron is anticipated to largely be present as the neutral H_3BO_3 species, as groundwater pH values are below the pK_a for boric acid (9.2 SU). The presence of iron oxides in aquifer solids (Table 4) suggests that a portion of the arsenic, boron, lithium, and/or sulfate in the groundwater could be attenuated via surface (inner- and outer-sphere) complexation reactions. Aluminum and manganese oxyhydroxides, clay minerals, and calcite (Table 4) in the aquifer solids may also serve as sorption sites for arsenic, boron, lithium, and/or sulfate (Goldberg 1997, Sokolova and Alekseeva 2008, Robinson et al. 2018, Rahman et al. 2019, Nguyen et al. 2021, Elbana and Osman 2023). This suggests that attenuation of these constituents via sorption mechanisms is possible, though it will be dependent on speciation, redox conditions, and pH in the UA. In addition, bioremediation of sulfate (via microbial sulfate reduction) may naturally occur in the UA under reducing conditions. Attenuation of sulfate will likely contribute to a reduction of TDS in the groundwater.

TABLES

Table 1 - Total Organic Carbon, Loss on Ignition, Sulfate, and Sulfide in Aquifer Solids *Geosyntec Consultants, Inc.*
Geochemical Conceptual Site Model
Hennepin West Ash Pond System, Illinois

Field Boring Location	SB-22		SB-34	SB-51
Sample Depth (ft bgs)	26-27	29-30	32-33	42-43
Location	Downgradient		Background	Downgradient
Sample Collection Date	4-Mar-21	4-Mar-21	4-Mar-21	4-Mar-21
Field Boring Description	Fine sand	Gravel with sand and trace clay	Fine-medium sand	Silty clay with trace sand
TOC %	0.34	4.6	1.9	3.6
LOI %	11.6	15.3	13.3	21.5
Sulfate (%)	< 0.1	< 0.1	< 0.1	< 0.1
Sulfide (%)	< 0.04	0.06	0.09	0.18

Notes
Sample depth is shown in feet below ground surface (ft bgs)
TOC - total organic carbon
LOI - loss on ignition
Non-detects are shown as less than the reporting limit.

Table 2 - Bulk Characterization of Aquifer Solids
Geochemical Conceptual Site Model
Hennepin West Ash Pond System, Illinois

Field Boring Location	SB-22		SB-34	SB-51
Sample Depth (ft bgs)	26-27	29-30	32-33	42-43
Location	Downgradient		Background	Downgradient
Sample Collection Date	4-Mar-21	4-Mar-21	4-Mar-21	4-Mar-21
Field Boring Description	Fine sand	Gravel with sand and trace clay	Fine-medium sand	Silty clay with trace sand
Aluminum	2800	3700	5000	8200
Antimony	< 0.8	< 0.8	< 0.8	< 0.8
Arsenic	5.1	8.4	2.7	3.5
Barium	20	31	47	84
Beryllium	0.20	0.87	0.29	0.50
Bismuth	0.13	0.26	0.23	0.59
Boron	6	7	5	10
Cadmium	0.76	2.9	0.53	0.89
Calcium	56000	36000	52000	91000
Chromium	79	130	45	27
Cobalt	5.2	9.8	6.9	9.3
Copper	11	25	8	14
Iron	9400	12000	10000	14000
Lead	7.7	28	6.1	11
Lithium	4	6	6	12
Magnesium	21000	16000	13000	15000
Manganese	310	220	260	350
Molybdenum	3.1	5.0	0.9	2.0
Nickel	15	43	12	19
Potassium	910	1200	1200	1900
Phosphorous	350	330	380	430
Selenium	< 0.7	0.8	< 0.7	1.1
Silicon	5400	1600	7200	4500
Silver	< 0.05	0.08	< 0.05	0.06
Sodium	190	160	180	170
Thallium	0.13	0.26	0.16	0.25
Tin	< 0.5	0.5	1.1	0.6
Tungsten	0.07	0.10	0.06	0.05
Uranium	1.3	1.8	0.65	1.2
Vanadium	17	41	12	18
Yttrium	6.1	7.6	5.7	8.0
Zinc	46	91	40	67

Notes
Sample depth is shown in feet below ground surface (ft bgs)
All results are shown in µg/g (microgram per gram).
Total metals samples prepared via method SW 3050 and analyzed via USEPA method 6020A.
Non-detect results are shown as less than the reporting limit.

Notes:
mg/L - milligrams per liter
mV - millivoltes
SU - standard units

Table 10 - Arsenic Partition Coefficients
Geochemical Conceptual Site Model
Hennepin West Ash Pond System, Illinois

Groundwater Sample ID	Geologic Material Sample ID	Analyte	Isotherm	Variable	Value
MW-51	**SB-34 23-33'**	**Arsenic**	Linear	R^2	0.69
				K_d (L/kg)	**36.40**
			Langmuir	R^2	0.90
				q_m (mg/g)	0.004
				K_L (L/kg)	**2.43E+08**
			Freundlich	R^2	0.60
				1/n	0.15
				K_F (L/kg)	**109.5**

Notes

K_d - linear partition coefficient

K_L - Langmuir partition coefficient

K_F - Freundlich partition coefficient

q_m - inverse of the slope of the linearized Langmuir isotherm

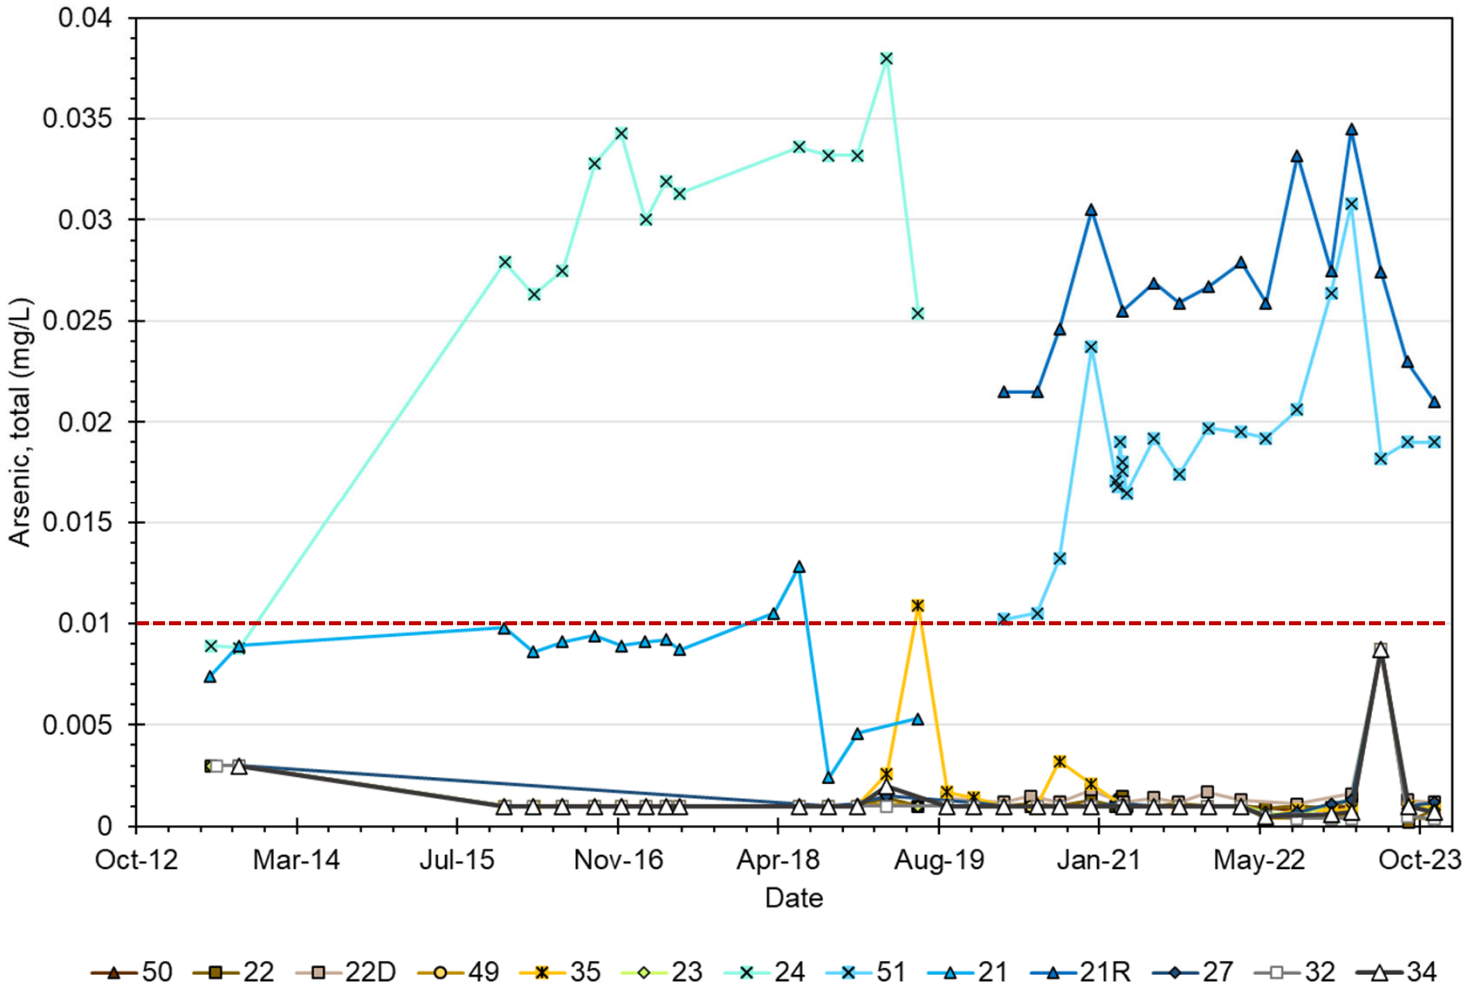
n - non-linearity constant of the Freundlich isotherm

ft bgs - feet below ground surface

L/kg - liters per kilogram

mg/g - milligrams of arsenic per gram of soil

FIGURES



Notes:
1. Wells 21 and 24 were abandoned during closure activities and replaced with 21R and 51, respectively.
2. mg/L: milligrams per liter
3. Red dashed line denotes groundwater protection standard.

Notes:
All elevation data are presented relative to the North American Vertical Datum 1988 (NAVD88), GEOID 12A
Type refers to the role of the well in the monitoring network: background (B), compliance (C), or water level measurements only (WLO)
WLO wells are temporary pending implementation of impoundment closure per an approved Construction Permit application
BGS = below ground surface
ft = foot or feet
HSU = Hydrostratigraphic Unit
PVC = polyvinyl chloride
UA = uppermost aquifer

DRILLING METHOD Hollow Auger
DATE DRILLED 12/9/82
DRILLED BY Roberts
LOGGED BY Maxeiner
PIEZOMETER Yes

GROUNDWATER LEVELS
Encountered at 8.0 Feet
___ Hours after completion ___ Feet
6 Days after completion 8.0 Feet
___ after completion ___ Feet

NOTE: Refer to the attached GENERAL NOTES and NOTATION USED ON RECORDS OF SUBSURFACE EXPLORATION for abbreviations, explanations, and qualifications relative to this log.

Monitoring Well No. 34

PROJECT Title: Hennepin West Ash Impoundment
DRILL RIG: Hollow Stem Auger
DRILLER: Boart Longyear

DATE: 8-22-96
HOLE DIA.: 7 in.
FINAL GW: 7.54 ft.

LOGGED BY: Mueller/Tu
SAMPLER: Split Spoon
HOLE ELEV.: 448.19 ft. MSL

DESCRIPTION	USCS CLASS	GRAPHIC LOG	DEPTH	SAMPLE
Silty clay, trace of plant debris, little fine-grained sand, very dark brown in color, medium to high plasticity (alluvium).			0	C-1A
			5	C-1B
			10	C-1C
			15	C-1D
			20

Monitoring Well No. 34

PROJECT TITLE: Hennepin West Ash Impoundment
DRILL RIG: Hollow Stem Auger
DRILLER: Boart Longyear

DATE: 8-22-96
HOLE DIA.: 7 in.
FINAL GW: 7.54 ft.

LOGGED BY: Mueller/Tu
SAMPLER: Split Spoon
HOLE ELEV.: 448.19 ft. MSL

DESCRIPTION	USCS CLASS	GRAPHIC LOG	DEPTH	SAMPLE	WELL CONSTRUCTION DETAIL
Clayey silt, trace to little fine-grained sand and shell fragments, soft, olive-gray. Wet.			20–26	C-1E, C-1F	Bentonite Seal; 2 in. 40 Schedule PVC
Sand, fine-grained to medium-grained, well-sorted, quartz, trace of silt, loose. Yellowish brown color grades to olive gray below 31 ft.			27–38	C-1G	#7 Fine Sand; #5 Fine Sand; 0.01 Slotted Well Screen; Holeplug

X-Ray Diffraction Analytical Data

Quantitative X-Ray Diffraction by Rietveld Refinement

Report Prepared for:	*Environmental Services*
Project Number/ LIMS No.	*Custom XRD/MI4516-MAR21*
Sample Receipt:	*March 12, 2021*
Sample Analysis:	*March 25, 2021*
Reporting Date:	*April 8, 2021*

Instrument:	BRUKER AXS D8 Advance Diffractometer
Test Conditions:	Co radiation, 35 kV, 40 mA Regular Scanning: Step: 0.02°, Step time: 1s, 2θ range: 3-80°
Interpretations :	PDF2/PDF4 powder diffraction databases issued by the International Center for Diffraction Data (ICDD). DiffracPlus Eva and Topas software.
Detection Limit :	0.5-2%. Strongly dependent on crystallinity.

Contents:

1) Method Summary
2) Quantitative XRD Results
3) XRD Pattern(s)

ACCREDITATION: SGS Minerals Services Lakefield is accredited to the requirements of ISO/IEC 17025 for specific tests as listed on our scope of accreditation, including geochemical, mineralogical and trade mineral tests. To view a list of the accredited methods, please visit the following website and search SGS Canada - Minerals Services - Lakefield: http://palcan.scc.ca/SpecsSearch/GLSearchForm.do.

Method Summary

The Rietveld Method of Mineral Identification by XRD (ME-LR-MIN-MET-MN-D05) method used by SGS Minerals Services is accredited to the requirements of ISO/IEC 17025.

Mineral Identification and Interpretation:

Mineral identification and interpretation involves matching the diffraction pattern of an unknown material to patterns of single-phase reference materials. The reference patterns are compiled by the Joint Committee on Powder Diffraction Standards - International Center for Diffraction Data (JCPDS-ICDD) database and released on software as Powder Diffraction Files (PDF).

Interpretations do not reflect the presence of non-crystalline and/or amorphous compounds, except when internal standards have been added by request. Mineral proportions may be strongly influenced by crystallinity, crystal structure and preferred orientations. Mineral or compound identification and quantitative analysis results should be accompanied by supporting chemical assay data or other additional tests.

Quantitative Rietveld Analysis:

Quantitative Rietveld Analysis is performed by using Topas 4.2 (Bruker AXS), a graphics based profile analysis program built around a non-linear least squares fitting system, to determine the amount of different phases present in a multicomponent sample. Whole pattern analyses are predicated by the fact that the X-ray diffraction pattern is a total sum of both instrumental and specimen factors. Unlike other peak intensity-based methods, the Rietveld method uses a least squares approach to refine a theoretical line profile until it matches the obtained experimental patterns.

Rietveld refinement is completed with a set of minerals specifically identified for the sample. Zero values indicate that the mineral was included in the refinement calculations, but the calculated concentration was less than 0.05wt%. Minerals not identified by the analyst are not included in refinement calculations for specific samples and are indicated with a dash.

DISCLAIMER: This document is issued by the Company under its General Conditions of Service accessible at http://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein. Any holder of this document is advised that information contained hereon reflects the Company's findings at the time of its intervention only and within the limits of Client's instructions, if any. Actinolite	-	-	0.8	-
TOTAL	100	100	100	100

Zero values indicate that the mineral was included in the refinement, but the calculated concentration is below a measurable value.

Dashes indicate that the mineral was not identified by the analyst and not included in the refinement calculation for the sample.

The weight percent quantities indicated have been normalized to a sum of 100%. The quantity of amorphous material has not been determined.

1. INTRODUCTION

35 Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845.650(d)(1) requires the owner or operator of a coal combustion residuals (CCR) surface impoundment (SI) to characterize the nature and extent of a release and relevant site conditions that may affect the remedy ultimately selected for a CCR SI if any constituent regulated under 35 I.A.C. § 845 is found to exceed[1] the groundwater protection standard (GWPS). A report documenting the nature and extent of constituents detected above the GWPS that are attributable to the Hennepin Power Plant (HPP) West Ash Pond System (WAPS) was prepared and submitted to the Illinois Environmental Protection Agency (IEPA) dated May 9, 2024 [1].

Following submittal, additional investigation was completed in October and November 2024 to further characterize the bedrock confining unit and support a permit-level design of a deep cutoff wall as a groundwater corrective action at the WAPS. The additional investigation included the following:

- Advancement of three borings into competent bedrock along the perimeter of the WAPS, including coring of the bedrock
- Continuous logging of the materials including Rock Quality Designation (RQD) of the bedrock
- Collection of aquifer material from the boring nearest to monitoring well 21R for geochemical evaluation
- Packer testing within the bedrock to evaluate ranges in hydraulic conductivity

Documentation of site investigation activities described above is included as **Appendix A.** This report supplements the existing Nature and Extent Report with the results from the additional investigation and initial groundwater monitoring completed in 2024.

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of Dynegy Midwest Generation, LLC's operating permit application for the HPP WAPS. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, Dynegy Midwest Generation, LLC has not identified any actual exceedances.

2. ADDITIONAL INVESTIGATION RESULTS

2.1 Geology

As previously described in the Nature and Extent Report [1] materials at the site have been categorized into two hydrostratigraphic units at the WAPS based on stratigraphic relationships, geologic composition, and common hydrogeologic properties. The units, listed from surface downward, are summarized as follows:

- **Uppermost Aquifer (UA)**: Includes the Cahokia Alluvium which consists of fine-grained river deposits comprised of silts and clays (upper UA), fine-medium sands (middle UA), and highly permeable glacial outwash sands and gravels of the Henry Formation (lower UA). The UA contains variable amounts of cobbles and boulders within a sand and gravel matrix. Both the prevalence and size of the cobbles and boulders increase with depth.

- **Bedrock Confining Unit**: Comprised of interbedded layers of shales with thin limestone, sandstone, and coal beds. Borings along the perimeter of the nearby East Ash Pond System confirm the presence of shale bedrock between elevations ranging from 399.2 to 410.2 feet[2] (ft) [2].

The additional borings installed to further characterize the bedrock confining unit (B100, B101, and B102) indicate consistent geologic materials and stratigraphic relationships (**Appendix A**). Additional details on the hydrostratigraphic units encountered by the borings are summarized as follows:

- **Uppermost Aquifer (UA)**: Consistent with previous borings the UA was encountered at thicknesses up to 85 ft and consisted of sand, gravel, and cobbles south and east of the WAPS (B101 and B102), while materials west of the WAPS (B100) were primarily silty clay with intermittent layers of sand, gravel, and cobbles.

- **Bedrock Confining Unit:** Weathered shale and shaley limestone was observed at depths of 70 to 85 ft, with a thickness of approximately 10 to 20 ft. The weathered bedrock was underlain by competent shale with intermittent beds of shaley limestone. RQD measurements within the bedrock range from 32 percent (%) to 72% with higher measurements generally occurring at greater depths. The elevation of the weathered bedrock ranged from approximately 374 ft in B101 to 385 ft in B102 while competent bedrock was encountered at an elevation between 364 and 365 ft in all three borings.

2.2 Hydraulic Conductivities

Hydraulic conductivity was evaluated in the borings using packer tests as described in **Attachment A**. Results indicate that hydraulic conductivities in the shale bedrock range from 2.2×10^{-6} centimeters per second (cm/s) to 1.1×10^{-5} cm/s, with a geometric mean of 3.4×10^{-6} cm/s. This is significantly lower than measurements in the UA which ranged from 1.2×10^{-2} cm/s in the Henry Formation (deep UA) to 1.3×10^{-4} cm/s in the Cahokia Alluvium silt (shallowest UA). The geometric mean hydraulic conductivity for the sand and gravel portion of the UA is 6×10^{-3} cm/s and 1.7×10^{-2} cm/s for wells finished in the glacial outwash gravels of the Henry Formation [3].

[2] All elevations in this report are referenced to North American Vertical Datum of 1988 unless otherwise noted.

2.3 Hydrogeologic Conceptual Site Model

The overall groundwater flow regime within the unlithified materials is consistent with topographically-controlled flow patterns, where infiltration of precipitation recharges groundwater and flows north and west near the site towards the Illinois River. Flow patterns within the site hydrostratigraphic units are typically horizontal, with components of converging vertical (upward) flow near and underneath the river. Under typical post-closure conditions, groundwater flow directions at the WAPS are north, towards the river. During the operation of the impoundments, high local recharge to groundwater from sluicing of CCR created radial flow conditions near the impoundment; while groundwater flow was still predominantly towards the river, some of the groundwater beneath the impoundment flowed towards the adjacent wetlands located south and west of the WAPS.

Conceptually, source water from the WAPS, if present, migrates downward into the materials of the UA, either sand or silt/clay, and mixes with groundwater. Groundwater continues to migrate vertically in the low permeability silt/clay materials until it encounters the sand and gravel portions of the UA. In the sand and gravel, groundwater migrates horizontally to the north towards the Illinois River. Downward migration of groundwater within the UA is limited by the low permeability shale bedrock underlying the WAPS.

3. GEOCHEMICAL CONCEPTUAL SITE MODEL FOR ARSENIC (NATURE)

A geochemical conceptual site model (GCSM) was developed to describe the conditions of the groundwater in the vicinity of the HPP WAPS and is summarized here (full analysis originally presented in Appendix B of the Nature and Extent Report [1] to which this addendum is attached). The GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. Additional investigation was conducted to describe arsenic geochemistry in the groundwater west of the WAPS. The effects of the additional data collection on the arsenic GCSM are summarized here and described in detail in **Appendix B**.

Two soil samples were collected from boring B100, located in the vicinity of the wells with arsenic exceedances (21R and 51), at depths in the UA near the well screen intervals. The soil samples were analyzed for total organic carbon (TOC), loss on ignition (LOI), total metals, seven-step sequential extraction procedure (SEP), and X-ray diffraction (XRD). TOC and LOI had lower concentrations in the B100 samples than previous samples and there was high variability between the two samples. These results suggest that the organic matter required to drive reducing conditions in the groundwater is heterogeneous in the UA. Arsenic, iron, and manganese has similar concentrations relative to previous samples. Additionally, SEP results indicated that over 25% of soil associated arsenic was present in the metal oxide phases which sorb arsenic. XRD results were largely consistent with previous analyses.

Aqueous samples from background well 34 and compliance wells 21R and 51 were analyzed for arsenic speciation as well as total and dissolved metals. Arsenic in groundwater primarily exists as two species, depending on pH and redox conditions: reduced arsenic (III) forms the neutral complex $As(OH)_3$ and is more mobile, whereas oxidized arsenic (V) forms the oxyanion $HAsO_4^{2-}$ at neutral pH and is less mobile. At background well 34, arsenic (V) and arsenic (III) were present in the groundwater at approximately equal abundance. At wells 21R and 51, the mobile species arsenic (III) made up the majority (>85%) of the arsenic in the groundwater.

Although exceedances of typical CCR indicator parameters (*i.e.*, boron and sulfate) are observed elsewhere in the WAPS monitoring network, concentrations of both boron and sulfate have been decreasing at wells 21R and 51 since unit closure in 2020 (see Appendix B of the Nature and Extent Report [1] to which this addendum is attached). This suggests that there may have been previous influence of porewater on the UA soils at 21R and 51. Therefore, both the CCR porewater and native geological material are potential sources to the arsenic observed in the UA soils west of the WAPS.

Based on the historical data (described in the Nature and Extent Report [1] to which this document is attached) and the results of this additional investigation, the GCSM concludes that the arsenic exceedances observed at wells 21R and 51 at the western end of the WAPS are due to reducing conditions driving mobilization of arsenic from the soils (derived from either native materials or previous CCR porewater influence). The mobilization of arsenic is likely driven by reduction of less mobile arsenic (V) to arsenic (III). The primary mechanism of arsenic attenuation in the subsurface is sorption to iron oxides and oxyhydroxides under conditions where arsenic (V) is stable.

4. COMBINED GEOCHEMICAL AND HYDROGEOLOGIC CONCEPTUAL SITE MODEL FOR ARSENIC

4.1 Arsenic Conceptual Site Model

The conceptual site model (CSM) describing current conditions at the WAPS combining the hydrogeologic and geochemical CSMs for arsenic is as follows. Water that may come into contact with CCR in the WAPS becomes porewater within the unlined CCR unit. During operations, sluicing of CCR with elevated heads in the unit resulted in radial flow, likely causing porewater, potentially impacted with arsenic, to migrate downward into the UA. Previous influence of porewater on aquifer material west of the unit may have resulted in arsenic attenuation in the solid phase, likely on iron oxides/hydroxides. The arsenic exceedances observed at wells 21R and 51 (which are at the western end of the WAPS in the area with more reducing groundwater) are due to reducing conditions driving mobilization of arsenic from the soils (derived from either native materials or previous CCR porewater influence). In addition to physical attenuation mechanisms of dilution and dispersion, elevated arsenic concentrations may be attenuated via surface complexation reactions with metal (*i.e.,* aluminum, iron, and manganese) oxyhydroxides under more oxidizing conditions.

5. CONCLUSIONS AND FUTURE ACTIVITIES

In accordance with 35 I.A.C. § 845.650(d)(1), the nature and extent of GWPS exceedances of arsenic, boron, lithium, sulfate, and total dissolved solids have been described in sufficient detail in the Nature and Extent Report [1] and this Addendum to support a complete and accurate assessment of the corrective measures necessary to effectively clean up all releases from the WAPS.

Following closure, groundwater monitoring results are generally consistent with the conclusions in the Closure Plan [4] and site conditions are improving as follows:

- Water levels within the CCR are declining. Porewater monitoring wells have gone dry, indicating the level in the unit has declined.
- Trends for boron and sulfate, which are conservative indicators of CCR impacts, indicate concentrations are declining in all wells except wells 23 and 35. Concentrations at these two locations are potentially related to localized flow conditions that originated as a result of closure, but are expected to dissipate as the unit reaches equilibrium (predicted to occur in 2027).

These observations are consistent with the conceptual site models and constituent extents previously provided. Additional evaluation of arsenic concentrations (**Appendix B**) indicates that arsenic concentrations observed at wells 21R and 51 at the western end of the WAPS are due to mobilization of arsenic from the aquifer soils (derived from native material and/or previous CCR porewater influence) due to reducing conditions and not ongoing influence from unit porewater.

INTRODUCTION

This Technical Memorandum (Tech Memo) was prepared by Ramboll Americas Engineering Solutions, Inc. (Ramboll) for Luminant to document and summarize the bedrock investigation work performed, including soil boring advancement and packer testing to evaluate the permeability of the bedrock, at Hennepin Power Plant (HPP) West Ash Pond System (WAPS) between October and November 2024.

OBJECTIVES

The objectives of the field event were, for the WAPS specifically, to evaluate the: (1) ranges in depth to bedrock; (2) the type of bedrock; (3) variations in the bedrock weathering profile; and (4) bedrock properties to support the permit-level design of a deep cutoff wall as a groundwater corrective action at the WAPS.

These objectives were met through the following investigatory field tasks: (1) clearing utilities for each boring locations; (2) advancing three borings along the perimeter of the HPP WAPS through unconsolidated materials and into competent bedrock; (3) photographing observed materials observed; (4) characterizing the materials observed through continuous logging, including Rock Quality Designation (RQD) of the bedrock; (5) collecting and storing bedrock core materials onsite, (6) conducting packer testing on select intervals from each boring to evaluate ranges in bedrock hydraulic conductivities; and (7) abandonment of each borehole in accordance with I.A.C. 77 § 920.120.

SITE WORK ACTIVITIES

On-site work activities were conducted between October 28 and November 7, 2024. Boring installation and packer testing were performed by Cascade Drilling, LP (Cascade) with oversight and direction from Ramboll.

The following sections discuss site work methods and documentation of completed work.

UTILITY CLEARANCE

Prior to drilling, the proposed locations for borings B100, B101, and B102 shown on **Figure 1** were evaluated for the presence of underground utilities by Ground Penetrating Radar Systems (GPRS). GPRS utilized a ground penetrating radar antenna to scan a 10-foot

radius around the proposed well locations. No underground utilities were identified around the borings.

BORING INSTALLATION SUMMARY

Cascade used a Boart Longyear LS450 Sonic track mounted drill rig to advance three borings (B100, B101, and B102) through unconsolidated materials and into bedrock. Sonic tooling was utilized for the unconsolidated material (6-inch diameter core barrel), and an HQ coring system was utilized for bedrock material (4 7/8-inch diameter core barrel). The unconsolidated material was logged continuously by a Ramboll representative using the Unified Soil Classification System (USCS), and competent bedrock was logged continuously and characterized using the RQD method specified in the Designation D 6032-02, Standard Test Method for Determining Rock Quality Designation (ASTM, 2002). Bedrock cores were placed in core boxes labeled with the location ID, depth interval, and RQD, and were stored in the warehouse immediately east of the main power plant building. The boring logs are provided in **Attachment A** and described below.

Boring location B100, located in the northwest corner of the WAPS, contained 70 feet (ft) of unconsolidated material, consisting primarily of silty clay with intermittent layers of sand, gravel, and cobbles. The bedrock encountered between 70 and 85 ft below ground surface (bgs) was very weak, moderately fractured, moderately to highly weathered shale with inclusions of residual soil. The bedrock between 85 ft and 100 ft bgs was competent bedrock, slightly weathered, moderately fractured shale containing extremely narrow apertures, with intermittent bands of shaley limestone around 90 ft bgs. RQD decreased with depth, from 72% between 85 and 90 ft bgs, to 32% between 95 and 100 ft bgs. B100 was terminated at a depth of 100 ft bgs after encountering approximately 15 ft of competent bedrock.

Boring location B101, located in the northeast corner of the WAPS, contained 85 ft of unconsolidated material, consisting primarily of sand, gravel, and cobbles. The bedrock encountered between 85 and 95 ft bgs was competent bedrock, very strong, fine grained, moderately to intensely fractured shaley limestone with narrow to very narrow apertures. The bedrock between 95 and 105 ft bgs was competent bedrock, slightly to moderately weathered, intensely fractured shale containing very narrow apertures. In general, RQD's were considered poor, however RQD increased with depth. Within the shaley limestone from 85 to 95 ft bgs the RQD was 32%, and within the shale from 95 to 105 ft the RQD's increased from 39% to 52%. B101 was terminated at a depth of 105 ft bgs after encountering approximately 20 ft of competent bedrock.

Boring location B102, located south of the WAPS, contained 70 ft of unconsolidated material, consisting primarily of sand, gravel, and cobbles. The bedrock encountered between 70 and 90 ft bgs was very weak, extremely weathered shale that had transitioned into a residual soil. The bedrock between 90 and 95 ft bgs was competent bedrock, very strong, intensely fractured shale with very narrow apertures. The bedrock between 95 and 105 ft was competent bedrock, primarily fresh, very strong, slightly fractured to unfractured shaley limestone and shale. RQD's in the competent bedrock increased with depth. Within the shale from 90 to 95 ft bgs the RQD was 29%, and within the shaley limestone and deeper shale from 95 to 105 ft bgs the RQD's increased from 48% to 70%. B102 was terminated at a depth of 105 ft bgs after encountering approximately 15 ft of competent bedrock.

PACKER TESTING

The objective of packer testing was to evaluate the permeability of the bedrock at various depths and compositions to support permit-level design of a deep cutoff wall. Intervals selected for packer testing at each borehole were determined based upon field observations of fracture density and bedrock competency (RQD). The intervals selected and packer test specifications are summarized in **Table A**. The maximum injection pressure (P_{max}) was determined prior to each test to ensure the pressures in the test zone do not

exceed the confinement stress of the bedrock formation at depth. The P_{max} for each boring location interval was selected such that the estimated hydraulic conductivity would be measurable below 1 x 10^{-5} centimeters per second (cm/sec), without hydro-jacking the formation. The packer inflation pressures were calculated prior to testing, using the packer manufacturers specifications outlined in the technical manual (TAM International, 1999). Each borehole interval received a constant head injection test (Lugeon Test), consisting of five stages, with a predetermined water pressure associated with each stage: 1st stage (0.5 x P_{max}), 2nd stage (0.75 x P_{max}), 3rd stage (P_{max}), 4th stage (0.75 x P_{max}), and 5th stage (0.5 x P_{max}).

Table A. Packer Testing Specifications

Borehole ID	Packer Interval (ft bgs)	Test Length (ft)	RQD	P_{max} (pounds per square inch [psi])
B100	86.0 – 90.8	4.8	72%	60
	90.0 – 94.8	4.8	52%	62
	95.0 – 99.8	4.8	32%	65
B101	92.0 – 95.3	3.3	32%	62
	95.0 – 98.3	3.3	39%	64
	98.0 – 101.3	3.3	39 - 52%	66
	100.0 – 103.3	3.3	52%	67
B102	92.0 – 96.8	4.8	29 – 48%	63
	96.0 – 100.8	4.8	48%	66
	100.0 – 104.8	4.8	70%	68

Instrumentation/Quality Control Checks

Attachment C contains a photograph of the packer test skid that was used for the tests, and the magnetic water meter (flow meter). The flow meter registered flow accurately at 0.03 to 6.6 gallons per minute (gpm) and provided a digital display to 0.01 gallons per minute (gpm). The flow rate and total consumed volume outputs were used during the tests. The total consumed volume output registered flow in two directions, which made observation of flow reversal possible. For intervals where no flow was registered, when pressure was applied to the system by restricting the bypass valve, a few seconds of flow downhole could be observed to occur until new pressure equilibrium is reached. Likewise, when pressure was released from the system, flow could be observed to reverse until a new equilibrium was obtained.

The total consumed volume was found to be zero for intervals where no flow occurred. The finding was confirmed with the use of a graduated 300-gallon water tank from which all pumped water was taken and transferred to a separate tank during the injection tests. The drill rig was equipped with a pump system which was used to pump water from the tanks for the packer tests. A grease pen was used to mark the water level in the tank prior to startup of the pump for each test. Upon completion of tests with no flow, the water tank most often indicated the water level had not changed during the test (*e.g.* the test interval did

not consume any water). Where small volumes of water were consumed, the meter reading for total consumed volume was compared to the volume lost from the tank. Where volumes did not match, test data was further evaluated to identify possible sources of system leaks or interferences.

Prior to packer testing, leak tests were performed on the 1-inch diameter steel rod and inflatable packer elements. Several sections of steel rod were connected above ground and water was pumped into the rod under pressure to test the integrity of the threaded pipe joints. Teflon tape was placed on every threaded joint as the packer system was lowered into the hole. Leak tests did not find that threaded joints were a source of leakage.

Inflatable packer elements were leak tested above ground and downhole. Packers were slightly inflated above ground and inspected for cuts and leaks using soapy water. Connections to air supply at the packer and nitrogen gas source tank were also tested. The dual/straddle packer system was then constructed to the 4.8-ft (or 3.3-ft) configuration and lowered downhole where it was inflated against the 4 7/8-inch diameter steel coring casing. Packer elements were inflated to the specifications listed in the manufacturer's technical manual and water was injected through the instrumentation skid against the steel casing. Results of the test confirmed function of the packer elements and water meter (which registered no flow). Water level inside the casing was monitored to double check packer and water meter function.

During packer tests, water levels were also monitored inside of the 4 7/8-inch diameter steel casing to monitor integrity of the packer seal. Slight rise in water level inside the casing during a test can occur when test pressure approaches or exceeds packer inflation pressure. If a rise in water level was observed, the test was stopped. Packer inflation pressures were calculated in the field and adjusted based on maximum test pressures (P_{max}).

Nitrogen tank pressure and packer pressure were monitored above ground during tests at pressure gauges mounted on the nitrogen tank. Loss in either nitrogen tank pressure or packer pressure would be reflected in gauge pressure loss and would indicate a failure of either the supply line or packer element.

Lastly, prior to packer testing (*e.g.* prior to the first packer test), the borehole was flushed with water to clean the borehole of drill cuttings. Water was pumped through the coring rod near the bottom of the borehole, forcing water to rise to the surface. Several hundred gallons of water was pumped until return water was free of suspended material.

Calculations

Table 1 provides a summary of the calculated hydraulic conductivities for the test intervals, including the lowest representative hydraulic conductivity calculated at each boring location (*i.e.,* B100, B101 and B102). Based on current Lugeon interpretation practice described in Camilo Quiñones-Rozo (Quinones-Rozo, C., 2010) and the typical Lugeon patterns that resulted from the series of pressure stages at each testing interval (where the Lugeon values generally decrease as the water pressures increase and the minimum Lugeon value is observed at the stage with the maximum water pressure [P_{max}]), the Lugeon value corresponding to the highest water pressure (P_{max}) was selected as the representative Lugeon value, and hydraulic conductivity, for all testing intervals. These values assumed injection at the lowest recordable flow rate at the highest test pressure (P_{max}) possible without exceeding a downhole pressure greater than maximum packer inflation pressure or exceeding the confinement stress of the bedrock formation.

Hydraulic conductivities are calculated using the following equation (Quinones-Rozo, C., 2010):

Lugeon value = $12.42(Q / L) (P_o / P)$ (cm/s)
Where: Q = flow rate (gpm)
L = length of test interval (ft)
P_o = reference pressure (145 psi [1 MPa])
P = water pressure (psi)
1 Lugeon = 1.3×10^{-5} cm/s

Boring B100

Attachment B contains the field notes for the Lugeon tests that were successfully completed at boring B100. A dual/straddle packer system configured with a 4.8-ft perforated interval was used to complete three tests in the following sequence, beginning with the shallowest interval: 86.0 – 90.8 ft bgs, 90.0 – 94.8 ft bgs, and 95.0 – 99.8 ft bgs (single [top packer] packer test). Water was injected under a maximum pressure (P_{max}) of 60 psi in the shallow interval, 62 psi in the intermediate interval, and 65 psi in the deep interval, none of which accepted flow into the formation. Consistent with Lugeon interpretation practice described in (Quinones-Rozo, C., 2010) when Lugeon values decrease as the water pressures increases the representative Lugeon value (and hydraulic conductivity) corresponds to the highest water pressure (3rd stage [P_{max}]). The results in **Table 1** indicate all but one test exhibited this flow behavior, therefore the general assumption for interpretation of the representative Lugeon values in this Tech Memo is to select the Lugeon value (and hydraulic conductivity) that corresponds to highest water pressure (3rd stage [P_{max}]). The lowest measurable hydraulic conductivity calculated at B100 was <2.3E-06 cm/s recorded from 95.0-99.8 ft bgs, where the lowest measurable hydraulic conductivity is determined by the limits of the equipment (minimum measurable flow rate) and confinement stress of the bedrock formation (P_{max}) (**Table 1**).

Boring B101

Attachment B contains the field notes for the Lugeon tests that were successfully completed at boring B101. A dual/straddle packer system configured with a 3.3-ft perforated interval was used to complete four tests in the following sequence, beginning with the shallowest interval: 92.0 – 95.3 ft bgs, 95.0 – 98.3 ft bgs, 98.0 – 101.3 ft bgs, and 100.0 – 103.3 ft bgs. Water was injected under a maximum pressure (P_{max}) of 62 psi in the shallow interval, which did not accept any water into the formation. Water was injected under a maximum pressure (P_{max}) of 64 psi in the shallow-intermediate interval, which accepted water at a rate of 0.1 gallons per minute (gpm) into the formation. Water was injected under a maximum pressure (P_{max}) of 66 psi in the deep-intermediate interval, which accepted water at a rate of 0.1 gpm. Water was injected under a maximum pressure (P_{max}) of 67 psi in the deep interval, which did not accept any water into the formation. The lowest measurable hydraulic conductivity calculated at B101 was <3.2E-06 cm/s recorded from 100.0-103.3 ft bgs (**Table 1**).

Boring B102

Attachment B contains the field notes for the Lugeon tests that were successfully completed at boring B102. A dual/straddle packer system configured with a 4.8-ft perforated interval was used to complete three tests in the following sequence, beginning with the shallowest interval: 92.0 – 96.8 ft bgs, 96.0 – 100.8 ft bgs, and 100.0 – 104.8 ft bgs. Water was injected under a maximum pressure (P_{max}) of 63 psi in the shallow interval, which did not accept any water into the formation. Water was injected under a maximum pressure (P_{max}) of 66 psi in the intermediate interval, which did not accept any water into the formation. Water was injected under a maximum pressure (P_{max}) of 68 psi in the deep interval, which did not accept any water into the formation. The lowest measurable hydraulic conductivity calculated at B102 was <2.2E-06 cm/s recorded from 96.0-100.8 ft bgs and 100.0 – 104.8 ft bgs (**Table 1**).

SURVEYING

On December 26, 2024 IngenAE, LLC (IngenAE) was contracted to survey boring locations B100, B101, and B102. IngenAE surveyed the coordinates at each location referencing the Illinois West State Plane Coordinate System North American Datum (NAD) 1983. Ground surface elevations were measured at each location using the North American Vertical Datum (NAVD) 1988. The survey report from IngenAE is included in **Attachment D**.

Notes: Bold text indicates representative values selected for testing interval
No Flow = meter's total consumed volume and flow rate outputs/display indicated zero flow for the indicated pressure step.
Hydraulic conductivity values for pressure steps where no flow was observed are shown as less than the calculated hydraulic conductivity at the minimum observable flow rate (0.03 gpm).
gal/min = gallons per minute
psi = pounds per square inch
bgs = below ground surface
cm/s = centimeters per second

Corehole Location	**Depth** (feet,bgs)	**Elevation** (feet NAVD88)	**Q Injection Rate** (gal/min)	**Lugeon Test Step**	**P Gauge Pressure** (psi)	**L Test Interval** (feet)	**Q / L** (gal/min/feet)	**Hydraulic Conductivity (K)** (ft/min)	**P_o / P** (psi)	**Hydraulic Conductivity** (Lugeons)	**Hydraulic Conductivity** (cm/s)
Lowest Measurable Hydraulic Conductivity											
B100	95.0 - 99.8	354.73 - 349.93	<0.03	C	65	4.8	<0.006	2.0E-06	2.2	<1.7E-01	<2.3E-06
B101	100.0 - 103.3	359.29 - 355.99	<0.03	C	67	3.3	<0.009	2.0E-06	2.2	<2.4E-01	<3.2E-06
B102	96.0 - 100.8	358.97 - 354.17	<0.03	C	66	4.8	<0.006	2.0E-06	2.2	<1.7E-01	< 2.2E-06

Notes: Lowest measureable hydraulic conductivity was calculated assuming minimum observable flow rate at maximum test pressure; maximum test/gauge pressue depends on test depth and maximum packer inflation pressure.
The 96.0 - 100.8 foot interval from B102 was selected as the lowest measureable hydraulic conductivity because it is the closer interval to the ground surface.

Lugeon Test Data Sheets

Packer / Injection Test Field Data Form

Site: Hennepin Power Plant	Project Number:	1940110419	Page 1 of 2
Field Personnel: EGP, LCA	Weather Conditions: 63 deg F/ Cloudy Windy		
Drilling Subcontractor: Cascade	LS450 - Sonic		
Lead Driller: Todd Schmalfeldt	Driller's Helper: Paul, Jeff		
Borehole ID: B100	**Depth/Packer Interval: 86-90.8'**		
Static Water Level: 4.20	**Packer Inflation (psi): 200**		

Packer Specs**:** TAM International packer elements: 3.5"-dia at rest; 6" max inflated dia; unconfined pressure rating: 65 psi; max inflation pressure: 350 psi

Site-specific construction: total length of dual/straddle assembly: 10' 1/4"; length of perforated interval - 4'10"; depth to top of bottom packer: 90.8'; depth to bottom of upper packer: 86.0; borehole dia: 4 7/8" (HQ barrel)

Packer Inflation = [(0.43 x Depth to Packer, ft) + unconfined pressure rating, psi + injection pump pressure, psi] x 1.1
(i.e. at 150 ft depth and 100 psi injection pressure: inflation pressure = [(0.43 x 150) + 65 + 100] x 1.1 = 200 psi

Date: 10/31/24 Start Time: 9:46

1. INTRODUCTION

This report is an addendum to the geochemical conceptual site model (GCSM) for the Hennepin Power Plant (HPP) West Ash Pond System (WAPS) coal combustion residuals (CCR) unit (Unit #804) with the results of an additional investigation to further characterize the site. The initial GCSM described the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment at the WAPS (Geosyntec 2024). The initial GCSM was prepared as an appendix to the HPP WAPS Nature and Extent (N&E) Report prepared by Ramboll Americas Engineering Solutions. Inc. (Ramboll) and submitted to the Illinois Environmental Protection Agency (IEPA) on 8 May 2024 (Ramboll 2024). Subsequent to the N&E report submittal, an additional investigation was conducted to further characterize the site, including the following:

- Collection of solids samples from two intervals at boring B100, which was advanced immediately adjacent to well 21R in October 2024, and
- Collection of groundwater samples from wells 21R, 34, and 51 in September 2024.

The additional groundwater samples were collected to further characterize aqueous arsenic speciation at locations with arsenic concentrations above the groundwater protection standard (GWPS) (wells 21R and 51) and background well 34. Similarly, solids samples were collected adjacent to 21R to better characterize the aquifer solids at relevant WAPS compliance monitoring locations.

Parameters with exceedances[1] above the GWPS at the Hennepin WAPS for the second, third, and fourth quarters of 2024 sampling events completed under Illinois Administrative Code (I.A.C.) Title 35 § 845.630 are arsenic, boron, lithium, total dissolved solids (TDS) and sulfate. Exceedances of arsenic and boron were reported at compliance monitoring well 21R and for arsenic at well 51. Therefore, arsenic and boron are the constituents of concern in the western portion of the site; however, only arsenic is considered in this addendum due to the targeted nature of the additional sampling completed in 2024 and because boron concentrations have continued to decrease at well 21R. Both well 21R and well 51 are screened within the Uppermost Aquifer Unit (UAU) hydrostratigraphic unit (HSU).

[1] Throughout this document, “exceedance” or “exceedances” is intended to refer only to potential exceedances of proposed applicable background statistics or groundwater protection standards (GWPSs) as described in the proposed groundwater monitoring program which was submitted to the IEPA on October 25, 2021 as part of Dynegy Midwest Generation, LLC’s operating permit application for the WAPS. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and therefore Dynegy Midwest Generation, LLC has not identified any actual exceedances.

2. UPDATES TO THE GEOCHEMICAL CONCEPTUAL SITE MODEL

The HPP WAPS GCSM (Geosyntec 2024), which was submitted as Appendix B to the N&E Report (Ramboll 2024) provided an overview of the geochemical conditions at the HPP WAPS. This addendum provides details on the additional investigation samples collected in 2024 and an interpretation of how these samples align with or modify the GCSM for the Site provided in the 2024 GCSM document. Unless otherwise specified, the discussion that follows is focused on samples collected from monitoring well locations included in the targeted additional investigation sampling.

2.1 Constituent Transport and Fate

Arsenic speciation in groundwater is dependent on both pH and oxidation/reduction (redox) reactions and is typically present as arsenic (III) or arsenic (V) in environmental systems. Arsenic (III) is the predominant species under relatively reducing conditions and, at pH values less than 9 standard units (SU), forms the neutral complex $As(OH)_3$. Arsenic (V) is the predominant species under relatively oxidizing conditions and typically exists as $HAsO_4^{2-}$ at pH values above 7 SU and as H_2AsO4^- at pH values less than 7 SU. Arsenic (V) is more likely to be attenuated than neutral arsenic (III) species due to its negative charge and electrostatic interactions with soil/aquifer solids. In general, arsenic has a high sorption affinity for metal (i.e., aluminum, iron, and manganese) oxyhydroxides and may also sorb to clay minerals (Rahman et al. 2019, Nguyen et al. 2021). Arsenic sorption is typically favored at lower pH values where electrostatics enhance attenuation to material surfaces, and also under oxidizing conditions due to the greater propensity for attenuation of the negatively charged $HAsO_4^{2-}$ species relative to neutral $As(OH)_3$ species. Further, the presence of divalent cations (such as calcium [Ca^{2+}]) can promote arsenic (V) absorption (Nguyen et al. 2021).

2.2 Solids Characterization

Additional solids were characterized to determine the type and abundance of minerals present in the UAU, their geochemical properties, and their effect on the geochemistry of the groundwater system. Solids were collected from boring B100, which was located to the west of the Old West Polishing Pond and immediately adjacent to monitoring well 21R. Solids were collected from two intervals (37 to 38 feet below ground surface [bgs] and 48 to 49 ft bgs) within the UAU, representing an upper sandy silt interval and a lower gravel interval with silty/clayey interlayers.

The monitoring well locations and the location of B100 are shown on Attachment A. The boring log for B100 is provided in Attachment B.

2.2.1 Loss on Ignition and Cation Exchange Capacity

Total organic carbon (TOC) represents only the carbon component of organic matter within a solid material, while loss on ignition (LOI) represents the combustible portions of a solid material and

is often used as an approximation of organic matter in a sample. The TOC and LOI values for solids are presented in Table 1 and laboratory analytical results are provided in Attachment C.[2]

TOC values for the B100 samples ranged from <0.11% to 2.5%, while LOI ranged from 0.8 to 6.4%. Both TOC and LOI were relatively lower in the B100 samples compared to those previously analyzed in the same UAU HSU (TOC of 0.34 to 4.6%; LOI of 11.6 to 21.5%; Table 1); suggesting that there is more variable organic matter content within UAU solids than previously thought. This variability is of particular note as solids from SB-51, advanced adjacent to the other monitoring network location with an exceedance of arsenic, has relatively high levels of organic matter considered more aligned with the reducing conditions typically associated with elevated arsenic concentrations.

2.2.2 Total Metals via Bulk Characterization

Total metals were analyzed to determine the major and trace metal content of aquifer solids with results presented in Table 2, and laboratory analytical results in Attachment C. For B100, analysis was completed for total arsenic, aluminum, iron, and manganese. Arsenic was detected in B100 solids at concentrations similar to previous site solids, ranging from 2.3 to 4.6 micrograms per gram (µg/g). Aluminum concentrations were greater in solids from B100 (8,700 to 30,000 µg/g) than any previously analyzed solids, while iron (4,800 to 12,000 µg/g) and manganese (120 to 300 µg/g) concentrations had overlapping ranges with other UAU solids. The presence of these metals (aluminum, iron, and manganese) in the aquifer solids at B100 at similar concentrations provides support that these metals may provide potential attenuation sites for arsenic in the form of metal oxyhydroxides, consistent with the conclusions of the prior GCSM.

2.2.3 Sequential Extraction Procedure Analysis of Metals

Material from each of the two intervals for B100 samples were submitted for sequential extraction procedure (SEP) for metals. SEPs are chemical extractions used to dissolve metals from specific solid-associated phases. SEPs use progressively stronger reagents to solubilize metals from increasingly recalcitrant phases. Although these procedures do not identify the discrete solid phases in a soil/aquifer matrix, they do provide a means to evaluate the class of solids and relative stability in relation to general solubility, changes in redox potential, and pH fluctuations (Tessier et al. 1979, Kuo et al. 1983, Sposito et al. 1984, Hickey and Kittrick 1984, Gruebel et al. 1988). Therefore, SEP data are useful to infer the mechanism and potential reversibility of attenuation processes. The results of the 7-step extraction procedure and analysis are provided in Table 3 and Attachment C. Solids samples from previous investigations (e.g. SB-34, SB-51) were analyzed for metal association via SEP by a different 6-step extraction procedure (as reported in Geosyntec 2024); therefore, the results are not directly comparable to the additional investigation samples.

[2] Analytical laboratory reports are only provided for the additional data collected in 2024. For additional data that was previously collected and is shown within table for comparison, the analytical data were provided as attachments to the GCSM (Geosyntec 2024).

Arsenic in aquifer solids from B100 was bound predominantly to the residual phase (42 to 44%). Arsenic was also bound to the metal oxide phase (0.38 to 0.69 µg/g [16% and 14%, respectively]), which includes crystalline iron and manganese oxides, to the non-crystalline materials (including amorphous metal oxides; 0.29 to 1.0 µg/g [12% and 21%, respectively]) and to sulfides (0.67 to 0.94 µg/g [20% and 28%, respectively]). B100 solids therefore had arsenic bound to metal oxides, both amorphous and crystalline, at relative distributions that are within the same range as those previously detected for SB-34 and SB-51. This suggests that iron and manganese oxides in these solids have some capacity to serve as adsorption sites for arsenic, but at a lower capacity than at other locations within the UAU. Overall, these results suggest some attenuation via interaction with metal oxides may be feasible in the aquifer. The sum of the arsenic measured in the SEP extractions (Table 3) was well correlated with the reported total arsenic concentrations in the solid samples (Table 2).

As with previous samples, aluminum within SB100 solids was almost exclusively associated with the residual metal phase (i.e., clays and feldspars), indicating that aluminum oxides could contribute to the sorptive capacity of solids within the aquifer. Iron was primarily detected in solid fractions associated with non-crystalline materials, oxides, sulfides and residual metal phases. Between 20% and 24% of the iron extracted from the aquifer solids was associated with the oxide phase, indicating that iron oxides are present at significant concentrations and may provide potential sorption sites for arsenic, consistent with previously analyzed aquifer solids. Manganese was primarily detected in solid fractions associated with carbonates, metal oxides, and non-crystalline materials, with lesser amounts bound to residual metals, a distribution similar to previously analyzed UAU solids.

2.2.4 Mineralogical Analysis

X-Ray diffraction (XRD) with Rietveld refinement was conducted for identification of minerals in aquifer solid samples. XRD is an analytical technique that provides information about the identity of the crystalline material within a sample but does not provide information about non-crystalline or amorphous phases. XRD results are normalized to 100% of the total weight, meaning that material not characterized by XRD is ignored in the percent calculation.

B100 sample solids from the UAU were predominantly composed of quartz, ranging from 60.9 to 87.6% of the minerals present (Table 4; Attachment D)[3]. B100 had a higher quartz content than the previously analyzed samples (Geosyntec 2024). Feldspar minerals (4.2 to 8.7%), carbonates including dolomite and calcite (1.1 to 11.4% total), and clays identified as chlorite, kaolinite and illite/muscovite (0 to 7.2% total) were identified as additional primary crystalline mineral phases. These results are consistent with the field observations documented in the boring log provided in Attachment B. Unlike previously analyzed UAU solids with low abundances of magnetite

[3] 2021 solids samples included in the GCSM were analyzed by SGS Minerals (Ontario, Canada), whereas 2024 samples were analyzed by Eurofins J3 Resources, Inc. (Pasadena, Texas). Due to differences in analytical reporting methodology, only 2024 samples are presented in Table 4.

(detected to 0.5%) detected (Geosyntec 2024), no crystalline forms of iron oxides were detected in B100 sample solids. When considered with the SEP analyses that indicated that the iron present in B100 sample solids was present relatively equally within the crystalline and amorphous metal oxide fractions and the previous XRD analyses, both amorphous and crystalline iron oxides are likely important sorption surfaces at UAU locations.

2.3 Aqueous Characterization

Monitoring well locations in the vicinity of the WAPS are shown in Attachment A. Groundwater at both wells with arsenic GWPS exceedances (21R and 51) and background well 34 was sampled in September 2024 for analysis of aqueous arsenic speciation and select aqueous metals (total and dissolved). Results of both analyses are provided in Tables 5 and 6, respectively.

2.3.1 Exceedance Parameters

Boron groundwater concentrations are declining at both 21R and 51, with recent results below the GWPS at both locations (Figure 1). The historically elevated boron concentrations suggest that there may have been previous influence of porewater at 21R and 51. Arsenic concentrations in groundwater remain in exceedance of the GWPS at 21R and 51, consistent with the prior GCSM (Geosyntec 2024). Arsenic concentrations in groundwater at 21R and 51 generally appear stable and above the concentrations reported at background well 34 (Figure 2). As arsenic concentrations exhibit a different behavior from boron, this suggests a potential ongoing source to groundwater either from geogenic arsenic or the effect of previously sorbed arsenic that was attenuated via interaction with aquifer solids.

2.3.2 Redox/pH Summary

The redox potential and pH in aqueous systems are major controls on the speciation of redox-active chemicals such as iron, manganese, and arsenic. UAU groundwater had previously varied between 6.8 to 7.7 standard units (SU) at all wells in the network, with slightly higher pH values observed along the north side of the WAPS compared to background (Geosyntec 2024). The September 2024 groundwater samples fell within the same range previously documented for UAU groundwaters (Table 5).

Redox conditions were found to vary across the site, with the east side of the WAPS generally exhibiting more oxidizing conditions and the west side exhibiting more reducing conditions (Geosyntec 2024). The September 2024 ORP field measurements at the wells of interest were reducing (-133 to -174 millivolts), which was consistent with previous results. The consistently reducing conditions at 21R and 51 remain aligned with the elevated arsenic concentrations detected at these wells.

2.3.3 Exceedance Parameters: Arsenic Speciation

Aqueous arsenic concentrations were reported to be approximately two orders of magnitude lower at background well 34 compared to wells 21R and 51 with exceedances, based on total arsenic concentrations (Table 6) and arsenic speciation analyses (Table 5). While aqueous arsenic at background well 34 was nearly evenly comprised of arsenite (arsenic with a 3+ oxidation state)

and arsenate (arsenic with a 5+ oxidation state), arsenite was reported as the dominant oxidation state in wells 21R and 51 (Table 5). Arsenic speciation results reflect the higher arsenic concentrations at the wells with exceedances compared to the nearest background locations and indicate that arsenite, the more mobile oxidation state of the two, dominates aqueous arsenic at these locations.

2.3.4 Pourbaix Diagrams

Eh-pH, or Pourbaix, diagrams can be used to illustrate the predicted stability of specific phases at thermodynamic equilibrium under the conditions observed for a groundwater sample. Select crystalline mineral species were suppressed to be representative of anticipated groundwater conditions (e.g. mineral formation not anticipated to be kinetically favored), except when identified in XRD data from solids in the site. Conditions detected at well 21R on 8 October 2024 were used to represent wells from the 2024 groundwater sampling effort, which tend to be more reducing than other well locations in the monitoring network (Table 7).[4] To make groundwater samples comparable to previously analyzed GCSM data, field measured Eh values were utilized to generate Pourbaix diagrams.

Crystalline magnetite is expected to be stable at the relevant groundwater sample locations (Figure 3), which is consistent with the low abundances of magnetite detected in aquifer solids at nearby locations via XRD analysis at abundances ranging between 0.2 and 0.5 wt% (Table 4); however, magnetite was not identified in solids from B100. When magnetite is suppressed, amorphous iron oxyhydroxides (represented by ferrihydrite) are generally not predicted to be stable in the aquifer at locations with reducing conditions (Figure 4). This contrasts with monitoring wells on the eastern side of the site, which exhibited greater stability of iron oxides overall due to varying redox conditions, as noted in the May 2024 GCSM (Geosyntec 2024). Ankerite, which is represented by siderite in Figures 1 and 2 (as a similar iron-containing carbonate), may be stable under reducing conditions (Figure 2). Siderite stability is consistent with XRD detection of ankerite in aquifer solids at abundances ranging from 1.3 to 6.0 wt% at nearby locations (Table 4); however, no crystalline iron carbonates were detected in solids from B100. A review of Eh-pH conditions for manganese found that solid phase manganese minerals, including manganese oxides, are not predicted to be stable under conditions within the UAU for the relevant groundwater sampling locations (Figure 5).

Arsenic in groundwater samples is predicted to primarily exist as the arsenic (V) species $HAsO_4^{2-}$ using field-measured ORP values, even under reducing aquifer conditions that predominate at well 21R (Figure 6). However, the arsenic speciation results (Section 2.3.2) contrast with the existing GCSM for arsenic at 21R and 51, which posited that arsenate species may be more prevalent at these locations. Recently collected data indicate that the consistently reducing conditions at these wells are associated with arsenic speciation favoring more mobile species (i.e., arsenite), a trait

[4] Field ORP measurements were converted to Eh by adding +200 millivolts to correct for the Ag/AgCl electrode.

which is likely exclusive to the highly reducing, organic-rich lithology underlying the western portion of the WAPS.

2.3.5 Illinois River Water Sampling

Samples were previously collected from the Illinois River via the shoreline of the site immediately adjacent to the WAPS to help characterize local conditions, as groundwater monitoring has indicated occasional reversal of groundwater flow direction at well 22 (located on the eastern portion of the site) due to elevated river levels associated with flooding events. As this addendum is focused on the western portion of the site, these results are not discussed herein but are provided in Attachment E to complete the documentation of relevant analytical data associated with the site.

3. EXTENSION AND MODIFICATION OF GEOCHEMICAL SITE CONDITIONS

3.1 Source and Mobilization Mechanisms

Arsenic is naturally present within coals and is concentrated within CCR. Arsenic exhibited elevated concentrations in CCR porewater from the WAPS at the time of collection in 2017. Given the historical boron concentrations and decreasing trends relative to arsenic concentration trends at the wells of concern, there may have been previous influence of porewater on the UAU solids near wells 21R and 51. However, arsenic was detected within UAU aquifer solids from both compliance and background well locations, which is supportive of a naturally occurring geogenic source of arsenic. Therefore, previous impacts from CCR porewater and native geological material are both potential sources of arsenic to groundwater.

3.2 Potential and Observed Attenuation Mechanisms

The results of the additional investigation sampling modify the potential and observed attenuation mechanisms for arsenic described in the previously submitted GCSM. Speciation analysis indicates that the neutral arsenite species is predominant at compliance wells (21R and 51) with arsenic GWPS exceedances. Arsenite is expected to be generally more mobile, with lower affinity for sorption onto metal (oxy)hydroxides, which combined with the lowered stability for metal (oxy)hydroxides at these locations, is likely leading to a degree of arsenic desorption (whether geogenic or from prior CCR porewater influences) at locations within the highly reducing, organic-rich lithology underlying the western portion of the WAPS. While the primary mechanism of potential arsenic attenuation remains sorption onto iron oxides and oxyhydroxides associated with solids throughout the UAU (as supported by SEP results demonstrating that between a quarter and a third of all arsenic is associated with metal oxide phases), this mechanism is likely not prevalent to the same degree in locations with reducing conditions.

Field Boring Description			Sandy Silt	Gravel with some silty/clayey layers
Mineral/Compound	**Formula**	**Mineral Type**	**(wt %)**	**(wt %)**
Quartz	SiO_2	Silicate	60.9	87.6
Calcite	$CaCO_3$	Carbonate	7.3	1.1
Feldspar	$(Ca,Na)Si_3O_8$	Feldspar	8.7	4.2
Illite/Muscovite	$KAl_2(AlSi_3O_{10})(OH)_2$	Clay/Mica	7.2	pp
Dolomite	$CaMg(CO_3)_2$	Carbonate	11.4	7.1
Kaolinite	$Al_2Si_2O_5(OH)_4$	Clay	2.0	ND
Chlorite	$(Fe,(Mg,Mn)_5,Al)(Si_3Al)O_{10}(OH)_8$	Clay	2.6	ND

Notes
Sample depth is shown in feet below ground surface (ft bgs)
pp - possible presence; mineral may be present in the sample but its indentification is not definitive.
wt % - percentage by weight
ND - not detected in the sample

Table 5 - Arsenic Speciation Groundwater Redox Summary *Geosyntec Consultants, Inc.*
Geochemical Conceptual Site Model
Hennepin West Ash Pond System, Illinois

Monitoring Well		34	21R	51
Type		Background	Compliance	Compliance
Date	Units	9/12/2024	9/12/2024	9/12/2024

Job Notes

This report may not be reproduced except in full, and with written approval from the laboratory. The results relate only to the samples tested. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

The test results in this report relate only to the samples as received by the laboratory and will meet all requirements of the methodology, with any exceptions noted. This report shall not be reproduced except in full, without the express written approval of the laboratory. All questions should be directed to the Eurofins TestAmerica Project Manager.

Qualifiers

Metals

Qualifier	Qualifier Description
*-	LCS and/or LCSD is outside acceptance limits, low biased.
B	Compound was found in the blank and sample.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
☼	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job Narrative
140-39235-1

Receipt
The samples were received on 10/29/2024 at 9:30am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 0.5º C.

Receipt Exceptions
The Field Sampler was not listed on the Chain of Custody.

GC Semi VOA
Method Lloyd Kahn: Please note that the reporting limit for Lloyd Kahn TOC analysis is a nominal value and does not reflect adjustments in sample mass processed on an individual basis
HEN-B100-37-38 (140-39235-1), HEN-B100-48-49 (140-39235-2), (180-181930-A-3), (180-181930-A-3 MS) and (180-181930-A-3 MSD)

Method Lloyd Kahn: The matrix spike / matrix spike duplicate (MS/MSD) recoveries for analytical batch 180-483870 were outside control limits for one or more analytes. See QC Sample Results for detail. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample (LCS) recovery is within acceptance limits.

Method Lloyd Kahn: The sample duplicate precision for the following sample associated with analytical batch 180-483870 was outside control limits however, the sample is ND and therefore results have been reported: HEN-B100-48-49 (140-39235-2).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Job ID: 140-39235-1 (Continued)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

Method 6010B SEP: The LCS/LCSD recoveries for Arsenic were outside advisory limits. Samples were non-detect for this analyte. The LCS/LCSD for this prep step is known to have low recoveries as the limits are 60% to 100%. The slightly low recoveries of 56% and 50% do not significantly impact the data; therefore, the samples are reported.

HEN-B100-37-38 (140-39235-1), HEN-B100-48-49 (140-39235-2), (LCS 140-93113/5-B ^5) and (LCSD 140-93113/6-B ^5)

Methods 6010B, 6010B SEP: The following samples were diluted due to the presence of Silicon which interferes with Arsenic: HEN-B100-37-38 (140-39235-1), HEN-B100-48-49 (140-39235-2), (140-39235-B-1-D DU) and (140-39235-B-1-V DU). Elevated reporting limits (RLs) are provided.

Methods 6010B, 6010B SEP: The following samples were diluted due to the nature of the sample matrix: HEN-B100-37-38 (140-39235-1), HEN-B100-48-49 (140-39235-2), (140-39235-B-1-D DU) and (140-39235-B-1-V DU). Elevated reporting limits (RLs) are provided for Aluminum.

Methods 6010B, 6010B SEP: The serial dilution performed for the following samples associated with batch 140-93606 was outside control limits: HEN-B100-37-38 (140-39235-1), (140-39235-B-1-C SD ^5) and (140-39235-B-1-U SD ^5)

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	N/A	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	N/A	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	True	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

Analyst: Carlos Duane Salinas

Eurofins Built Environment Testing (EBET) is an analytical laboratory accredited for the analysis of asbestos in air and bulk samples by X-Ray Powder Diffraction (XRD), Analytical Transmission Electron Microscopy (ATEM), and Polarized Light Microscopy (PLM) by the National Voluntary Laboratory Accreditation Program (NVLAP) {Lab Code 200525 (Houston) and Lab Code 600120 (Pasadena)}, and the American Industrial Hygiene Association Lab Code 157714 (Pasadena)}.

All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. The results relate only to the samples as received and tested. The results include an inherent uncertainty of measurement associated with estimating percentages by the analytical method utilized.

Eurofins Built Environement Testing located in Pasadena, TX, a member of the Eurofins Built Environment Testing group of companies, shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. Dear Kristyn,

Eurofins Built Environmental Testing (EBET) is an analytical laboratory accredited for the analysis of asbestos in air and bulk samples by X-Ray Powder Diffraction (XRD), Analytical Transmission Electron Microscopy (ATEM), and Polarized Light Microscopy (PLM) by the National Voluntary Laboratory Accreditation Program (NVLAP) {Lab Code 200525 (Houston) and Lab Code 600120 (Pasadena)}, and the American Industrial Hygiene Association Laboratory Accreditation Program (AIHA LAP,LLC) {Lab Code 157714 (Pasadena)}.

EBET received two (2) samples on October 30, 2024, to determine their mineralogy by X-Ray Powder Diffraction (XRD). The samples were a gray colored sandy clay, and a tan sand contained in individually labeled and sealed 4 oz clear glass jars. The chain of custody matched the labeled sample ID's as follows:

Client Sample Number	EMLab ID Number
HEN-B100-37-38	3833465-1
HEN-B100-48-49	3833465-2

EBET prepped and analyzed the samples using X-Ray Powder Diffraction.

3833465 is the job number assigned to this study. This report is considered highly confidential and the sole property of the customer. EBET will not discuss any part of this study with personnel other than those authorized by the client. The results described in this report only apply to the samples analyzed. This report shall not be reproduced except in full, without written approval from EBET. The sample will be kept in our secure storage facility for a minimum of three (3) months from the report date.

eurofins | Built Environment Testing

Full Mineral Scan Sample Preparation

A representative grab sample of the soil was dried overnight at 110 degrees Celsius in our drying oven. The dried sample was then crushed using a large mortar and pestle. The crushed sample was coned and quartered to acquire a representative sample to be further prepared. This sample was ground and homogenized by hand using a mortar and pestle, and then passed through a No. 35 Tyler Mesh (500 um) sieve. The sieved sample was then milled in a McCrone XRD Micro Mill for 15 minutes, utilizing agate grinding elements to produce a powder that was prepped and scanned in our Cubix3/Panalytical XRD using a mineral scan program.

The results of this study can be found in the attached documents. If you should have any questions about this report, please feel free to call us at 713-290-0223.

Sincerely,

Carlos Duane Salinas
Technical Expert
EBET – Pasadena, Texas

Mineralogy Report – November 2024.

This report was prepared at the request of Carlos Salinas, Technical Expert at Eurofins Built Environment Testing

I. Quantitative XRD analysis of powder samples

Table 1 - Scans of the following samples were evaluated.

Sample ID	
3465-1~1	Soil sample
3465-2~1	Soil sample

For QXRD analysis the software High score plus version 2.0.1 available from Malvern Panalytical was used.

II. Instrument and measurement conditions

Cubix3/PANalytical

Instrument settings:
Tube: Ceramic Cu long fine focus
Radiation: Copper (Cu)
Diffractometer radius: 200mm
Sample stage: Sample spinner stage

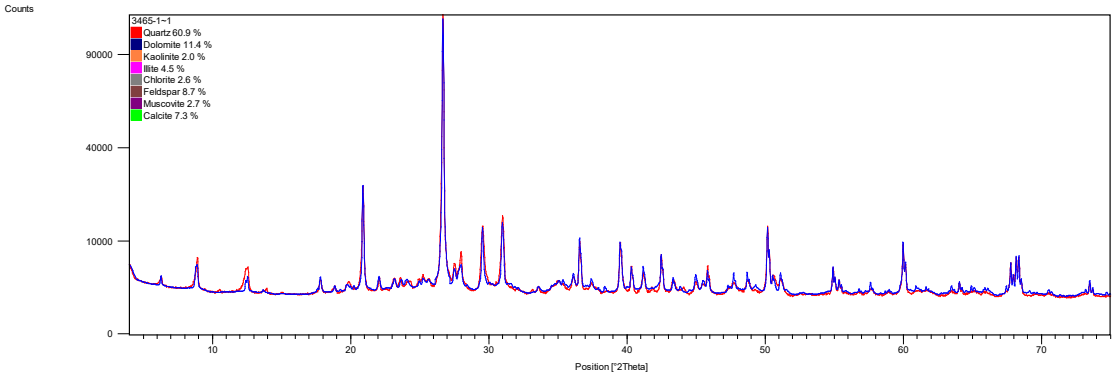
Incident optics:
BBHD
Divergence slit: Fixed 1/2 °
Soller slit: 0.04 radians
Mask: 10mm
Anti scatter slit: Fixed 2°

Diffracted optics:
Soller slit: 0.04 radians
Filter: Not present
Anti scatter slit: Fixed 5.5°
Detector: X'Celerator

Measurement conditions:
Applied power: 45KV, 40mA
Scan range: 4-75º 2Theta
Step size 0,016 º 2Theta
Time per step: 4.82sec
Scan type: continuous

III. QXRD analysis of samples:

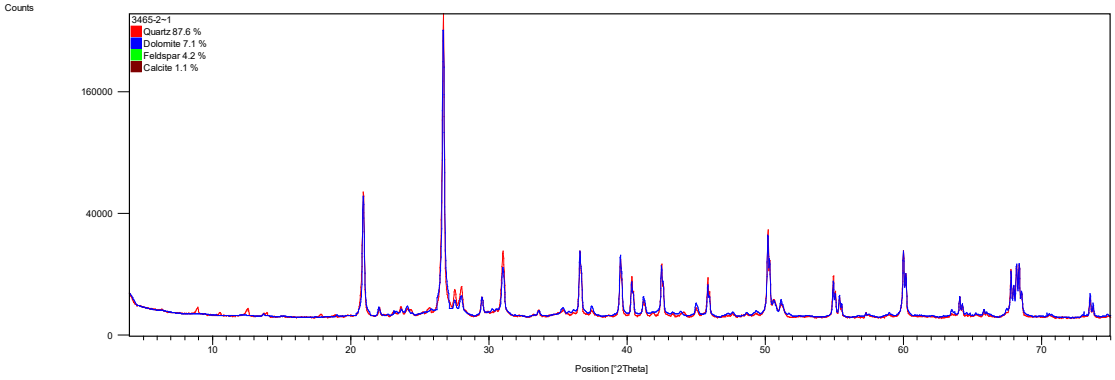
1) Sample 3465-1~1



Phase	Formula	%
Quartz	SiO2	60.9
Dolomite	CaMg(CO3)2	11.4
Feldspar	(Na,Ca)(Si,Al)4O8	8.7
Illite/Muscovite	(K,H3O)(Al,Mg,Fe)2(Si,Al)4O10[(OH)2,(H2O)	7.2
Chlorite/Vermiculite	(Mg,Fe)5Al(Si3Al)O10(OH)8	2.6
Kaolinite	Al2Si2O5(OH)4	2.0
Calcite	CaCO3	7.3

Figure 1 – Results of X-ray diffraction – 3465-1~1

2) Sample 3465-2~1



Phase	Formula	%
Quartz	SiO2	87.6
Dolomite	CaMg(CO3)2	7.1
Feldspar	(Na,Ca)(Si,Al)4O8	4.2
Illite/Muscovite	(K,H3O)(Al,Mg,Fe)2(Si,Al)4O10[(OH)2,(H2O)	pp
Calcite	CaCO3	1.1

Figure 2 – Results of X-ray diffraction - 3465-2~1

3) All samples comparison

	Quartz	Dolomite	Kaolinite	Illite	Chlorite	Feldspar	Muscovite	Calcite
3465-1~1	60.9	11.4	2.0	4.5	2.6	8.7	2.7	7.3
3465-2~1	87.6	7.1	-	-	-	4.2	-	1.1

Figure 3 - The comparison of the x-ray diffraction (XRD) results

IV. Comments

Sample 1 showed the presence of quartz, dolomite, feldspar, calcite, mica, and clay. In sample 2, only quartz, dolomite, feldspar, and calcite were detected, with a possible presence of mica.
The term “possible presence” in XRD interpretation indicates that the mineral may be present in the sample, but its identification is not definitive due to factors such as low concentration, peak overlap, poor crystallinity, or ambiguities in the diffraction pattern. It is necessary to validate the quantification by XRD with other techniques, preferably chemical analysis. The orientation of clay mineral particles affects the XRD intensities of powdered samples. Clay mineral particles exhibit platy characteristics, and some preparation methods can often produce preferred orientation of clay minerals

RE: Hennepin GW **WorkOrder:** 21030004

Dear Allison Kreinberg:

TEKLAB, INC received 4 samples on 3/1/2021 8:22:00 AM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Elizabeth A. Hurley

Quality Control Results	14
Receiving Check List	23
Chain of Custody	Appended

Client: Geosyntec Consultants **Work Order:** 21030004

Client Project: Hennepin GW **Report Date:** 31-Mar-21

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Client: Geosyntec Consultants **Work Order:** 21030004

Client Project: Hennepin GW **Report Date:** 31-Mar-21

Qualifiers

- # - Unknown hydrocarbon
- B - Analyte detected in associated Method Blank
- C - RL shown is a Client Requested Quantitation Limit
- E - Value above quantitation range
- H - Holding times exceeded
- I - Associated internal standard was outside method criteria
- J - Analyte detected below quantitation limits
- M - Manual Integration used to determine area response
- ND - Not Detected at the Reporting Limit
- R - RPD outside accepted recovery limits
- S - Spike Recovery outside recovery limits
- T - TIC(Tentatively identified compound)
- X - Value exceeds Maximum Contaminant Level

ANALYTICAL RESULTS

PERFORMED BY

Pace Analytical Gulf Coast
7979 Innovation Park Dr.
Baton Rouge, LA 70820
(225) 769-4900

Report Date 03/30/2021

Report # 221032623

Project 21030004

Deliver To	***Additional Recipients***
Elizabeth Hurley Teklab, Inc 5445 Horseshoe Lake Road Collinsville, IL 62234 618-344-1004	NONE

Laboratory Endorsement

Sample analysis was performed in accordance with approved methodologies provided by the Environmental Protection Agency or other recognized agencies. The samples and their corresponding extracts will be maintained for a period of 30 days unless otherwise arranged. Following this retention period the samples will be disposed in accordance with Pace Gulf Coast's Standard Operating Procedures.

Common Abbreviations that may be Utilized in this Report

ND	Indicates the result was Not Detected at the specified reporting limit
NO	Indicates the sample did not ignite when preliminary test performed for EPA Method 1030
DO	Indicates the result was Diluted Out
MI	Indicates the result was subject to Matrix Interference
TNTC	Indicates the result was Too Numerous To Count
SUBC	Indicates the analysis was Sub-Contracted
FLD	Indicates the analysis was performed in the Field
DL	Detection Limit
LOD	Limit of Detection
LOQ	Limit of Quantitation
RE	Re-analysis
CF	HPLC or GC Confirmation
00:01	Reported as a time equivalent to 12:00 AM

Reporting Flags that may be Utilized in this Report

J or I	Indicates the result is between the MDL and LOQ
J	DOD flag on analyte in the parent sample for MS/MSD outside acceptance criteria
U	Indicates the compound was analyzed for but not detected
B or V	Indicates the analyte was detected in the associated Method Blank
Q	Indicates a non-compliant QC Result (See Q Flag Application Report)
*****	Indicates a non-compliant or not applicable QC recovery or RPD – see narrative
E	Organics - The result is estimated because it exceeded the instrument calibration range
E	Metals - % diference for the serial dilution is > 10%
L	Reporting Limits adjusted to meet risk-based limit.
P	RPD between primary and confirmation result is greater than 40
DL	Diluted analysis – when appended to Client Sample ID

Sample receipt at Pace Gulf Coast is documented through the attached chain of custody. In accordance with NELAC, this report shall be reproduced only in full and with the written permission of Pace Gulf Coast. The results contained within this report relate only to the samples reported. The documented results are presented within this report.

This report pertains only to the samples listed in the Report Sample Summary and should be retained as a permanent record thereof. The results contained within this report are intended for the use of the client. Any unauthorized use of the information contained in this report is prohibited.

I certify that this data package is in compliance with The NELAC Institute (TNI) Standard 2009 and terms and conditions of the contract and Statement of Work both technically and for completeness, for other than the conditions in the case narrative. Release of the data contained in this hardcopy data package and in the computer readable data submitted has been authorized by the Quality Assurance Manager or his/her designee, as verified by the following signature.

Estimated uncertainty of measurement is available upon request. This report is in compliance with the DOD QSM as specified in the contract if applicable.

Authorized Signature

Case Narrative

Client: Teklab Inc **Report:** 221032623

Pace Analytical Gulf Coast received and analyzed the sample(s) listed
on the Report Sample Summary page of this report. Receipt of the sample(s) is documented
by the attached chain of custody. This applies only to the sample(s) listed in this report.
No sample integrity or quality control exceptions were identified unless noted below.

No anomalies were found for the analyzed sample(s).

PLEASE NOTE:

NELAP accreditation is required on the requested analytes and must be documented as such on the final report. If your laboratory does not currently hold a NELAP accreditation for the requested method and/or analytes, please contact Teklab immediately. If your laboratory loses accreditation or is suspended for any analyte/method during the life of the contract, you must contact Teklab immediately.

RE: GLP8020 **WorkOrder:** 21030443

Dear Allison Kreinberg:

TEKLAB, INC received 9 samples on 3/5/2021 1:55:00 PM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Aaron Renner
Project Manager

Client Project: GLP8020 **Report Date:** 08-Apr-21

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Client: Geosyntec Consultants
Work Order: 21030443
Client Project: GLP8020
Report Date: 08-Apr-21

Qualifiers

# - Unknown hydrocarbon	B - Analyte detected in associated Method Blank
C - RL shown is a Client Requested Quantitation Limit	E - Value above quantitation range
H - Holding times exceeded	I - Associated internal standard was outside method criteria
J - Analyte detected below quantitation limits	M - Manual Integration used to determine area response
ND - Not Detected at the Reporting Limit	R - RPD outside accepted recovery limits
S - Spike Recovery outside recovery limits	T - TIC(Tentatively identified compound)
X - Value exceeds Maximum Contaminant Level

Pages to follow: Chain of custody 1 Extra pages included 1

Shipping container/cooler in good condition?	Yes ☑	No ☐	Not Present ☐	Temp °C 1.4
Type of thermal preservation?	None ☐	Ice ☑	Blue Ice ☐	Dry Ice ☐
Chain of custody present?	Yes ☑	No ☐		
Chain of custody signed when relinquished and received?	Yes ☑	No ☐		
Chain of custody agrees with sample labels?	Yes ☑	No ☐		
Samples in proper container/bottle?	Yes ☑	No ☐		
Sample containers intact?	Yes ☑	No ☐		
Sufficient sample volume for indicated test?	Yes ☑	No ☐		
All samples received within holding time?	Yes ☑	No ☐		
Reported field parameters measured:	Field ☐	Lab ☐	NA ☑	
Container/Temp Blank temperature in compliance?	Yes ☑	No ☐		

When thermal preservation is required, samples are compliant with a temperature between 0.1°C - 6.0°C, or when samples are received on ice the same day as collected.

Water – at least one vial per sample has zero headspace?	Yes ☐	No ☐	No VOA vials ☑
Water - TOX containers have zero headspace?	Yes ☐	No ☐	No TOX containers ☑
Water - pH acceptable upon receipt?	Yes ☑	No ☐	NA ☐
NPDES/CWA TCN interferences checked/treated in the field?	Yes ☐	No ☐	NA ☑

Any No responses must be detailed below or on the COC.

RE: GLP8006\7 **WorkOrder:** 21030724

Dear Allison Kreinberg:

TEKLAB, INC received 9 samples on 3/10/2021 2:55:00 PM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Aaron Renner
Project Manager

Client Project: GLP8006\7 **Report Date:** 07-Apr-21

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Report Date: 07-Apr-21

Qualifiers

- Unknown hydrocarbon
B - Analyte detected in associated Method Blank
C - RL shown is a Client Requested Quantitation Limit
E - Value above quantitation range
H - Holding times exceeded
I - Associated internal standard was outside method criteria
J - Analyte detected below quantitation limits
M - Manual Integration used to determine area response
ND - Not Detected at the Reporting Limit
R - RPD outside accepted recovery limits
S - Spike Recovery outside recovery limits
T - TIC(Tentatively identified compound)
X - Value exceeds Maximum Contaminant Level

Chip,

This is for their Hennepin site and should be logged in the the same as 21030443:

Total ICPMS: B Ca Fe Li Mg Mn Mo K Na (Arsenic on -002)
Dissolved ICPMS: Fe Mn Mo (As on -002)

Also, do Alkalinity B and Alkalinity C rather than just Total Alkalinity.

Let me know if you have any other questions.

Thanks,

Aaron Renner

Subject: RE: GLP 8006/7 Metals

Hi Aaron-

I checked with the field samplers and arsenic should be included for the surface water sample with 'W' in the sample ID. I'd like to request that we get rush results for lithium, boron, and molybdenum for these samples. I think by Monday would be sufficient. I am hoping that we will have received results for the samples submitted on 3/5 by Monday as well. Please let me know if you have any questions.

Thanks
Allison

Hi Aaron-

Yes, this is for the Hennepin project, GLP8006/8007 is actually the correct project number and they mislabeled it last week. Can you provide me with a copy of the COC and I'll identify which surface water sample gets arsenic and which should not be analyzed for arsenic?

Thanks,
Allison

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe. If you have any suspicion, please confirm with the sender verbally that this email is authentic.

Hi Allison,

We received 8 aqueous samples today for project "GLP 8006/7". The COC requests Total Metals and Dissolved Metals, but doesn't specify which particular metals. I suspect that these are for the Hennepin site, but since the project number is different than what I'm used to seeing for that site I wanted to double check with you before we proceed.

Could you provide the required list of metals when you have a chance?

Thanks,

Aaron Renner

RE: GLP8006/GLP8007 **WorkOrder:** 21031352

Dear Allison Kreinberg:

TEKLAB, INC received 8 samples on 3/19/2021 4:00:00 PM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Aaron Renner
Project Manager

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Report Date: 12-Apr-21

Qualifiers

- # - Unknown hydrocarbon
- B - Analyte detected in associated Method Blank
- C - RL shown is a Client Requested Quantitation Limit
- E - Value above quantitation range
- H - Holding times exceeded
- I - Associated internal standard was outside method criteria
- J - Analyte detected below quantitation limits
- M - Manual Integration used to determine area response
- ND - Not Detected at the Reporting Limit
- R - RPD outside accepted recovery limits
- S - Spike Recovery outside recovery limits
- T - TIC(Tentatively identified compound)
- X - Value exceeds Maximum Contaminant Level

RE: GLP8006/GLP8007 **WorkOrder:** 21032011

Dear Allison Kreinberg:

TEKLAB, INC received 9 samples on 3/31/2021 2:40:00 PM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Aaron Renner
Project Manager

Client Project: GLP8006/GLP8007 **Report Date:** 23-Apr-21

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Report Date: 23-Apr-21

Qualifiers

- # - Unknown hydrocarbon
- B - Analyte detected in associated Method Blank
- C - RL shown is a Client Requested Quantitation Limit
- E - Value above quantitation range
- H - Holding times exceeded
- I - Associated internal standard was outside method criteria
- J - Analyte detected below quantitation limits
- M - Manual Integration used to determine area response
- ND - Not Detected at the Reporting Limit
- R - RPD outside accepted recovery limits
- S - Spike Recovery outside recovery limits
- T - TIC(Tentatively identified compound)
- X - Value exceeds Maximum Contaminant Level

RE: GLP8006/GLP8007 **WorkOrder:** 21041324

Dear Allison Kreinberg:

TEKLAB, INC received 8 samples on 4/21/2021 5:47:00 PM for the analysis presented in the following report.

Samples are analyzed on an as received basis unless otherwise requested and documented. The sample results contained in this report relate only to the requested analytes of interest as directed on the chain of custody. NELAP accredited fields of testing are indicated by the letters NELAP under the Certification column. Unless otherwise documented within this report, Teklab Inc. analyzes samples utilizing the most current methods in compliance with 40CFR. All tests are performed in the Collinsville, IL laboratory unless otherwise noted in the Case Narrative.

All quality control criteria applicable to the test methods employed for this project have been satisfactorily met and are in accordance with NELAP except where noted. The following report shall not be reproduced, except in full, without the written approval of Teklab, Inc.

If you have any questions regarding these tests results, please feel free to call.

Sincerely,

Aaron Renner
Project Manager

Client Project: GLP8006/GLP8007 **Report Date:** 12-May-21

Abbr	Definition
*	Analytes on report marked with an asterisk are not NELAP accredited
CCV	Continuing calibration verification is a check of a standard to determine the state of calibration of an instrument between recalibration.
CRQL	A Client Requested Quantitation Limit is a reporting limit that varies according to customer request. The CRQL may not be less than the MDL.
DF	Dilution factor is the dilution performed during analysis only and does not take into account any dilutions made during sample preparation. The reported result is final and includes all dilution factors.
DNI	Did not ignite
DUP	Laboratory duplicate is a replicate aliquot prepared under the same laboratory conditions and independently analyzed to obtain a measure of precision.
ICV	Initial calibration verification is a check of a standard to determine the state of calibration of an instrument before sample analysis is initiated.
IDPH	IL Dept. of Public Health
LCS	Laboratory control sample is a sample matrix, free from the analytes of interest,spiked with verified known amounts of analytes and analyzed exactly like a sample to establish intra-laboratory or analyst specific precision and bias or to assess the performance of all or a portion of the measurement system.
LCSD	Laboratory control sample duplicate is a replicate laboratory control sample that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MBLK	Method blank is a sample of a matrix similar to the batch of associated sample (when available) that is free from the analytes of interest and is processed simultaneously with and under the same conditions as samples through all steps of the analytical procedures, and in which no target analytes or interferences should present at concentrations that impact the analytical results for sample analyses.
MDL	"The method detection limit is defined as the minimum measured concentration of a substance that can be reported with 99% confidence that the measured concentration is distinguishable from method blank results."
MS	Matrix spike is an aliquot of matrix fortified (spiked) with known quantities of specific analytes that is subjected to the entire analytical procedures in order to determine the effect of the matrix on an approved test method's recovery system. The acceptable recovery range is listed in the QC Package (provided upon request).
MSD	Matrix spike duplicate means a replicate matrix spike that is prepared and analyzed in order to determine the precision of the approved test method. The acceptable recovery range is listed in the QC Package (provided upon request).
MW	Molecular weight
NC	Data is not acceptable for compliance purposes
ND	Not Detected at the Reporting Limit
NELAP	NELAP Accredited
PQL	Practical quantitation limit means the lowest level that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operation conditions.
RL	The reporting limit the lowest level that the data is displayed in the final report. The reporting limit may vary according to customer request or sample dilution. The reporting limit may not be less than the MDL.
RPD	Relative percent difference is a calculated difference between two recoveries (ie. MS/MSD). The acceptable recovery limit is listed in the QC Package (provided upon request).
SPK	The spike is a known mass of target analyte added to a blank sample or sub-sample; used to determine recovery deficiency or for other quality control purposes.
Surr	Surrogates are compounds which are similar to the analytes of interest in chemical composition and behavior in the analytical process, but which are not normally found in environmental samples.
TIC	Tentatively identified compound: Analytes tentatively identified in the sample by using a library search. Only results not in the calibration standard will be reported as tentatively identified compounds. Results for tentatively identified compounds that are not present in the calibration standard, but are assigned a specific chemical name based upon the library search, are calculated using total peak areas from reconstructed ion chromatograms and a response factor of one. The nearest Internal Standard is used for the calculation. The results of any TICs must be considered estimated, and are flagged with a "T". If the estimated result is above the calibration range it is flagged "ET"
TNTC	Too numerous to count (> 200 CFU)

Client Project: GLP8006/GLP8007
Report Date: 12-May-21

Qualifiers

- # - Unknown hydrocarbon
- B - Analyte detected in associated Method Blank
- C - RL shown is a Client Requested Quantitation Limit
- E - Value above quantitation range
- H - Holding times exceeded
- I - Associated internal standard was outside method criteria
- J - Analyte detected below quantitation limits
- M - Manual Integration used to determine area response
- ND - Not Detected at the Reporting Limit
- R - RPD outside accepted recovery limits
- S - Spike Recovery outside recovery limits
- T - TIC(Tentatively identified compound)
- X - Value exceeds Maximum Contaminant Level

Matrix spike control limits for Ca are not applicable due to high sample/spike ratio.

Sample result for B exceeds 10 times the method blank contamination. Data is reportable per the TNI Standard.

Matrix spike control limits for Mg & K are not applicable due to high sample/spike ratio.

Contamination present in the CCB for Fe. Sample results below the reporting limit are reportable per the TNI Standard.

Sample result for Ca exceeds 10 times the CCB. Data is reportable per the TNI Standard.

CCV recovered outside the upper control limits for Mn. Sample results are below the reporting limit. Data is reportable per the TNI standard.

EXECUTIVE SUMMARY

This document has been prepared as an attachment to the Corrective Action Alternatives Analysis (CAAA) prepared by Gradient for Hennepin Power Plant West Ash Pond System (WAPS). The constituents of concern (COCs) addressed in this document are arsenic, boron, lithium, sulfate, and total dissolved solids (TDS), which have been identified as having exceedances[1] of the site-specific groundwater protection standards (GWPS) at the time of this analysis. Of these COCs, boron, sulfate, and arsenic were addressed in geochemical modeling efforts. Natural geochemical processes may be appropriate as a "polishing step" for residual plume management after effective source control implementation, if there are no risks to receptors and/or the contaminant plume is not expanding (United States Environmental Protection Agency [USEPA] 1999; USEPA 2015). Source control is a major component of every corrective action considered in the CAAA, and there are no risks to human health or the environment at Hennepin WAPS.

Natural groundwater polishing processes, which include both physical and chemical mechanisms, reduce the concentration of COCs in the groundwater. After source control is implemented, a geochemical trailing gradient may form in the subsurface as conditions undergo a return to background water quality which could affect chemical groundwater polishing mechanisms (Savannah River National Laboratory 2011). This report supports groundwater polishing as a component of the proposed corrective action by evaluating the contribution of chemical mechanisms to groundwater polishing under current conditions and after source control implementation. The groundwater flow and transport model estimated the time to reach the GWPS based on hydraulic properties of the aquifer. The results of this groundwater polishing evaluation contextualize these estimates by evaluating the potential for attenuation of COCs and for previously attenuated COCs to be mobilized to groundwater as groundwater quality returns to background conditions.

Groundwater polishing mechanisms were assessed using speciation and reaction geochemical models: speciation models assess the distribution of constituents between solid and aqueous phases, and reaction models evaluate how that distribution may change with changing site conditions (USEPA 2015). Inputs to the model include geochemically reactive solid mineral phases, compliance well groundwater composition, and background groundwater composition based on site-specific data. Additional modeling and analysis was completed to better understand arsenic speciation, solubility, and mechanisms of mobilization at wells with arsenic GWPS exceedances.

The results of the groundwater polishing evaluation indicate that chemical attenuation of modeled COCs (arsenic, boron, and sulfate) is feasible under current conditions through sorption to iron and aluminum oxide minerals. Though some degree of desorption is predicted with background

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or Groundwater Protection Standards as described in the proposed groundwater monitoring program which was submitted to the IEPA on October 25, 2021 as part of Dynegy Midwest Generation, LLC's operating permit application for the West Ash Pond System. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and therefore Dynegy Midwest Generation, LLC has not identified any actual exceedances.

water interaction, aqueous boron and sulfate (and therefore TDS) concentrations should decrease below the GWPS at all wells in the compliance monitoring network following source control. Remobilization of boron and sulfate is unlikely to affect the estimated time to reach the GWPS based on modeling results. Aqueous arsenic concentrations are predicted to increase at wells with current exceedances following remobilization of arsenic under future conditions. Remobilization may impact the time to reach the GWPS for arsenic. Lithium was not evaluated in the geochemical modeling because lithium concentrations continue to decline following unit closure. These results will inform corrective action groundwater monitoring and adaptive site management, critical components every corrective action considered in the CAAA.

1. INTRODUCTION

This document has been prepared as an attachment to the Corrective Action Alternatives Analysis (CAAA) prepared by Gradient for Hennepin Power Plant West Ash Pond System (WAPS). The purpose of the CAAA is to holistically evaluate potentially viable corrective actions to remediate groundwater and achieve compliance with GWPS for all monitored parameters under Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845.600. The constituents of concern (COCs) addressed in this document are arsenic, boron, lithium, sulfate, and total dissolved solids (TDS)[2], which have been identified as having exceedances of the site-specific groundwater protection standards (GWPS) at the time of this analysis. In the CAAA, all corrective actions considered consist of source control and residual plume management. Natural geochemical processes may be appropriate as a "polishing step" for residual plume management after effective source control implementation, if there are no risks to receptors and/or the contaminant plume is not expanding (United States Environmental Protection Agency [USEPA] 1999; USEPA 2015). Source control is a major component of every corrective action considered in the CAAA, and there are no risks to human health or the environment at Hennepin WAPS.[3]

Groundwater polishing processes include both physical and chemical mechanisms within the subsurface which reduce the concentration of COCs in the groundwater. Physical components of groundwater polishing, including advection, dilution, and dispersion, are assessed by groundwater flow and transport modeling (Groundwater Modeling Technical Memorandum[4]). Chemical mechanisms of groundwater polishing include sorption and mineral precipitation. After source control is implemented, a geochemical trailing gradient may form in the subsurface as conditions undergo a return to background water quality which could affect chemical groundwater polishing mechanisms (Savannah River National Laboratory [SRNL], 2011). The chemical mechanisms of groundwater polishing at Hennepin WAPS are evaluated herein using a geochemical modeling-based approach informed by site-specific data. This report uses geochemical modeling to evaluate the influence of chemical mechanisms on groundwater polishing under current conditions and future conditions. Additional modeling and analyses were conducted to further investigate arsenic distribution, solubility, and mobilization within the western portion of the WAPS.

The groundwater flow and transport model (Groundwater Modeling Technical Memorandum[5]) estimated the time for COCs to reach their respective GWPS under different potential corrective actions based on physical components of groundwater polishing and did not incorporate any potential chemical controls on parameter distribution. The geochemical modeling efforts presented herein support the assessment of groundwater polishing as a component of the proposed corrective

[2] TDS measurements represent the total mass of dissolved constituents in a sample rather than a single chemical behavior. Because sulfate is the dominant contributor to TDS, results for sulfate in this analysis also apply to TDS.
[3] The Human Health and Ecological Risk Assessment serves as Appendix A of the CAAA to which this report is attached.
[4] The Groundwater Modeling Technical Memorandum serves as Appendix B.1 of the CAAA Supporting Information Report; the Corrective Action Supporting Information Report serves as Appendix B of the CAAA to which this report is attached.
[5] Ibid.

action by evaluating the potential for chemical attenuation of COCs under current and predicted future conditions as a means of contextualizing the times estimated in the flow and transport model. This analysis also provides an initial foundation for understanding groundwater chemistry to inform adaptive site management as a key component of the Corrective Action Groundwater Monitoring Plan[6].

[6] The Corrective Action Groundwater Monitoring Plan serves as Appendix B.1 to the Construction Permit Application.

2. SITE BACKGROUND

2.1 Site Overview

A thorough overview of general site characteristics is presented in Section 1 of the CAAA to which this document is attached and summarized here. The Hennepin Power Plant is owned by Dynegy Midwest Generation, LLC and was in operation from the early 1950s to 2019. The facility is located four miles northeast of the Village of Hennepin, Illinois, along the Illinois River. The Hennepin WAPS is located west of the Hennepin Power Plant and adjacent to the Illinois River. The Hennepin Power Plant property is bordered by farm fields to the east and south, low lying floodplains to the west, and the Illinois River to the north.

The WAPS is comprised of two inactive sub-units, the Old West Ash Pond (OWAP) and the Old West Polishing Pond (OWPP). The OWAP includes a 9.3-acre Pond No.1 on the eastern end of the WAPS impoundment and a 16.4-acre Pond No. 3 in the central portion of the impoundment. Pond No. 1 accepted bottom ash and slag and Pond No. 3 accepted mixed coal ash. The 4.7-acre OWPP was used as a secondary pond and is located on the western end of the impoundment. The WAPS operated between 1952 and 1996, and closure occurred between 2019 and 2020 (Dynegy 2020a and 2020b).

A groundwater monitoring network was proposed in the Initial Operating Permit Application (Burns & McDonnell 2021) in accordance with 35 I.A.C. § 845.630 to monitor groundwater quality which passes the waste boundary as part of the Operating Permit Application to Illinois Environmental Protection Agency (IEPA) for the WAPS. The proposed groundwater monitoring network is shown in **Attachment A**. The monitoring network consists of nine compliance monitoring wells (21R, 22, 22D, 23, 27, 35, 49, 50, and 51) and two background wells (32 and 34).

The geology underlying the Site in the vicinity of the WAPS consists of three distinct hydrostratigraphic units (Natural Resource Technology, Inc. 2017):

- **Fill Unit:** The Fill Unit underlies the WAPS and was present in all Pond sub-units prior to closure. The Fill Unit consists of coal combustion residuals (CCR), primarily fly ash and smaller amounts of bottom ash and slag. In some locations within the unit, CCR was mixed with sand, silt, and clay to form constructed berms. The Fill Unit no longer underlies the western end of the WAPS, as CCR and one foot of soil beneath the CCR was removed from the OWPP during closure.
- **Uppermost Aquifer Unit (UAU):** The UAU contains clay, silt, and sand, collectively referred to as Cahokia alluvium, and outwash sand and gravel deposits of the Henry Formation. The UAU is the uppermost aquifer and primary groundwater transport pathway in the vicinity of the WAPS.
- **Bedrock Confining Unit (BCU):** The BCU is a low permeability unit comprised of Pennsylvanian age shale with interbedded limestone, sandstone, and clay.

Groundwater within the UAU and near the WAPS migrates north and west towards the Illinois River, consistent with surface topography. When the WAPS was operational, sluicing of ash created radial flow conditions that caused a portion of the groundwater beneath the WAPS to flow towards wetlands located south and west of the OWAP. Under normal post-closure conditions, groundwater beneath the WAPS flows toward the river. Groundwater typically flows laterally within the hydrostratigraphic units, with converging upward flow near and beneath the river. A map showing representative groundwater flow direction at the site is shown in **Attachment A**.

2.2 Identified Exceedances of the GWPS

The following GWPS exceedances at compliance groundwater monitoring wells likely attributable to the Hennepin WAPS were observed from 2023 Q2 through 2024 Q3 (Ramboll 2024):

- Arsenic – Observed at monitoring wells 21R and 51.
- Boron – Observed at monitoring wells 21R, 22, 23, and 35.
- Lithium – Observed at monitoring well 22.
- Sulfate – Observed at monitoring wells 23 and 35.
- TDS – Observed at monitoring well 35.

The data set for geochemical modeling was finalized after the 2024 Q3 sampling event. Groundwater at these compliance wells is representative of groundwater conditions downgradient of the unit, and samples may be referred to as downgradient groundwater.

GWPS exceedances in the WAPS network occur exclusively in the UAU. Arsenic exceedances are limited to two wells near the northwest corner of the WAPS. Arsenic concentrations at these two monitoring locations have been elevated post-closure. Boron is widely distributed throughout the WAPS network, with multiple locations containing boron exceedances. Boron is generally stable or decreasing over time, except at well 35 which may be influenced by localized post-closure flow conditions near the south boundary of the WAPS. Lithium exceedances are limited to one monitoring location which has exhibited a decreasing trend over time. Sulfate exceedances were observed at two monitoring locations (wells 23 and 35). TDS exceedances are observed at one monitoring location (well 35). Sulfate is the dominant contributor to TDS at well 35, so TDS concentrations are expected to follow sulfate trends at this location.

Modeling parameters with observed exceedances is appropriate to the scope of the CAAA. Additionally, the selected remedy will meet the performance standards of 35 I.A.C. § 845.670(d) and the Corrective Action Plan will be submitted to the Agency on or before May 8, 2025. Once implemented and completed, the selected remedy will attain the GWPSs.

2.3 Geochemical Conceptual Site Model

A Geochemical Conceptual Site Model (GCSM)[7] was developed for the Hennepin WAPS to describe the geochemical processes that contribute to mobilization and attenuation of constituents in the environment under current conditions, including evaluating whether chemical interactions of COCs with aquifer solids contribute to attenuation of aqueous concentrations at compliance monitoring wells (Geosyntec 2024). This discussion relies on lab reports and raw data previously presented in the Nature and Extent Report submitted to IEPA on May 8, 2024 (Ramboll 2024) in accordance with 35 I.A.C. § 845.650(d)(1) and provided again in full and with relevant updates presenting ongoing work as Appendix D of the CAAA to which this report is attached.

The primary source of arsenic, boron, lithium, sulfate, and TDS to UAU groundwater is expected to be WAPS CCR porewater. This finding is based on COC concentrations within the source and relationships to hydrogeological patterns at the site. Arsenic, boron, and lithium were identified in UAU solids adjacent to downgradient and background wells, which suggests that aquifer solids may provide an additional geogenic source of these COCs to the groundwater.

The pH is generally circumneutral and consistent across the site, though compliance wells along the north side of the WAPS tend to have slightly higher pH values than background wells. An oxidation-reduction (redox) gradient is observed across the WAPS monitoring network, with groundwater conditions changing from oxidizing to reducing from east to west, likely due to the observed increased presence of organic-rich silty soils in the subsurface of the western portion of the WAPS monitoring network. Reducing conditions at western monitoring wells likely enhance arsenic solubility and thus aqueous arsenic concentrations at wells 21R and 51.

Arsenic, boron, lithium, and sulfate in the groundwater may be attenuated via surface complexation reactions with metal oxides, such as iron and aluminum oxides. These relationships can be evaluated through analyses of aquifer solids samples, which were collected adjacent to various compliance and background monitoring wells. Detailed discussion of aquifer solids sampling and analytical results is provided in the GCSM. Discussion of additional solids sampling and analyses completed in 2024 is provided in an Addendum to the GCSM[8].

Iron oxides were detected in the initial aquifer solids dataset and are generally predicted to be stable across the network. Magnetite, a crystalline iron oxide, was detected during X-ray diffraction (XRD) analyses of aquifer solids samples with values ranging from 0.2 to 0.5%. An abundance of iron was also detected during total metals analysis of UAU solids, with concentrations ranging from 9,400 to 14,000 milligrams of iron per kilogram of solids (mg/kg). Total iron observations do not correlate well with magnetite concentrations (i.e., samples with higher iron concentrations do not necessarily have higher iron oxide minerals identified in XRD results). This suggests the presence of non-crystalline, amorphous iron oxides in the aquifer solids.

[7] The GCSM is a component of the Nature and Extent Report previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached.
[8] The GCSM is a component of the Nature and Extent Report previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached.

Amorphous (non-crystalline) iron oxides were confirmed in SEP results from samples collected and analyzed in 2024 which included a non-crystalline analysis component.

Clay minerals (kaolinite and chlorite) were also identified in aquifer solids datasets and may provide an additional attenuation mechanism for COCs due to their large surface area and electrostatic charge. At locations where reducing conditions are present, microbial sulfate reduction may contribute to lower sulfate concentrations in groundwater. TDS trends are generally consistent with the major ions in the WAPS groundwater system. Therefore, attenuation of major ions, particularly sulfate, is expected to contribute to a reduction in TDS in the groundwater.

Batch attenuation testing was conducted for arsenic to evaluate sorption and generate site-specific distribution coefficients between solid and aqueous phases. Testing yielded a K_d value in general agreement with academic studies, thus providing additional evidence of arsenic attenuation via sorption to solids in the UAU.

The GCSM findings suggest the potential for chemical attenuation of arsenic, boron, lithium, and sulfate based on detected abundances of iron oxide and clay minerals and groundwater redox conditions which are generally favorable for the stability of potential sorbing surfaces. These findings are supported by analytical results of supplementary sampling and analyses completed in 2024. Attenuation of major ions, such as sulfate, is expected to contribute to a reduction in TDS in the groundwater.

3. GROUNDWATER POLISHING REMEDY EVALUATION

This groundwater polishing evaluation uses geochemical modeling to evaluate chemical attenuation of COCs under current conditions and to predict changes in attenuation at exceedance locations following source control. This evaluation will therefore further assess if chemical mechanisms of groundwater polishing will contribute to the remedy achieving the GWPS in a reasonable amount of time. Speciation and reaction models are geochemical models that can be used to evaluate the potential for chemical attenuation in groundwater. Speciation models assess the distribution of constituents between solid and aqueous phases, and reaction models evaluate how that distribution may change with changing site conditions (USEPA 2015). The results of geochemical modeling provide insight into groundwater polishing mechanisms and additional context for the time estimated to reach the GWPS determined by the groundwater flow and transport model[9], which is based on hydraulic properties of the aquifer and does not take into account chemical interactions occurring within the hydrologic unit. Additional sampling and analyses were completed to strengthen the conceptual understanding of arsenic speciation and solubility at these two locations. Detailed discussion of additional sample collection, analyses, and results are provided in the GCSM Addendum.

3.1 Methods

Geochemical modeling was done in PHREEQC Version 3 (USGS 2021) using a modified MINTEQ v4 thermodynamic database (as described in relevant sections below). The geochemical modeling of groundwater polishing under current conditions and conditions after source control is completed includes speciation and reaction modeling (USEPA 2015):

1. Speciation: To understand groundwater polishing mechanisms under current conditions, a solid phase representative of site conditions is equilibrated with current downgradient groundwater. The results of speciation modeling represent the association of COCs with the solid phase under current conditions through mechanisms such as sorption or precipitation.

2. Reaction: In the reaction modeling, the solid phase generated during the speciation modeling phase is reacted iteratively with background groundwater. These results represent the geochemical conditions expected after the source is controlled during which a trailing geochemical gradient may be created (SRNL 2011). The reactions with background groundwater assess the potential for a trailing geochemical gradient to drive changes in groundwater chemistry. Persistence of elevated groundwater COC concentrations over several reaction iterations suggests a trailing geochemical gradient may affect the time to reach the GWPS.

The equilibrium thermodynamic modeling approach used herein allows that the solid and aqueous phases reach equilibrium during each step. The primary goal of this model is to assess whether groundwater polishing is an appropriate remedy for the site by evaluating dominant geochemical

[9] The Groundwater Modeling Technical Memorandum serves as Appendix B.1 of the Corrective Action Supporting Information Report; the Corrective Action Supporting Information Report serves as Appendix B of the CAAA to which this report is attached.

reactions that may occur at time scales relevant to groundwater flow, including adsorption and certain mineral dissolution/precipitation (i.e., iron and aluminum (hydr)oxides, carbonates, and some sulfates) as identified in the GCSM[10]. The model therefore includes those parameters that are expected to contribute to those reactions (as discussed below) and does not include every constituent of the solid phase and groundwater in order to capture "the salient aspects of the system's behavior without introducing unnecessary complexity" (USEPA 2015). This model is therefore a semi-quantitative estimation of chemical behavior in the subsurface rather than a prediction of groundwater quality, consistent with USEPA guidance that geochemical modeling "is often most helpful for identifying relative changes in contaminant speciation and distribution" (USEPA 2015).

3.1.1 Model Set-Up

Inputs to the model include solid phase composition, downgradient groundwater composition for wells 21R, 22, 23, 35, and 51, representative background groundwater composition, and representative Illinois River composition for select model runs. The PHREEQC input files and modified MINTEQ v4 database are provided in **Attachment B**. The data included for model parameterization is summarized in **Table 1** and discussed in greater detail in **Attachment C**. Most data used in the model and discussed below are provided in the Nature and Extent Report[11], including additional solids data collected in 2024 (iron and aluminum SEP results).

3.1.2 Solid Phase Inputs

Iron hydroxide (ferrihydrite, [$Fe(OH)_3$]) and aluminum hydroxide (gibbsite [$Al(OH)_3$]) are wide-spread in the environment and known to act as sorbing phases for many groundwater constituents, including arsenic, boron, and sulfate (Dzombak and Morel 1990; Karamalidis and Dzombak 2010). SEP analyses for iron and aluminum from October 2024 sampling were used to populate the ferrihydrite and gibbsite component of the geochemical models, as described in greater detail in **Attachment C**.

Metal oxide concentrations representing the 25th percentile, median, and 75th percentile of the observed data were used to test the sensitivity of the model to the amount of sorbing phase present. Both ferrihydrite and gibbsite were allowed to dissolve or precipitate in the reaction phase of the model.

Calcite and dolomite were included as mineral phases in the model because carbonate mineral formation and dissolution are often major controls on groundwater pH (Stumm and Morgan 1996; Stackelberg et al. 2020). Calcite and dolomite are present in site aquifer solids, and model input concentration were based on site-specific XRD results. Both calcite and dolomite were allowed to dissolve or precipitate in the reaction phase of the model.

---

[10] The GCSM is a component of the Nature and Extent Report previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached.

[11] The Nature and Extent Report was previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached. The Nature and Extent report contains laboratory reports and tabulated results from solid phase analysis and tabulated results from groundwater analyses. Laboratory reports for groundwater data are provided quarterly to IEPA and posted to the facility's operating record in accordance with 35 I.A.C. § 845.800(d)(15).

Barite ($BaSO_4$) and gypsum ($CaSO_4$) are minerals that contain sulfate and have the potential to form under ambient environmental conditions in a timeframe consistent with the remedial effort. Therefore, these minerals may affect sulfate attenuation. Neither mineral phase was observed in mineralogical results for WAPS samples; therefore, both were made available to precipitate from the aqueous solution but did not have initial concentrations provided.

3.1.3 Aqueous Inputs

In addition to arsenic, boron, and sulfate, the following parameters are included to capture the expected attenuation and mobilization mechanisms (see Section 2.3):

- Temperature, pH and pe[12]
- Major ions: Carbonate and bicarbonate alkalinity, chloride, fluoride, calcium, magnesium, potassium, and sodium
- Oxyanions: Silicon and phosphate
- Redox-active metals: Aluminum, iron, and manganese.
- Remaining constituents regulated under 35 I.A.C. § 845.600[13]

This full suite of geochemical parameters for this model was measured in Quarter 2 and Quarter 3, 2023. The medians of these results were used in the model to represent average groundwater interacting with the solid phase (details provided in **Attachment C**). For downgradient wells with GWPS exceedances, the median for each parameter was calculated for each location individually.

The WAPS exhibits variable redox conditions and groundwater flow patterns across the site. Upgradient wells on the east side of the WAPS are not expected to be representative of background conditions for compliance wells on the west side of the WAPS, and vice-versa. The presence of a silty lens on the west side of the site is believed to contribute to more reducing conditions observed towards the west side of the WAPS, as discussed in Section 2.3. Additionally, groundwater monitoring has indicated the occasional reversal of groundwater flow direction at well 22 (i.e., from the river into the groundwater) due to elevated river levels associated with flooding events. As a result, background water sources in modeling must be specified for individual wells rather than applied to all WAPS compliance wells.

Background groundwater was represented in speciation and reaction modeling efforts for compliance wells 21R and 51 using the median composition of background well 34 from 2023 Q2 and Q3 sampling events (referred to as WAPS-West). Background groundwater was represented in modeling efforts for compliance wells 22, 23, and 35 using the median composition of background well 32 from 2023 Q2 and Q3 sampling events (referred to as WAPS-East).

[12] See **Appendix C** for details.

[13] Mercury, thallium, total dissolved solids, and radium were not included in the model. Mercury reactions within the environment are highly complex and would require a separate modeling effort, and the high frequency of non-detect concentrations in the groundwater indicate it would not contribute to model outcomes. Thallium forms a non-reactive monovalent cation and is rarely detected in the groundwater and is therefore not expected to contribute to model outcomes. Total dissolved solids are not a chemical parameter, but rather the result of other chemical abundances taken together. Radium is not included in most thermodynamic databases.

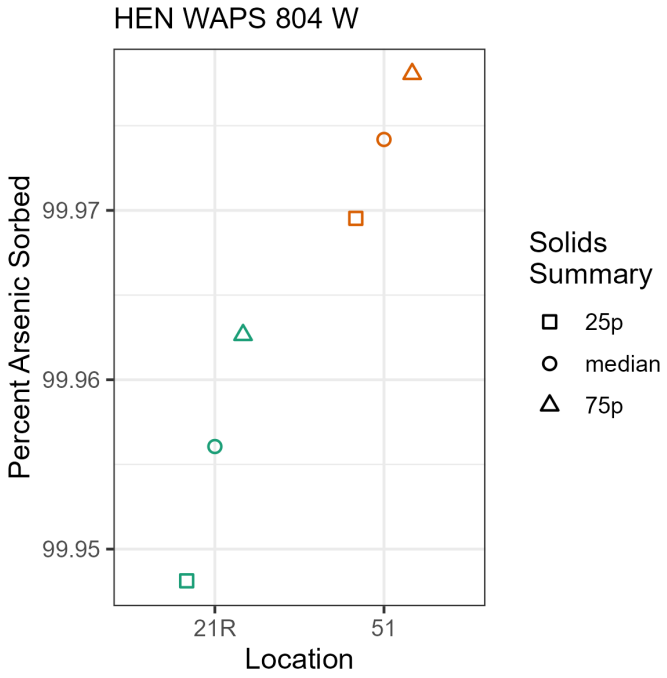
Additionally, the median composition of eight surface water samples collected from three sampling locations in the Illinois River immediately north of the WAPS was used in a separate model scenario to evaluate the Illinois River as a background water source for well 22 during flooding events (referred to as WAPS-River). These data are provided and discussed in the GCSM Addendum[14].

3.2 Results and Discussion

Geochemical modeling results are shown on **Figures 1 through 12** below. Current geochemical conditions are represented in model output figures as 'Speciation Model' and subsequent reaction calculation results are represented with 'First Reaction' and 'Second Reaction'. Full modeling outputs are provided in **Attachment D**. Results of geochemical modeling for WAPS-West model runs (wells 21R and 51) are presented in **Figures 1 to 5**. Results of modeling for WAPS-East model runs (wells 22, 23, and 35) are presented in **Figures 6 to 10**. **Figures 11 to 12** illustrate the effect of river water (WAPS-River) on geochemical reactions at well 22.

3.2.1 Model Results: WAPS West

Figure 1: Percentage of Sorbed Arsenic – West



[14]The GCSM is a component of the Nature and Extent Report previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached.

Figure 2: Modeled Arsenic Behavior – West

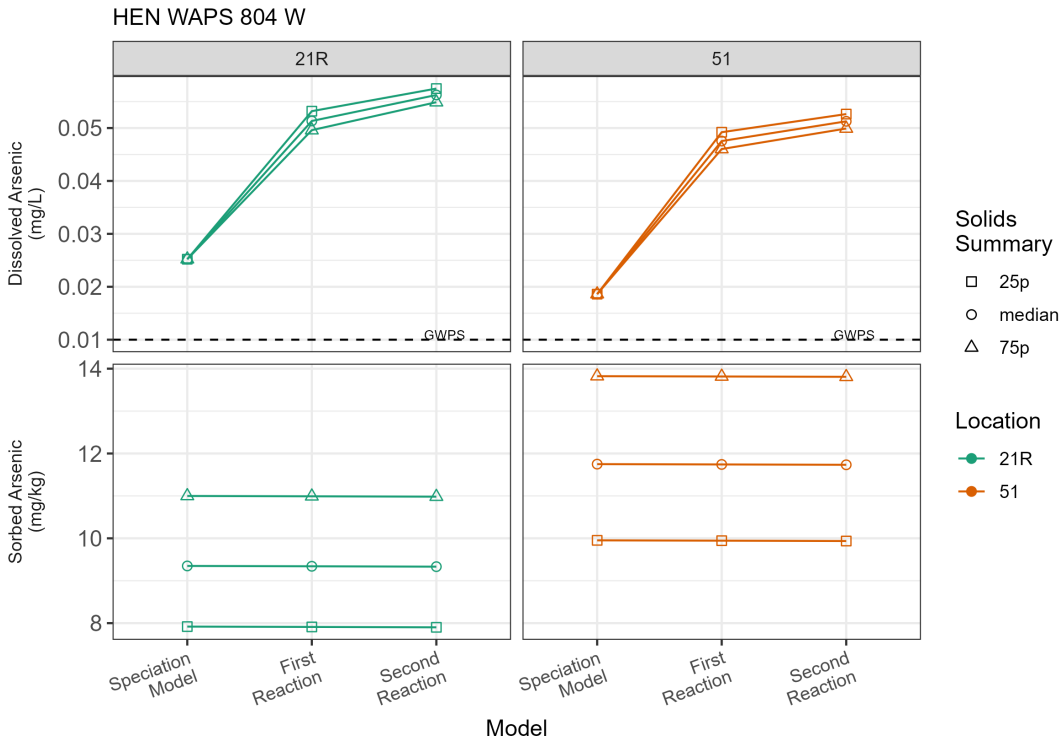


Figure 3: Percentage of Sorbed Boron - West

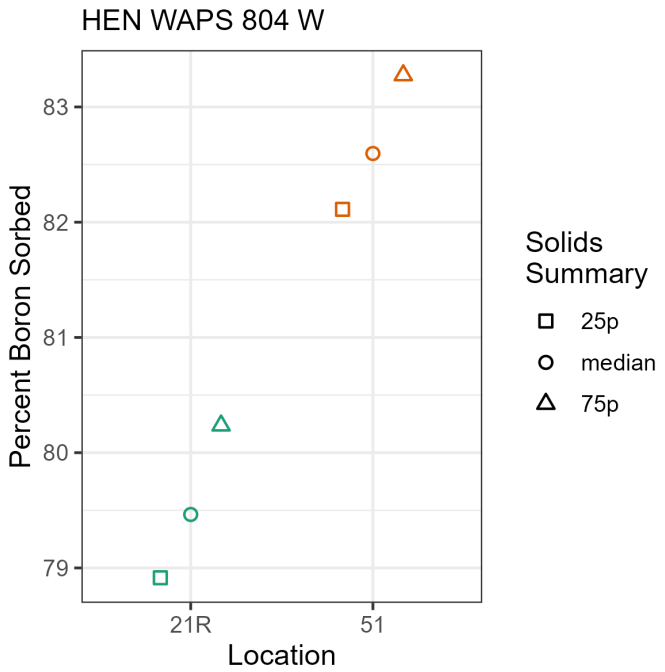

Figure 4: Modeled Boron Behavior – West

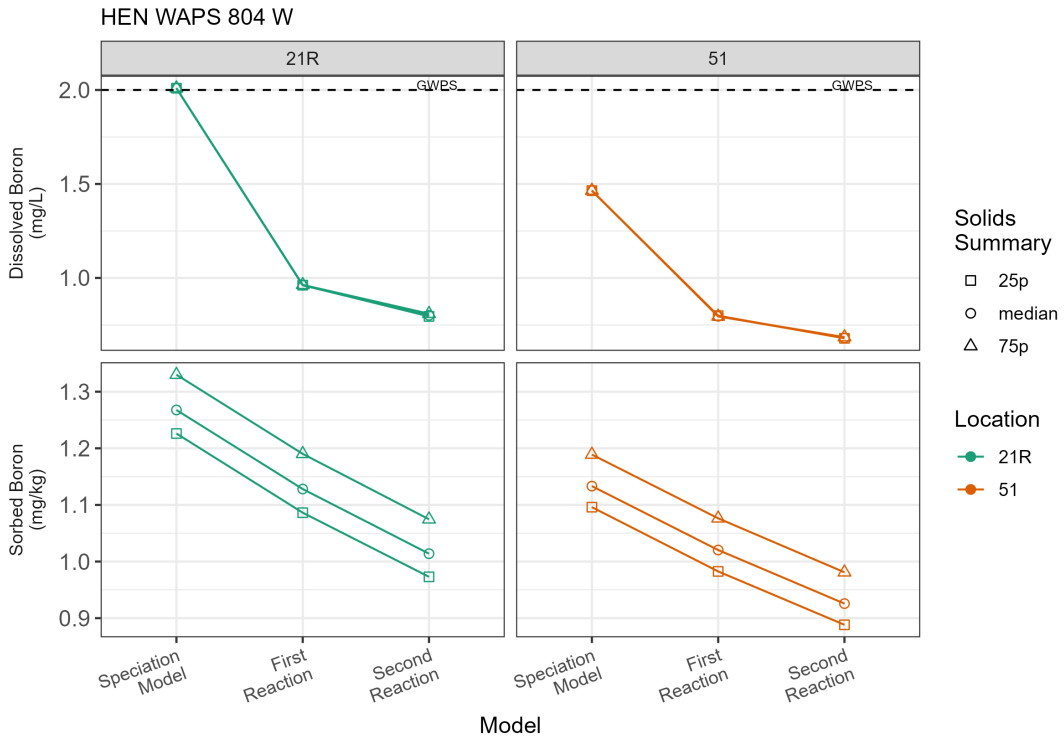

Figure 5: Modeled Sorbing Phase Behavior – West

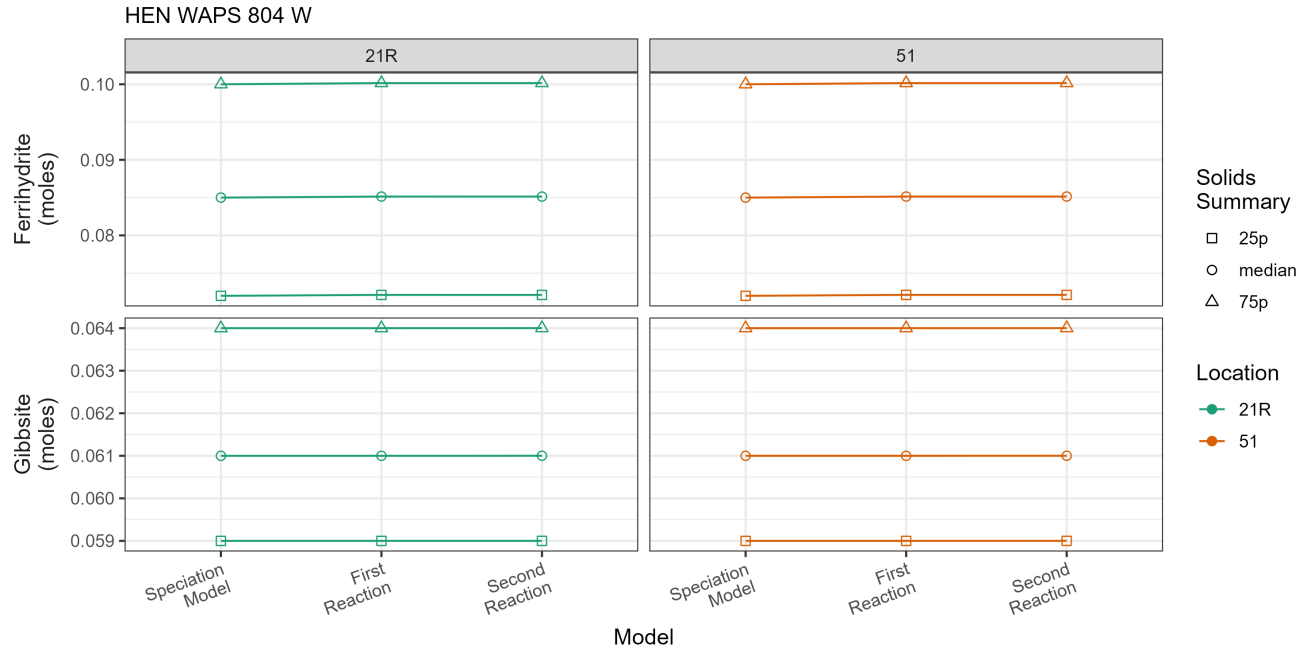

Results of speciation modeling for WAPS-West support the determination of the GCSM that chemical attenuation of arsenic and boron is likely to occur. Speciation calculations indicate that at wells with arsenic exceedances (21R and 51) greater than 99% of the arsenic present at (modeled) compliance wells is sorbed to mineral surfaces (**Figure 1**). Sensitivity assessments demonstrate that the sorbing mineral mass inputs have a minor impact on arsenic sorption, with the 25th and 75th percentile values for mineral mass accounting for differences of less than 1% of aqueous arsenic sorbed under current conditions. These results suggest that arsenic sorption to iron and aluminum hydroxide minerals should occur under current geochemical conditions.

Speciation calculations for boron indicate that at well 21R (the only well with boron exceedances on the western side of the WAPS), between 79 and 80% of boron present in groundwater will sorb to mineral surfaces (**Figure 3**). Sensitivity assessments demonstrate that the mineral mass inputs have a minor impact on boron sorption at well 21R, with the 25th and 75th percentile values for mineral mass accounting for approximately 1% of variability in aqueous boron sorbed under current conditions.

Reaction modeling results of conditions under future conditions for WAPS-West demonstrate that aqueous arsenic and boron concentrations change with interaction with background water. Aqueous arsenic concentrations are predicted to increase at wells with current exceedances (wells 21R and 51) with each iterative reaction (**Figure 2**). The predicted mobilization of arsenic is associated with desorption of arsenic from oxides, particularly ferrihydrite (**Attachment D**). This desorption is predicted to result in aqueous arsenic concentration increases following source control activities, which may impact the observed time to reach GWPS for arsenic. Arsenic speciation, solubility, and mobilization within the western portion of the WAPS is explored in greater detail in Section 3.3 of this document.

Aqueous boron concentrations at well 21R are predicted to decrease with each iterative reaction (**Figure 4**). While some boron desorption (< 0.3 mg/kg over two iterative reactions) is predicted for well 21R, the impact of this desorption on aqueous boron concentrations is offset by the influence of background groundwater containing lower aqueous boron concentrations. Mobilization of boron at well 21R is therefore unlikely to affect the modeled time to reach the GWPS.

3.2.2 Model Results – WAPS East

Results of modeling for WAPS-East model runs (wells 22, 23, and 35 with background well 32) are presented in **Figures 6 to 10**.

Figure 6: Percentage of Sorbed Boron – East

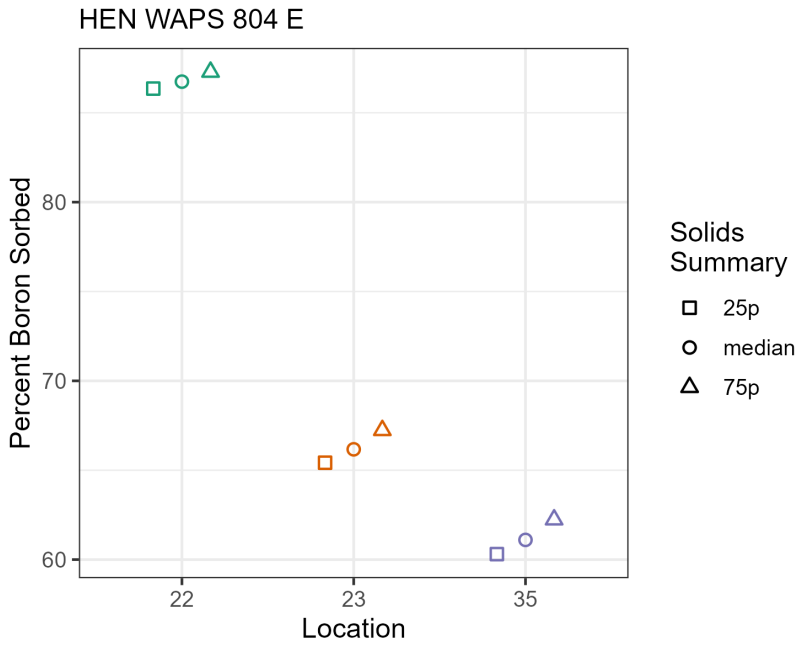

Figure 7: Modeled Boron Behavior – East

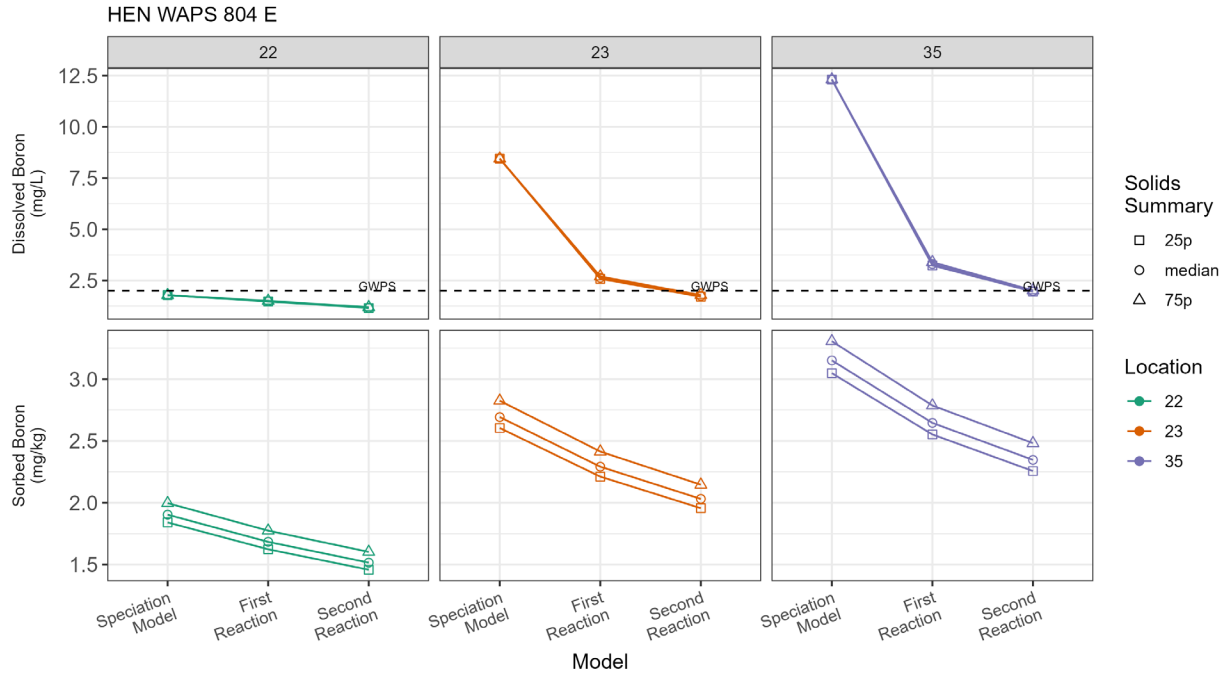

Figure 8: Percentage of Sorbed Sulfate – East

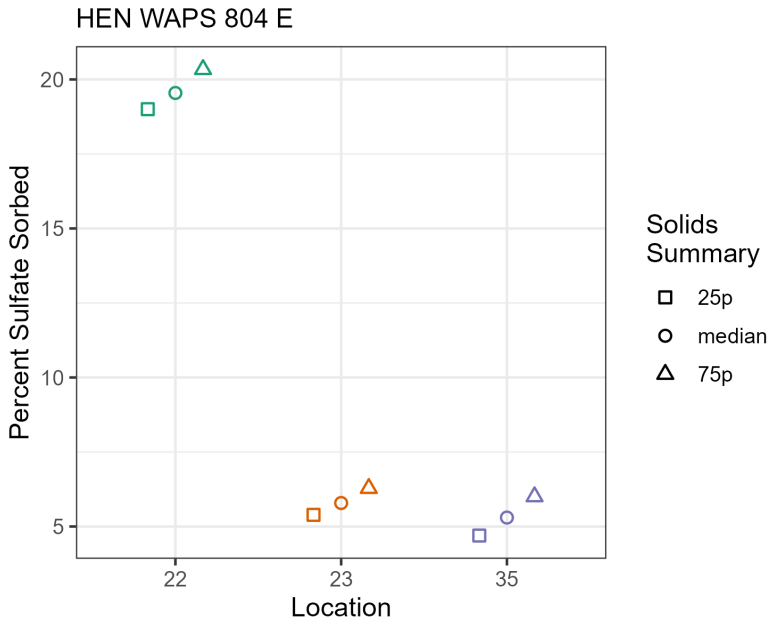

Figure 9: Modeled Sulfate Behavior – East

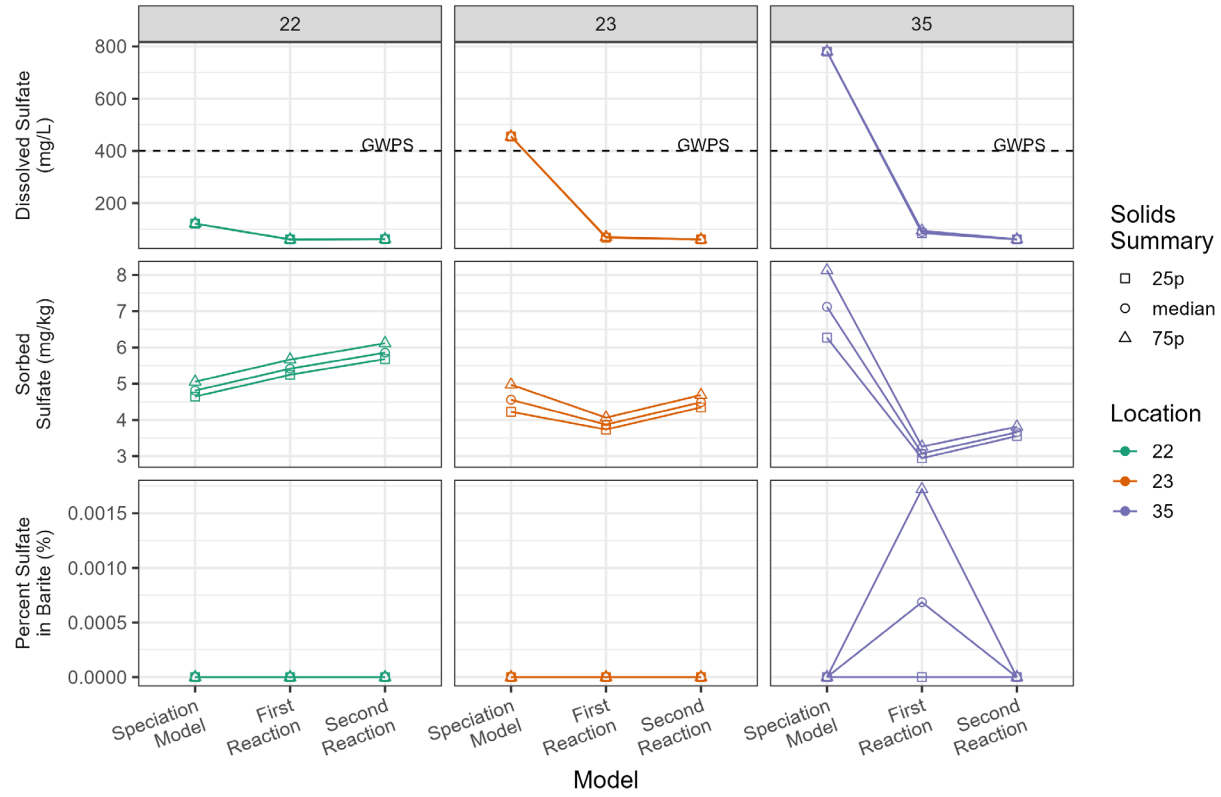

Figure 10: Modeled Sorbing Phase Behavior – East

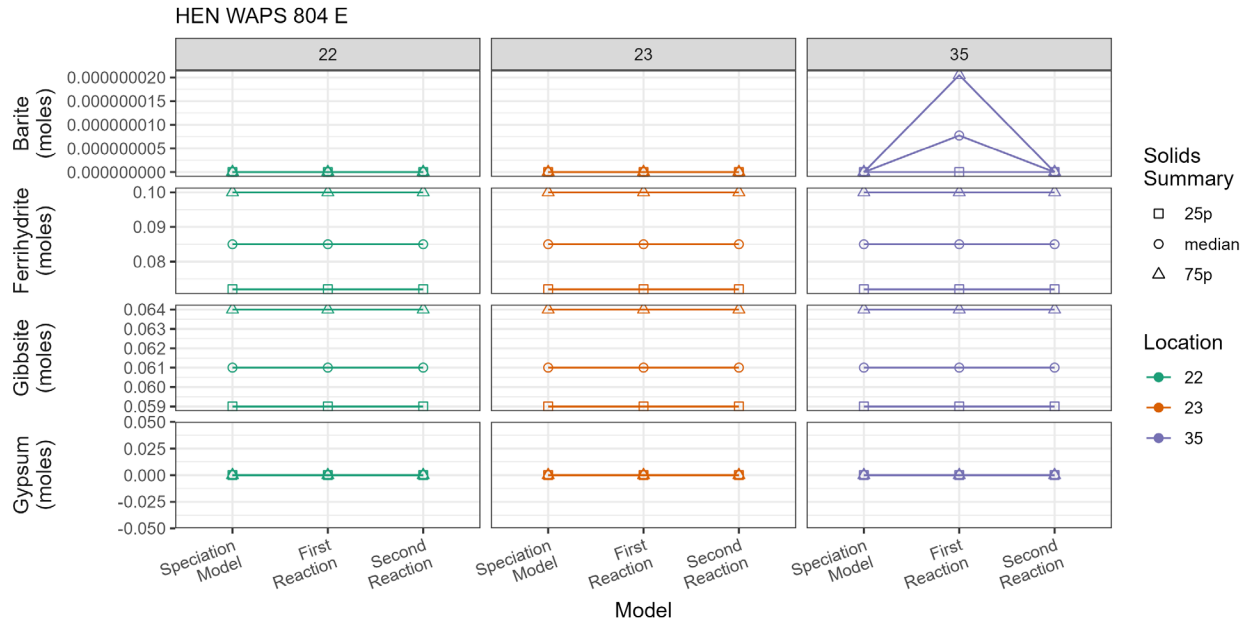

Results of speciation modeling for WAPS-East support the determination of the GCSM that chemical attenuation of boron and (to a lesser extent) sulfate is likely to occur. Wells with boron exceedances on the eastern side of the WAPS (wells 22, 23, and 35) are predicted to have between 60 and 87% of the boron present at (modeled) compliance wells is sorbed to mineral surfaces (**Figure 6**). Well 22 is predicted to experience notably greater boron sorption under current conditions than wells 23 and 35. Sensitivity assessments demonstrate that the mineral mass inputs have a minor impact on boron sorption, with the 25th and 75th percentile values for mineral mass accounting for differences of approximately 3% of aqueous boron sorbed at each well under current conditions. These results suggest that boron sorption is likely to occur under current geochemical conditions across the site, although at different magnitudes depending on well-specific geochemical conditions.

Speciation calculations for sulfate indicate that at wells with sulfate exceedances (wells 23 and 35), between 5 and 8% of sulfate present at (modeled) compliance wells is sorbed to mineral surfaces (**Figure 8**). Sensitivity assessments demonstrate that the mineral mass inputs have a minor impact on sulfate sorption, with the 25th and 75th percentile values for mineral mass accounting for differences of less than 2% of aqueous sulfate sorbed at each well under current conditions (**Figure 8**). These results suggest that some degree of sulfate sorption to iron and aluminum hydroxide minerals is likely to occur under current geochemical conditions, although less sorption is expected for aqueous sulfate relative to other COCs.

Reaction modeling results of conditions under future conditions for WAPS-East demonstrate that aqueous boron and sulfate concentrations change with interaction with background water. Aqueous boron concentrations at wells with exceedances on the eastern side of the WAPS (wells 22, 23, and 35) are predicted to decrease with each iterative reaction (**Figure 7**). Though a small amount of boron desorption (up to 0.8 mg/kg) is predicted at each well, the impact of this

desorption on aqueous boron concentrations is offset by the influence of background groundwater containing lower aqueous boron concentrations. Well 22 is predicted to achieve the boron GWPS following the first reaction and wells 23 and 35 are predicted to achieve the boron GWPS following the second reaction. These results indicate that mobilization of currently attenuated boron is unlikely to affect the modeled time to reach the GWPS.

Concentrations of aqueous sulfate at wells with exceedances (wells 23 and 35) are predicted to decrease at both wells with each iterative reaction (**Figure 9**). Some degree (up to 4.5 mg/kg) of sulfate desorption is predicted following the first reaction. However, the impact of this desorption on aqueous sulfate concentrations is offset by interactions with background groundwater containing lower aqueous sulfate concentrations. Barite precipitation is predicted under future conditions, particularly at well 35, which provides an additional attenuation mechanism for aqueous sulfate. These results indicate that mobilization of currently attenuated sulfate is unlikely to affect the modeled time to reach the GWPS.

3.2.3 Model Results – WAPS River

Figures 11 to 12 illustrate the effect of river water (WAPS-River) on geochemical reactions at well 22.

Figure 11: Modeled Boron Behavior – River

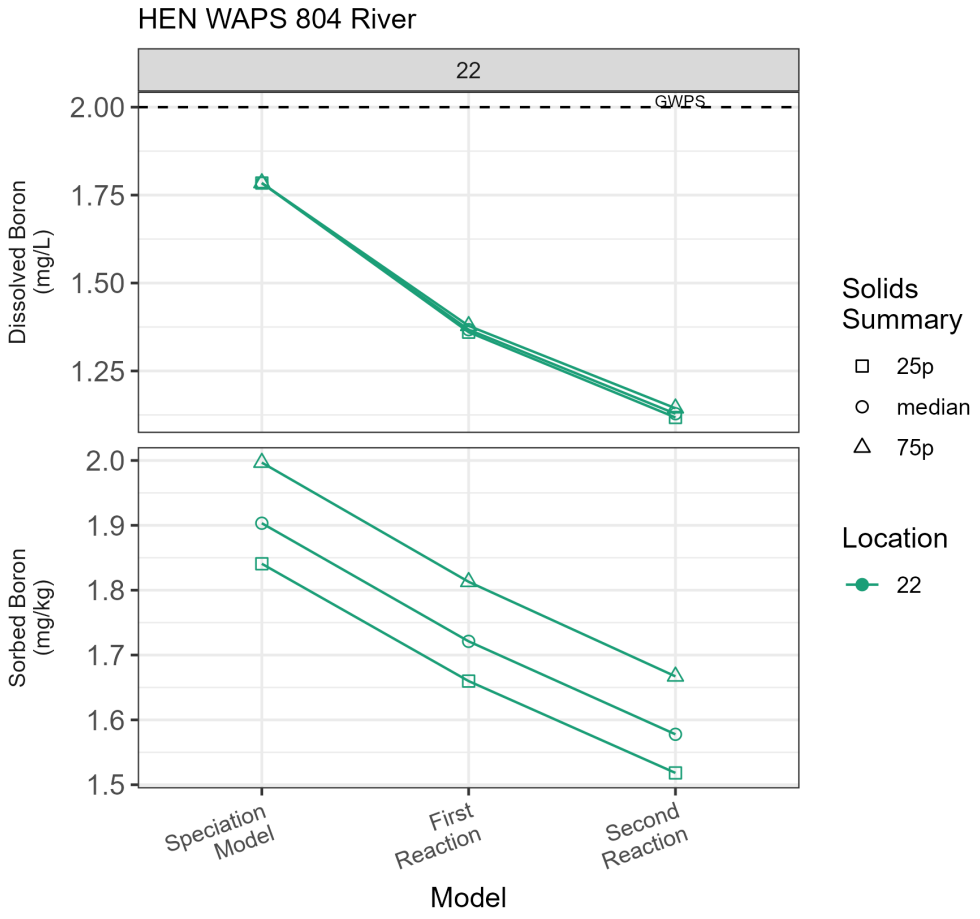

Figure 12: Modeled Sorbing Phase Behavior – River

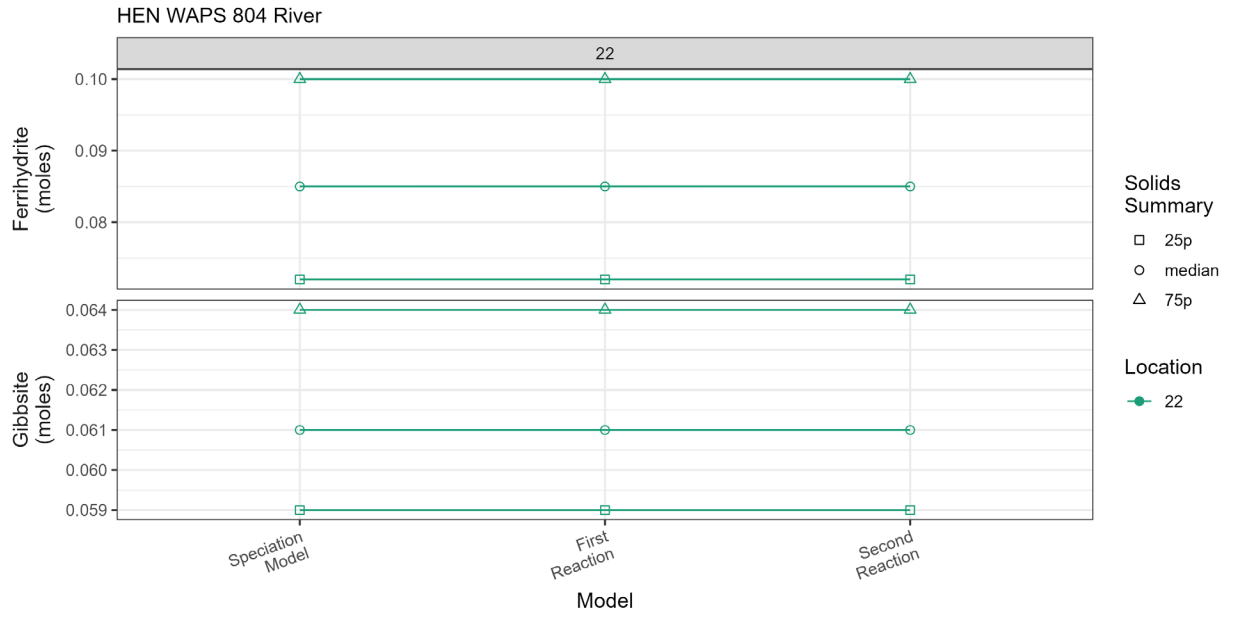


Speciation modeling results for well 22 are identical in the WAPS-River model (**Figure 11**) and the WAPS-East model (**Figure 7**), as both models incorporate the same initial aqueous and solid phase geochemical conditions at well 22.

Reaction modeling results of conditions under future conditions for WAPS-River demonstrate that aqueous boron concentrations change with interaction with background water. Reaction modeling with river water as a background source at well 22 yielded similar results as WAPS-East models with regards to boron behavior (**Figure 11**). Aqueous boron concentrations at well 22 are predicted to decrease with each iterative reaction with river water, and a small amount of boron desorption (approximately 0.3 mg/kg) is predicted.

3.2.4 Reaction Modeling Summary

Arsenic, boron, and sulfate are predicted to sorb to ferrihydrite and gibbsite. Both minerals are predicted to be stable and exhibit minor (less than 1%, **Table 2**) changes due to precipitation or dissolution reactions under future conditions (**Figures 5, 10, and 12**). Minor barite precipitation is predicted under most future conditions. The predicted stability of sorbing mineral phases and precipitation of barite under future conditions demonstrates the continued feasibility of chemical attenuation mechanisms for all COCs in the WAPS.

The primary chemical attenuation mechanism for arsenic and boron is anticipated to be sorption to iron and aluminum oxide mineral phases which are predicted to be stable under future conditions. Chemical attenuation mechanisms for sulfate are expected to include sorption to iron and aluminum oxide minerals and precipitation of barite. Results suggest that the flow and transport model conclusions are approximately correct for boron and sulfate, and that the time to reach the respective GWPS is not anticipated to be affected by desorption of COCs from the solid

phase. Chemical attenuation of sulfate is also expected to contribute to a reduction in TDS at well 35. Aqueous arsenic concentrations are predicted to be impacted by remobilization of attenuated arsenic following interaction of representative background groundwater with arsenic-bearing aquifer solids at wells 21R and 51. As such, the time to reach the GWPS for arsenic may be longer than predicted by the groundwater flow and transport model.

3.3 Supplemental Arsenic Geochemical Assessment

Remobilization of arsenic from CCR porewater and natural sources was predicted by reaction modeling and was further explored through additional solid and aqueous phase sampling and geochemical analyses as discussed in an Addendum to the GCSM[15]. The results were used as the basis of supplemental geochemical modeling with the goal of better understanding arsenic speciation, solubility, and mechanisms of mobilization at wells with arsenic GWPS exceedances.

3.3.1 Arsenic Speciation and Association

The reaction modeling results discussed in Section 3.2 predict the presence of a trailing geochemical gradient for arsenic, the result of which is a temporary increase to aqueous arsenic concentrations at wells 21R and 51 after source control is completed.

Solids analyses presented in the GCSM indicate that arsenic is present in the solid phase at background and compliance locations, indicating that a component of arsenic is geogenic. SEP analyses indicate that the majority of arsenic is associated with the oxide component. This finding was supported by XRD results which detected the iron oxide mineral magnetite, as well as other iron-bearing minerals (pyrite and ankerite).

Additional 2024 sampling and SEP analyses also indicated arsenic association with the oxide fraction, as well as notable association with the residual fraction, the sulfide fraction, and the non-crystalline fraction which is commonly associated with amorphous oxide materials; however, XRD results from 2024 sampling did not indicate the presence of iron (hydr)oxide or iron sulfide minerals.

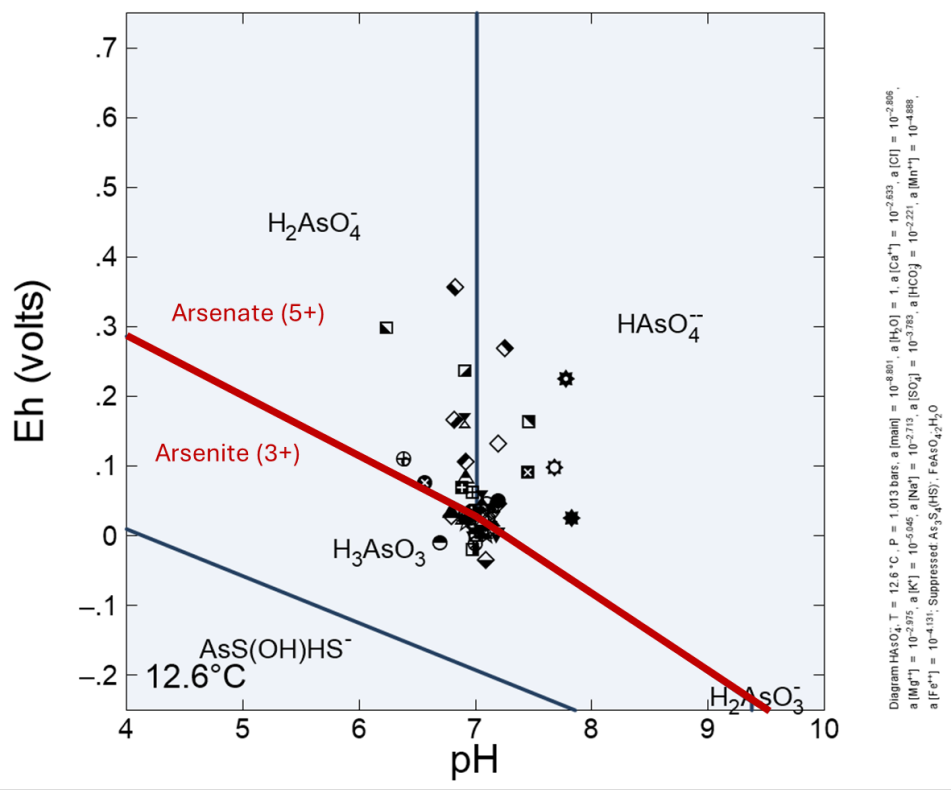
Groundwater at both wells with arsenic GWPS exceedances (21R and 51) and background well 34 was sampled in September 2024 for analysis of aqueous arsenic speciation and aqueous metals (total and dissolved). These results are provided in the GCSM Addendum. Aqueous arsenic concentrations were observed to be approximately two orders of magnitude lower at background well 34 compared to both wells with exceedances, based on total metals and arsenic speciation analyses. While aqueous arsenic at background well 34 was nearly evenly comprised of arsenite (H_3AsO_3; arsenic with a 3^+ oxidation state) and arsenate ($H_2AsO_4^{--}$; arsenic with a 5^+ oxidation state), arsenite was reported as the dominant oxidation state in wells 21R and 51. Arsenic speciation results reflect the elevated arsenic concentrations at the wells with exceedances compared to the nearest background locations and indicate that arsenite, the more mobile oxidation state of the two, dominants aqueous arsenic at these locations.

[15] The GCSM is a component of the Nature and Extent Report previously submitted to IEPA (Ramboll 2024) and is provided with relevant updates as Appendix D of the CAAA to which this report is attached.

3.3.2 Thermodynamic Evaluation

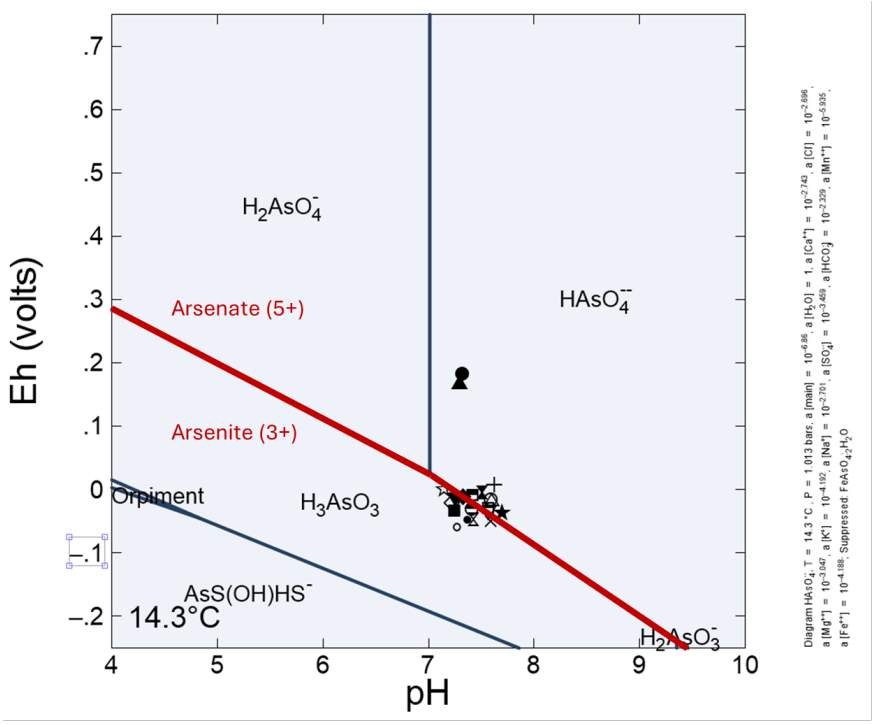
Arsenic speciation results were used to calculate electron potential (Eh) values for the arsenite/arsenate redox couple using the Nerst Equation (Panagiotaras et al. 2012). These arsenic redox couple-specific Eh values can be compared to field measured Eh values derived by converting oxidation-reduction potential (ORP) measurements (**Table 3**). Field Eh measurements account for any redox reaction occurring in the groundwater and represent an average, rather than compound-specific, redox state. Therefore, calculated Eh values were compared to Eh values measured in the field during the September sampling event provide an assessment of the discrepancy between methods, with calculated Eh values interpreted to be a more accurate representation of groundwater redox measurements for arsenic. An Eh adjustment factor of -0.08373 (V) was calculated as the difference between the mean value of calculated and measured Eh values for the September 2024 sampling event. This adjustment factor was then applied to historical Eh field measurements from wells 34, 21R, and 51. Pourbaix diagrams were then constructed using the composition of each well from the September 2024 sampling event to construct phase stability boundaries, and samples were plotted using both field-measured and adjusted Eh values (**Figures 13, 14, and 15**). Samples that plot above the red line indicate thermodynamic stability of arsenate aqueous species, whereas samples that plot below the red line indicate thermodynamic stability of arsenite aqueous species.

Figure 13: Well 34 Arsenic Pourbaix Diagram – Calculated Eh Values



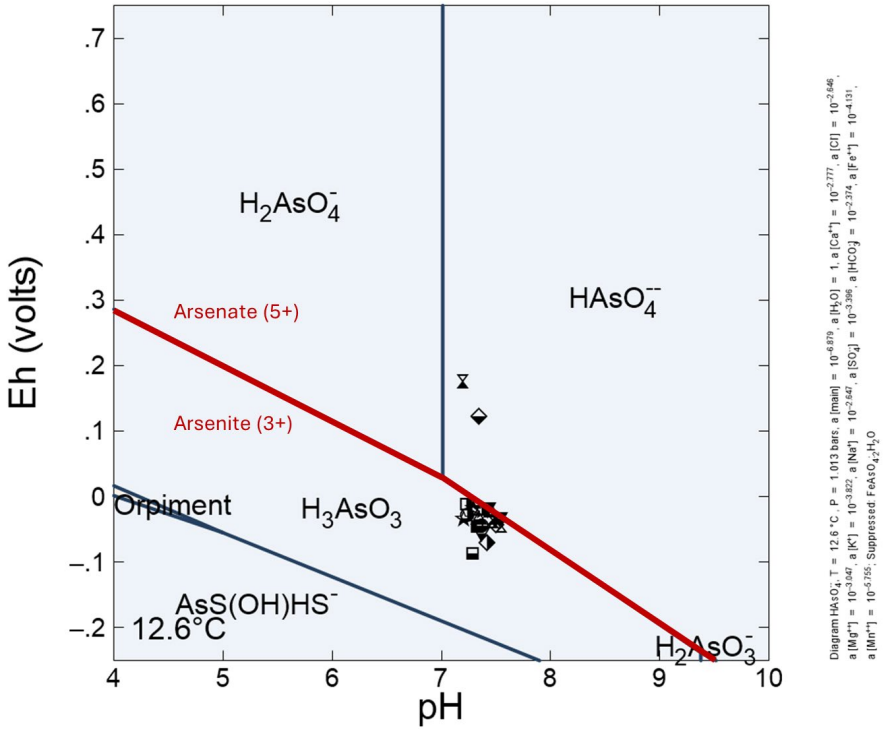
Note: Samples collected between 9/25/1996 and 10/08/2024 are displayed on the diagram

Figure 14: Well 21R Arsenic Pourbaix Diagram – Calculated Eh Values



Note: Samples collected from 03/11/2020 through 10/08/2024 are displayed on the diagram

Figure 15: Well 51 Arsenic Pourbaix Diagram – Calculated Eh Values



The arsenic speciation results and associated Pourbaix diagram findings contrast with the existing GCSM for arsenic at 21R and 51, which posited that arsenate species may be more prevalent at these locations based on data available at the time the CGSM was prepared. Recently collected data indicate that the consistently reducing conditions at these wells are actually associated with arsenic speciation favoring more mobile species (i.e., arsenite).

Arsenic speciation analyses and thermodynamic evaluations indicate that arsenite species dominate groundwater at locations with arsenic GWPS exceedances, a trait which is likely exclusive to the highly reducing, organic-rich lithology underlying the western portion of the WAPS. The current predominance of arsenite species at these locations is linked to elevated aqueous arsenic concentrations following source control, suggesting that the dominant arsenite will more readily desorb from aquifer solids with migration of background groundwater.

3.3.3 Reaction Pathway Modeling

Supplemental reaction pathway modeling was completed for well 21R to investigate the impact of dynamic geochemical conditions potentially associated with closure activities on arsenic mobility at this location. Similar to the geochemical reaction modeling described in Section 3.2, reaction pathway modeling predicts how aqueous and solid arsenic concentrations will change following source control during interaction with background water. However, reaction pathway modeling adjusts single geochemical parameters (i.e., pH and Eh) to understand their potential impacts on sorption and aqueous concentrations in isolation from the effect of desorption due to re-equilibration with a lower concentration solution. Reaction pathway modeling was only completed for well 21R as it was the only location with contemporaneous arsenic speciation and aquifer solids data collected.

Geochemist's Workbench (GWB) software package was used for reaction pathway modeling. The MINTEQ v4 database[16] was used in model calculations. Sorption to iron oxides was incorporated into the model calculations using the Dzombak and Morel (1990) two-layer surface complexation model, which is provided in GWB for the MINTEQ database as sorption dataset FeOH_minteq.sdat. Sorption sites to iron oxide materials are defined in this sorption dataset for the mineral ferrihydrite. A porosity value of 22% was used for the UAU (Natural Resource Technology, Inc., 2017).

Solids sampling adjacent to well 21R produced an SEP dataset containing results for fractions associated with oxides and non-crystalline components, which are typically representative of amorphous oxide components. These components were incorporated into the reaction pathway model to reflect the impact of arsenic sorption to well-specific aquifer solids within the model.

The initial aqueous component of the geochemical model was populated using the groundwater composition of the sample collected at well 21R in September 2024 (the nearest sampling event to the collection of aquifer solids near 21R). The model was run twice utilizing varying geochemical conditions to evaluate separately the impact of pH and redox variability on arsenic sorption and

[16]The standard MINTEQ v4 database contains identical thermodynamic data for arsenic species as the modified MINTEQ v4 database used in speciation and reaction modeling efforts. Usage of the modified database was therefore not required to maintain thermodynamic database consistence between modeling efforts.

mobility; initially fixing the pH value and setting Eh values to vary along a sliding scale towards conditions more similar to background, and secondly fixing Eh and setting pH values to vary along a sliding scale towards conditions more similar to background. Fixed pH and Eh values for the aqueous component within the model were set at values measured from well 21R during the September 2024 sampling event (pH value of 7.4 standard units [SU]; Eh value of 0.0256 mV). pH values were set to slide from 8.0 to 6.0 SU, a value inclusive of both the pH value measured at background well 34 during the September 2024 sampling event (6.8 SU) and typical range of pH values measured at well 21R. Eh values were set to slide from 0.02 to 0.20 V, a value inclusive of the less reducing groundwater conditions at well 34 (the September 2024 sampling event Eh reported value was 0.0672 V; previously observed Eh values varied from 0.0517 V to 0.443 V, with an average of 0.1630 V). Solid-phase iron reactants incorporated for sorption assessment were defined based on SEP results for iron oxides and non-crystalline materials (analytical data provided in the GCSM Addendum). Ferrihydrite was included at a mass of 4,400 micrograms per gram (µg/g), calculated by averaging the sum of iron associated with the iron oxide and iron non-crystalline material fractions for SEP samples from both well 21R solid sample intervals.

The geochemical models were used to calculate the anticipated individual effects of pH and redox variability on aqueous arsenic concentrations. Aqueous arsenic concentrations as a function of pH are shown on **Figure 16**, and concentrations as a function of Eh are shown on **Figure 17**.

Figure 16: 21R Aqueous Arsenic Concentrations as a Function of pH Variability

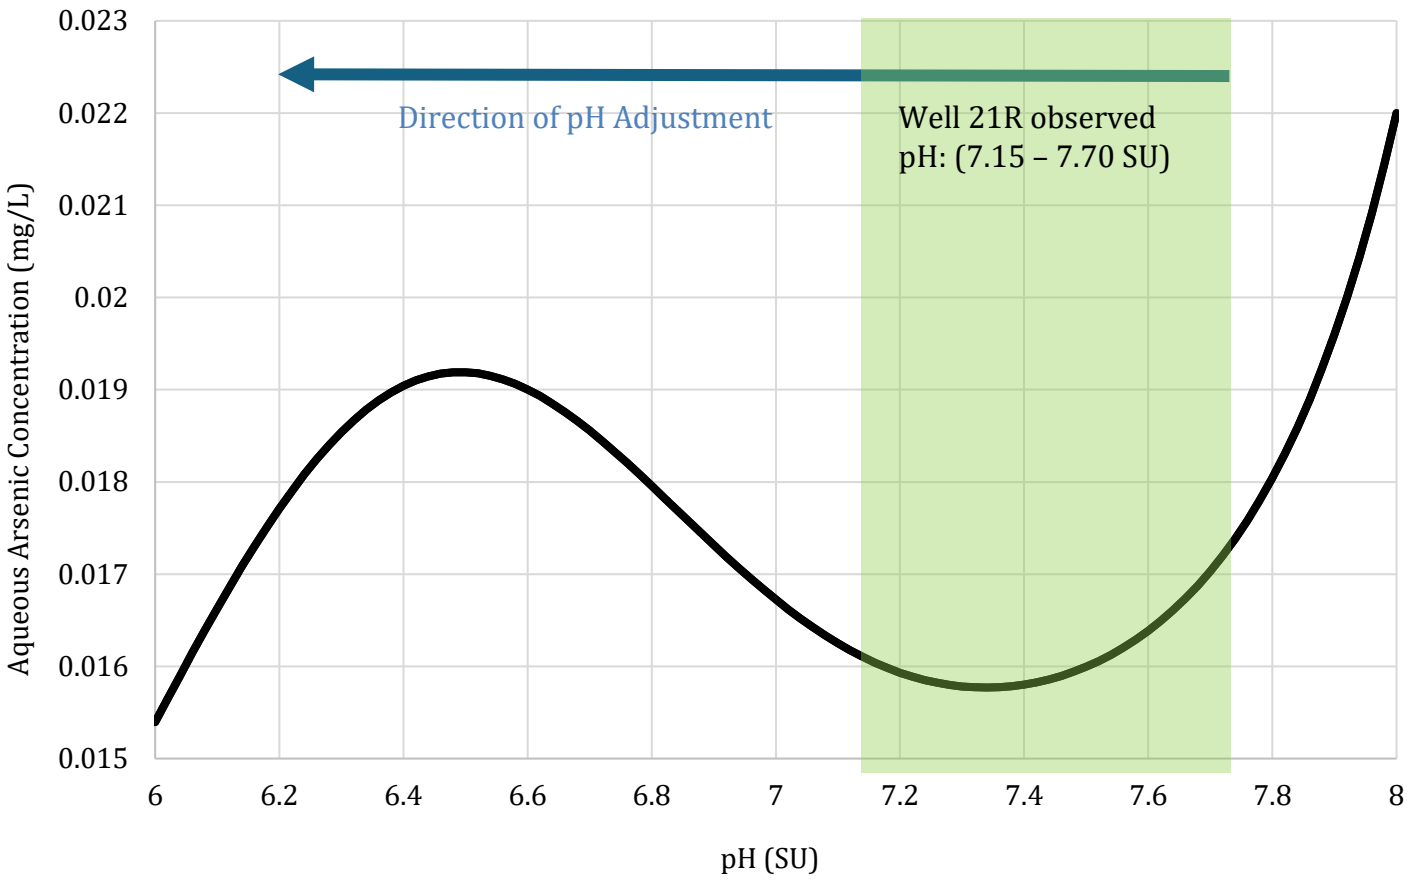


Figure 17: 21R Aqueous Arsenic Concentrations as a Function of Eh Variability

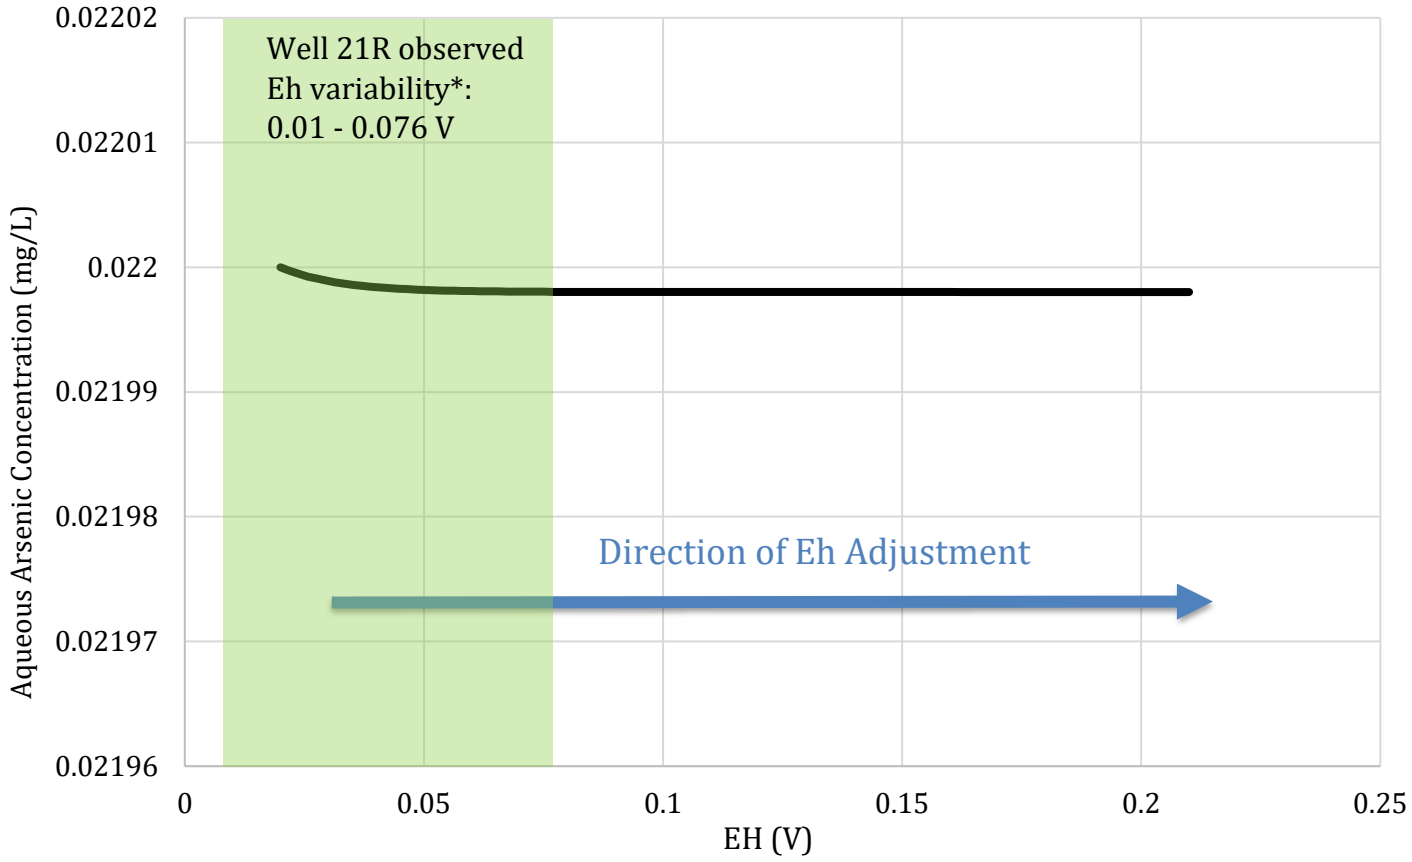

*: 21R Eh measurement variability excludes two outlier measurements of 0.252 and 0.237 V measured on 6/7/2022 and 9/13/2022 respectively

The results of the reaction pathway modeling presented in **Figures 16 and 17** indicate that while fluctuations in pH (and to a notably lesser extent, redox conditions) have a degree of influence on aqueous arsenic concentrations, the predicted aqueous arsenic increases from reaction modeling presented in Section 3.2 are unable to be achieved without interaction with low arsenic-concentration water. Reaction pathway modeling results predict that aqueous arsenic concentrations should vary from a minimum of 0.0158 mg/L (at pH 7.32 SU) to a maximum of 0.0170 mg/L (at pH 7.7 SU) within the pH range observed at well 21R to date; however, further decreases in pH values associated with background conditions are expected to influence arsenic concentrations, potentially increasing aqueous concentrations to a predicted maximum of 0.0192 mg/L at pH 6.5 (**Figure 16**). This maximum predicted value is still well below the predicted aqueous arsenic concentrations from reaction modeling presented in Section 3.2 (maximum aqueous concentrations of approximately 0.0600 mg/L, **Figure 2**).

In comparison, redox conditions (represented by Eh in the modeling effort) have less influence on aqueous arsenic concentrations, with aqueous arsenic concentrations predicted to vary negligibly as a function of Eh changes (**Figure 17**).

Combined, Section 3.2 and Section 3.3 modeling results suggest that previously modeled aqueous arsenic increases are anticipated to be caused primarily by the physical migration of lower arsenic concentration groundwater from background locations (represented by well 34 in the WAPS-West model) triggering re-equilibration leading to the subsequent desorption of arsenic from UAU solids. However, a component of aqueous arsenic mobilization is also predicted to be associated with pH changes at wells with arsenic exceedances. If groundwater flow conditions or remedial activities at the site drive substantial pH changes, additional arsenic mobilization may occur.

4. CONCLUSIONS

This report evaluated the contribution of chemical mechanisms to groundwater polishing using geochemical modeling. The results of the groundwater polishing evaluation also contextualize estimates of the modeled time to reach the GWPS by evaluating potential changes in COC attenuation as groundwater quality returns to background conditions.

Geochemical modeling of current WAPS conditions demonstrates chemical attenuation of arsenic, boron, and (to a lesser extent) sulfate via sorption to aquifer solids, particularly iron and aluminum oxides. Modeling of anticipated future conditions predicts some desorption of arsenic, boron, and sulfate from solids. Aqueous arsenic concentrations are predicted to increase at wells with current exceedances following remobilization of previously attenuated arsenic (whether due to the influence of the WAPS or from geogenic sources) under future conditions. Modeling predicts that iron and aluminum oxide sorbing mineral phases will remain stable in post-source control conditions, and as a result this chemical attenuation mechanism will remain viable for boron and sulfate. Barite precipitation is predicted under future conditions which will provide an additional attenuation mechanism for sulfate. It is expected that attenuation of sulfate will also contribute to a reduction in TDS, as sulfate is the primary contributor to TDS at well 35. Lithium was not addressed in the geochemical modeling, but lithium concentrations have steadily declined following initiation of closure activities.

Results of the geochemical modeling suggest that the time to reach boron and sulfate GWPS is not anticipated to be impacted by desorption from aquifer solids under future conditions. The observed time to reach the GWPS for arsenic may be longer than predicted by the groundwater flow and transport model due to remobilization of previously attenuated arsenic. Arsenic speciation and mobilization were further investigated in a supplemental assessment which included evaluation of recently collected solid and aqueous phase data as well as geochemical modeling. Results indicate that arsenic exists in the solid and aqueous phase at wells with arsenic GWPS exceedances, and the majority of aqueous arsenic is in the arsenic (III) oxidation state at these locations. Supplemental geochemical modeling determined that changes to pH (and to a lesser extent, redox) conditions at wells with exceedances will influence arsenic mobility somewhat. However, modeling results generally suggest that re-equilibration of aquifer solids containing sorbed or geogenic arsenic with background groundwater containing lower aqueous arsenic concentration is the primary driver of aqueous arsenic increases at wells with exceedances. These results will inform corrective action groundwater monitoring and adaptive site management, critical components of every corrective action considered in the CAAA.

ATTACHMENT C
Details of Geochemical Model Parameterization

Attachment C. Details of Geochemical Model Parameterization

Introduction

This appendix to the Groundwater Polishing Report for the Hennepin Power Plant West Ash Pond System (WAPS) provides detailed information regarding geochemical model parameterization. The information provided includes sources of thermodynamic data, sources of data used in model parameterization, summarized values, and calculation methods. All solid-phase data is fully documented in the Nature and Extent Report.[1] All aqueous data have been posted to the facility's operating record in accordance with Title 35 of the Illinois Administrative Code § 845.800(d)(15).

Solid Phase Inputs

The solid phase inputs to the model included iron (hydr)oxides and aluminum (hydr)oxides. These phases tend to have relatively rapid precipitation kinetics and form an outer layer on the surfaces of aquifer solids, creating surface area for sorption and attenuation of boron. Sequential extraction procedure (SEP) methods are described in the Geochemical Conceptual Site Model (GCSM)[2] and employ chemical extractants to dissolve metals from specific solid-associated phases. SEP methods use progressively stronger reagents to solubilize metals from increasingly recalcitrant phases. Although these procedures do not identify the discrete solid phases in a soil/aquifer matrix, they provide a means to evaluate the characterize the metal binding mechanisms and relative stability of metals in each phase, and to estimate the available mass of the respective attenuating phase(s) (i.e., aluminum and iron [hydr]oxide). While SEP analyses were completed on WAPS aquifer solids samples in March 2021 and were presented in the GCSM, the SEP methodology used to analyze these samples did not include extraction stages associated with non-crystalline or sulfide materials, both of which are important to solid-phase iron distribution. Therefore, this SEP data was not included in model set up.

SEP data from the October 2024 sampling event included two samples collected adjacent to monitoring location 21R from within the uppermost aquifer unit (UAU) at depths associated with the screened interval of 21R. The SEP analyses used for WAPS samples included a more reactive non-crystalline metal oxide fraction and a less reactive metal hydroxide fraction, as well as a sulfide fraction. Input concentrations for iron and aluminum (hydr)oxides were derived using SEP data from

[1] The Nature and Extent Report was previously submitted to IEPA on May 8, 2024, and provided with relevant updates as Appendix D of the CAAA to which this report is attached.
[2] Ibid.; the GCSM is an appendix of the Nature and Extent Report.

aquifer solids samples collected in October 2024 and discussed in the Addendum to the Nature and Extent Report.[3]

Sorption of inorganic constituents to iron (hydr)oxides in the MINTEQ v4 database[4] is represented by the hydrous ferric oxide (HFO) thermodynamic data set presented in Dzombak and Morel (1990). Sorption of inorganic constituents to aluminum (hydr)oxides is represented by the hydrous aluminum oxide (HAO) thermodynamic data presented in Karamalidis and Dzombak (2010), Goldberg and Glaubig (1985) (boron), and Kitadai et al. (2018) (sulfate). These sorption data are based on gibbsite, a nearly ubiquitous crystalline aluminum hydroxide mineral (Karamalidis and Dzombak 2010).

In thermodynamic modeling, the amount of sorbing phase present is typically the dominant control on the concentration of constituents sorbed. Therefore, different amounts of metal oxides were used to test the sensitivity of the model to the amount of sorbing phase present. The amount of metal oxides used were derived from the 25th percentile, mean, and 75th percentile of the SEP results for the relevant iron and aluminum phases.

The quantities of HFO and HAO in the model are represented by ferrihydrite ($Fe(OH)_3$) and gibbsite ($Al(OH)_3$), respectively. Ferrihydrite is the most similar naturally occurring iron oxide to HFO (Dzombak and Morel, 1990), and sorption data for HAO was determined using gibbsite (Karamalidis and Dzombak 2010). Metal concentrations are presented in milligrams per kilogram of dry weight (mg/kg dw), whereas ferrihydrite and gibbsite inputs to the model represent moles of solid phase associated with one liter (L) of aqueous phase. The concentrations of iron and aluminum were converted to moles of ferrihydrite and gibbsite (respectively) according to the following:

The mass in kilograms (kg) of solid in the model (i.e., per 1 L of water) was calculated by:

$$Solid\ Mass\ In\ Model\ (kg) = \frac{(1-\phi)}{\phi} \times \frac{1000\ cm^3\ water}{L\ water} \times 1\ L\ water\ \times \rho\ \times \frac{1\ kg\ solid}{1000\ g\ solid}$$

Where:

ϕ = porosity (water volume in cubic centimeters [cm^3] / total volume in cm^3)

ρ = density of the solid (grams [g]/cm^3)

Porosity and density represent the median of measurements each hydrostratigraphic unit as reported in the Hydrogeologic Characterization Report[5].

Moles of ferrihydrite and gibbsite were determined using metals concentrations as described above, the molar mass of iron or aluminum, and the mass of solid phase in the model:

[3] The Nature and Extent Report Addendum is provided in Appendix D of the CAAA to which this report is attached.

[4] The default MINTEQ v4 database for PHREEQC does not include sorption data for carbonate and silicate to HFO. Thermodynamic constants for sorption of carbonate and silicate to HFO were added from the MINTEQ database associated with the Geochemist's Workbench software program.

[5] The Hydrogeologic Characterization Report was previously submitted to IEPA as part of the Closure Permit Application and is provided as Appendix B.2 to the Construction Permit Application.

$$Moles\ of\ Metal\ Oxide = \frac{mg\ Fe\ or\ Al}{kg\ solid} \times \frac{g}{1000\ mg} \times \frac{moles\ Fe\ or\ Al}{g\ Fe\ or\ Al} \times kg\ Solid\ Mass\ in\ Model$$

The moles of ferrihydrite and gibbsite are represented by moles of Fe or Al (respectively) in a 1:1 ratio mased on the mineral formula. Ferrihydrite and gibbsite were allowed to precipitate or dissolve in the reaction phase of the model to evaluate the impact of source control on sorbing phase availability.

Calcite and dolomite were included as mineral phases in the model because carbonate mineral formation and dissolution are often major controls on groundwater pH. Calcite and dolomite are common carbonate minerals and were detected at levels of greater than 1% by weight in X-ray diffraction (XRD) analysis and are therefore considered to be present in excess within the aquifer. Therefore, the mass fractions reported in the XRD results presented in the GCSM are used as model inputs. Both calcite and dolomite were allowed to precipitate in the reaction phase of the model.

Barite and gypsum are common sulfate minerals that have the potential to form under ambient environmental conditions. Neither mineral was detected in XRD results at well locations containing exceedances of groundwater protection standards (GWPS). Therefore, barite and gypsum did not have initial concentrations in the model but were allowed to precipitate or dissolve in the reaction phase of the model.

Aqueous Inputs

In addition to the constituent of concern boron, the following parameters are included in the model and are anticipated to capture the expected attenuation and mobilization mechanisms for reasons detailed below:

- Temperature, pH and pe: pH and pe (a measure of redox potential) are major controls on chemical attenuation and mobility.
- Chloride, potassium, and sodium: Major ions in groundwater typically required for the model to reach charge balance.
- Carbonate ion, calcium, and magnesium: Major ions in groundwater that may also form common minerals, including carbonates. Carbonate mineral formation and dissolution is often a major control on groundwater pH. Bicarbonate and carbonate ions, a major component of groundwater alkalinity, may also compete with sulfate/boron for sorbing sites.
- Silicon and phosphate: Silicate and phosphate are oxyanions that compete with sulfate/boron for sorbing sites.
- Aluminum, iron, and manganese: As discussed above, iron and aluminum form reactive metal (hydr)oxide minerals which have high capacities for sorbing other ions on their surfaces. Although sorption to manganese oxides was not considered in this model, manganese behaves similarly to iron and is included for completeness.

- Remaining constituents regulated under 35 I.A.C. § 845.600[6]: Although these parameters are not subject to corrective action at the WAPS, they are included in the model for completeness.

Values for pe and carbonate ion concentrations were derived from values previously reported in the analytical data according to the following methods.

pe is a non-dimension scale of redox potential and is calculated from oxidation reduction potential (ORP). First, the field-measured ORP was converted to Eh (i.e., the redox potential normalized to the standard hydrogen electrode). The following equation provided in the Horiba water quality meter instruction manual[7] was used:

$$Eh = ORP + 206 - 0.7*(T - 25)$$

Where both Eh and ORP are in volts (V) and T is temperature in degrees Celsius. Eh is then converted to pe:

$$pe = (Eh * F) / (2.303 * R * T)$$

Where:

F = Faraday constant (96,500 Joules (J) / V-equivalent)

R = Molar gas constant (8.31 J / Kelvin (K)-mole)

T = temperature in Kelvin

Data reported for groundwater at the site include carbonate and bicarbonate alkalinity in units of mg of calcium carbonate per liter (mg $CaCO_3$/L). For use in modeling, it is convenient to convert these values to a single carbonate (CO_3^{2-}) ion concentration. Because carbonate and bicarbonate alkalinity are reported in the same units (i.e., standardized to mg $CaCO_3$) and represent different protonation states of the same inorganic carbon oxyanion, they were summed to represent total alkalinity due to carbonate. This summed alkalinity was converted to concentration of carbonate ion according to the following equation:

$$\frac{mg\ CO_3^{2-}}{L} = \frac{mg\ CaCO_3}{L} \times \frac{mole\ CaCO_3}{100.1\ mg\ CaCO_3} \times \frac{1\ mole\ CO_3^{2-}}{1\ mole\ CaCO_3} \times \frac{60\ mg\ CO_3^{2-}}{mole\ CO_3^{2-}}$$

The full suite of geochemical parameters for the modeling effort were measured in Quarter 2 and Quarter 3, 2023, for all compliance monitoring wells with exceedances of GWPS. The medians of these results were used in the model to represent average groundwater interacting with the solid phase.

As discussed in detail in the Groundwater Polishing Evaluation Report primary document, groundwater flow conditions at and near the WAPS are variable and warrant consideration of

[6] Mercury, thallium, total dissolved solids, and radium were not included in the model. Mercury reactions within the environment are highly complex and would require a separate modeling effort. Thallium forms a non-reactive monovalent cation and is rarely detected in the groundwater and is therefore not expected to contribute to model outcomes. Total dissolved solids are not a chemical parameter, but rather the result of other chemical abundances taken together. Radium is not included in most thermodynamic databases.

[7] https://static.horiba.com/fileadmin/Horiba/Products/Process_and_Environmental/Water_Pollution/Instruction_Manuals/U-50/U-50_Manual.pdf

appropriate background groundwater sources for individual compliance wells. Background groundwater was represented in modeling efforts for compliance wells 21R and 51 using the average composition of background well 34 from 2024 Q1 and Q2 sampling events (referred to as HEN – West). Background groundwater was represented in modeling efforts for compliance wells 22, 23, and 35 using the average composition of background well 32 from 2024 Q1 and Q2 sampling events (referred to as HEN – East). Additionally, the average composition of eight surface water samples collected from three sampling locations in the Illinois River immediately north of the WAPS was used in a separate model scenario to evaluate the Illinois River as a background water source for well 22 during flooding events (referred to as HEN – River).

The model was run without charge balancing and with charge balancing on chloride. The results during the reaction modeling did not substantially differ with and without charge balancing on chloride. The results presented in the Groundwater Polishing Evaluation Report therefore represent the model results using charge balancing on chloride.

PROPOSED

- CUTOFF WALL
- LIMITS OF FINAL COVER
- LOD — APPROXIMATE LIMITS OF DISTURBANCE

NOTE:

1. EXISTING CONTOURS ARE BASED ON FINAL CLOSURE DRAWINGS OF OLD WEST ASH POND AND OLD WEST POLISHING POND, COMPLETED BY CEC, OCTOBER 2020.
2. HORIZONTAL DATUM: ILLINOIS STATE PLANE (NAD83, IN US FEET).
3. VERTICAL DATUM: NORTH AMERICAN VERTICAL DATUM OF 1988 (NAVD88, IN US FEET).
4. CROSS SECTION LOCATIONS BASED ON THE SEPTEMBER 2017 GEOTECHNICAL SITE PLAN, PREPARED BY GEOSYNTEC AS PART OF THE 2017 CLOSURE AND POST-CLOSURE CARE PLAN FOR THE HEN OWAP AND OWPP.
5. WETLANDS REPRESENTED AS PER ILLINOIS NATIONAL WETLANDS INVENTORY AND ADAPTED TO REPRESENT ACTUAL SITE CONDITIONS.
6. BOLTONIA PLANTS AND AREAS BASED ON SCI'S DECURRENT FALSE ASTER SURVEY, SEPTEMBER 27, 2019.
7. 100-YEAR FLOODPLAIN REPRESENTED AS PER FEDERAL EMERGENCY MANAGEMENT AGENCY,"FLOOD INSURANCE RATE MAP, PUTNAM COUNTY, ILLINOIS AND UNINCORPORATED AREAS," NATIONAL FLOOD INSURANCE PROGRAM, JUNE 23, 2022 AND ADAPTED TO REPRESENT BASE FLOOD LEVEL EL. 461.9 FT.
8. THE CONTINUOUS CONTAINMENT SYSTEM DESIGN WILL BE FURTHER REFINED AS PART OF FINAL DESIGN ACTIVITIES THAT WILL BE INITIATED AFTER A CORRECTIVE ACTION CONSTRUCTION PERMIT HAS BEEN ISSUED FOR THE WEST ASH POND SYSTEM THESE ACTIVITIES MAY INCLUDE, BUT ARE NOT LIMITED TO, THE COLLECTION OF ADDITIONAL SITE SURVEY AND/OR SUBSURFACE INVESTIGATION DATA, MORE REFINED DESIGN EVALUATIONS, ADDITIONAL ENGINEERING ANALYSES, AND/OR PERMIT-RELATED CONSIDERATIONS. ELEMENTS OF THE CONTINUOUS CONTAINMENT SYSTEM DESIGN THAT WILL BE REFINED INCLUDE, BUT ARE NOT LIMITED TO, THE LIMITS OF DISTURBANCE, THE DIMENSIONS AND GEOMETRY OF THE WORK PAD, LIMITS OF THE FINAL COVER SYSTEM, TIE-IN DETAILS BETWEEN THE FINAL COVER SYSTEM, TIE-IN DETAILS BETWEEN THE DEEP CUTOFF WALL AND STORMWATER MANAGEMENT FEATURES, AND THE LOCATION OF THE DEEP CUTOFF WALL WITHIN THE WEST ASH POND SYSTEM PERIMETER DIKES.
9. CONSTRUCTION ENTRANCES, ACCESS ROADS, STAGING AREAS, AND OTHER LOGISTICAL ELEMENTS WILL BE DEFINED DURING FINAL DESIGN.
10. STORMWATER BEST MANAGEMENT PRACTICES (BMPS) WILL BE DEFINED DURING FINAL DESIGN IN ACCORDANCE WITH A SITE-SPECIFIC STORMWATER POLLUTION PREVENTION PLAN (SWPP) THAT WILL BE OBTAINED AS PART OF FINAL DESIGN ACTIVITIES.
11. CCR UNIT BOUNDARY REFLECTS THE FORMER COMBINED BOUNDARY OF THE OLD WEST ASH POND AND THE OLD WEST POLISHING POND, WHICH ARE TOGETHER THE WEST ASH POND SYSTEM. ALL CCR WAS REMOVED FROM THE OLD WEST POLISHING POND AS PART OF THE COMPLETED 2020 CLOSURE, THEREFORE THE UNIT BOUDNARY REFLECTS THE APPROXIMATE FORMER LIMITS OF CCR, BUT EXPANDS BEYOND THE CURRENT LIMITS OF CCR.

A FINAL COVER REPLACEMENT DETAIL

NOT TO SCALE

NOTES:

1. THE FINAL COVER REPLACEMENT GEOSYNTHETICS IS TO BE CONNECTED TO THE EXISTING FINAL COVER GEOSYNTHETICS AT THE LIMITS OF DISTURBANCE. THIS SHOULD INCLUDE THE FOLLOWING:
   a. FUSION OR EXTRUSION OF THE REPLACEMENT GEOMEMBRANE TO THE EXISTING GEOMEMBRANE
   b. ATTACHING THE REPLACEMENT GEOTEXTILE CUSHION TO THE EXISTING GEOTEXTILE CUSHION BY OVERLAPPING IT BY AT LEAST ONE FOOT AND EITHER MACHINE-SEWING OR THERMALLY BONDING THEM TO ONE ANOTHER.

2. WHERE THE EXISTING FINAL COVER SYSTEM EXTENDS BEYOND THE DEEP CUTOFF WALL, THE LIMITS OF THE FINAL COVER IS TO BE EQUAL TO THE LIMITS OF THE 2020 FINAL CLOSURE (E.G. EXISTING ANCHOR TRENCH LOCATION). WHERE THE CUTOFF WALL IS LOCATED BEYOND THE LIMITS OF THE EXISTING FINAL COVER SYSTEM (E.G., BEYOND THE LIMITS OF THE EXISTING ANCHOR TRENCH), THE REPLACEMENT FINAL COVER SYSTEM IS TO BE EXTENDED BEYOND THE LIMITS OF THE CUTOFF WALL, WITH THE REPLACEMENT ANCHOR TRENCH INSTALLED IMMEDIATELY ADJACENT TO THE EXTERIOR EDGE OF THE CUTOFF WALL.

3. THE REPLACEMENT GEOTEXTILE IS TO CONSIST OF A NONWOVEN POLYPROPYLENE MATERIAL THAT MANUFACTURED IN ACCORDANCE WITH THE LATEST VERSION OF GEOSYNTHETIC INSTITUTE GRI-GT12(A) STANDARD SPECIFICATION, AND WITH THE FOLLOWING REQUIREMENTS:
   a. MINIMUM MASS PER UNIT AREA OF 16 OZ/YD2 (PER ASTM D5261)
   b. MINIMUM GRAB STRENGTH OF 270 LB (PER ASTM D4632)
   c. MINIMUM TEAR STRENGTH OF 105 LB (PER ASTM D4533), AND
   d. MINIMUM PUNCTURE STRENGTH OF 725 LB (PER ASTM D6241).

   GEOTEXTILE SEAMS ARE TO BE OVERLAPPED BY 1 FT DURING PLACEMENT AND EITHER MACHINE SEWN OR THERMALLY BONDED TO ONE ANOTHER.

4. THE REPLACEMENT GEOMEMBRANE IS TO CONSIST OF A LINEAR, LOW-DENSITY POLYETHYLENE (LLDPE) MATERIAL, TEXTURED ON BOTH SIDES, MANUFACTURED IN ACCORDANCE WITH THE LATEST VERSION OF GEOSYNTHETIC INSTITUTE GM17 STANDARD SPECIFICATION, AND WITH THE FOLLOWING REQUIREMENTS:
   a. MINIMUM NOMINAL HEIGHT OF 40 MIL (PER ASTM D5994)
   b. MINIMUM ASPERITY HEIGHT OF 16 MIL (PER ASTM D7466)
   c. MAXIMUM DENSITY OF 0.939 G/ML (PER ASTM D792, OR ASTM D1505)
   d. MINIMUM TENSILE STRENGTH AT BREAK OF 60 LB/IN (PER ASTM D6693)
   e. MINIMUM ELONGATION AT BREAK OF 250% (PER ASTM D6693)
   f. MINIMUM TEAR RESISTANCE OF 22 LB (PER ASTM D1004), AND
   g. MINIMUM PUNCTURE RESISTANCE OF 44 LB (PER ASTM D3895)

   GEOMEMBRANE SEAMS ARE TO BE FUSION WELDED; REPAIRS AND PENETRATION FOR PIPE BOOTS ARE TO BE EXTRUSION WELDED.

5. THE REPLACEMENT TOPSOIL IS TO CONSIST OF A NATURAL SOIL MATERIAL THAT IS RELATIVELY HOMOGENOUS, FREE OF DEBRIS, FOREIGN OBJECTS, AND LARGE ROCK FRAGMENTS. THE TOPSOIL IS TO:
   a. BE CLASSIFIED AS A SC, CL, ML, OR OL (PER ASTM D2487), AND
   b. BE FERTILIZED, AS NECESSARY, BASED ON AGRONOMIC TESTING TO SUPPORT VEGETATION GROWTH AT THE SITE.

   TOPSOIL REMOVED FROM THE EXISTING FINAL COVER SYSTEM, WITHIN THE LIMITS OF DISTURBANCE, MAY BE STOCKPILED AND RE-USED AS REPLACEMENT TOPSOIL, IF APPROPRIATELY SEGREGATED.

6. THE REPLACEMENT COVER SOIL IS TO CONSIST OF A NATURAL SOIL MATERIAL THAT IS RELATIVELY HOMOGENEOUS, FREE OF DEBRIS, FOREIGN OBJECTS, AND LARGE ROCK FRAGMENTS. THE COVER SOIL IS TO:
   a. BE CLASSIFIED AS A CL, CH, SL-CH, CL-ML, SC, SM, SP, SW, OR SW-SP (PER ASTM D2487), AND
   b. HAVE A MAXIMUM PARTICLE SIZE OF 1.5 INCHES (PER ASTM D422 OR D6943), OR LARGER IF SUPPORTED BY A GEOMEMBRANE PUNCTURE ANALYSIS.

   COVER SOIL REMOVED FROM THE EXISTING FINAL COVER SYSTEM, WITHIN THE LIMITS OF DISTURBANCE, MAY BE STOCKPILED AND RE-USED WITH REPLACEMENT TOPSOIL, IF APPROPRIATELY SEGREGATED.

7. THE FINAL COVER SYSTEM WITHIN THE LIMITS OF DISTURBANCE IS TO BE RECONSTRUCTED TO THE SAME DESIGN SUBGRADES AS THE COMPLETED 2020 FINAL CLOSURE.

8. THE FINAL COVER SYSTEM WITHIN THE LIMITS OF DISTURBANCE IS TO BE RECONSTRUCTED TO THE SAME SURFACE GRADES AS THE COMPLETED 2020 FINAL CLOSURE.

9. VEGETATION IS TO BE RESTORED AFTER THE RECONSTRUCTION OF THE FINAL COVER SYSTEM.

10. CONTOURING FILL OR COMPACTED CCR IS TO CONSIST OF MATERIAL REMOVED DURING CONSTRUCTION TO CREATE THE WORKING PLATFORM. THE MATERIALS ARE TO BE REPLACED AFTER WALL CONSTRUCTION TO CREATE THE FINAL COVER SYSTEM SUBGRADES.

11. ANY STORMWATER CHUTES DISTURBED DURING CONSTRUCTION SHOULD BE RECONSTRUCTED TO THE SAME CONFIGURATION AS THE COMPLETED 2020 FINAL CLOSURE.

12. THE CONTINUOUS CONTAINMENT SYSTEM DESIGN WILL BE FURTHER REFINED AS PART OF FINAL DESIGN ACTIVITIES THAT WILL BE INITIATED AFTER A CORRECTIVE ACTION CONSTRUCTION PERMIT HAS BEEN ISSUED FOR THE WEST ASH POND SYSTEM THESE ACTIVITIES MAY INCLUDE, BUT ARE NOT LIMITED TO, THE COLLECTION OF ADDITIONAL SITE SURVEY AND/OR SUBSURFACE INVESTIGATION DATA, MORE REFINED DESIGN EVALUATIONS, ADDITIONAL ENGINEERING ANALYSES, AND/OR PERMIT-RELATED CONSIDERATIONS. ELEMENTS OF THE CONTINUOUS CONTAINMENT SYSTEM DESIGN THAT WILL BE REFINED INCLUDE, BUT ARE NOT LIMITED TO, THE LIMITS OF DISTURBANCE, THE DIMENSIONS AND GEOMETRY OF THE WORK PAD, LIMITS OF THE FINAL COVER SYSTEM, TIE-IN DETAILS BETWEEN THE FINAL COVER SYSTEM, TIE-IN DETAILS BETWEEN THE DEEP CUTOFF WALL AND STORMWATER MANAGEMENT FEATURES, AND THE LOCATION OF THE DEEP CUTOFF WALL WITHIN THE WEST ASH POND SYSTEM PERIMETER DIKES.

1 Introduction

This calculation package represents a preliminary, concept-level stability calculations performed to support the permit-level design of a continuous containment system (CCS) that will be constructed as part of groundwater corrective action for the West Ash Pond System (WAPS) at the Hennepin Power Plant (Hennepin). Specifically, the calculations are the stability of slurry trenches associated with installing the deep cutoff DCW (DCW) portion of the CCS. The DCW will be a cement-bentonite or soil-bentonite subsurface barrier that will encircle the perimeter of the WAPS, thereby acting as lateral containment for coal combustion residuals (CCR) contained within the WAPS.

The DCW was assumed to be installed with conventional crane-mounted construction equipment from the crest of the WAPS embankment, although alternative construction methods could be evaluated at a later phase of the design. For the purpose of this assessment, it was assumed that the crane would be positioned inboard of the DCW and will utilize a clamshell, slurry cutter, and/or hydromill to construct the DCW.

During DCW excavation, the DCW was assumed to be continuously full of a bentonite fluid slurry, in order to reduce the potential for the trench collapse. Depending on a construction method, the bentonite slurry would either be combined with soil and left in the subsurface (e.g., a soil-bentonite DCW), or displaced with a cement-bentonite slurry (e.g., a cement-bentonite DCW). Both construction methods, after completion, would form the low-permeability DCW.

Stability assessment of the slurry trench was performed to as a proof-of-concept assessment to evaluate the constructability of a slurry DCW for the WAPS, including evaluating not only the stability of the trench itself but the potential for construction to adversely impact the integrity of the WAPS perimeter embankments. Specifically, the stability assessment evaluated:

- The geometry of the working pad and offset of crane loading to avoid excessive trench deformations; and
- The expected factor of safety and deformations of the slurry trench DCW and perimeter dike under temporary construction surcharge and slurry trench loading.

After the DCW has hardened and the construction equipment has been removed, it was assumed that the structural integrity of the embankment will be similar to or improved relative to current conditions.

The information provided in this calculation includes:

- Information on the analysis methodology.
- A summary of material parameters utilized for the analysis.
- A discussion of analysis input parameters and boundary conditions, and
- Results of the analysis.

2 Analysis Methodology

2.1 Selected Analysis Type

PLAXIS 2D finite element software [1] was used to model the stability of the cutoff DCW trench considering the irregular geometries of the embankments or dikes, complex interactions with the surrounding soil and groundwater systems, and unspecified failure geometry of planar and/or curved (log-spiral or circular failure) sliding surfaces failures in a limit-equilibrium framework and analytical solutions [2, 3]. This 2D analysis approach allows for a representative geometry of the facility including the non-horizontal stratigraphy of the various subsurface materials, the limited width of the slurry trench parallel to the centerline of the embankment, and the crane loading during construction. More specifically, the capabilities of the software in analyzing conditions during and after DCW installation include:

- Replicating the two-dimensional field configuration of the DCW installation (i.e., position of crane, dimensions of slurry trench) in a numerical model setup.
- Considering coupled flow-deformation analyses for evaluating effective stresses under varying groundwater conditions, in addition to time-dependent behaviors such as consolidation, as well as undrained behavior of relevant soil layers for the short-term stability assessment of the cutoff DCW.
- Modeling of the interaction between the DCW and surrounding soil and the stability of the DCW under operational loads (e.g., surcharge load from crane, body forces of underlying soils and embankments or dikes). This feature provides insights into stress transfer and deformation patterns that cannot be obtained from a limit-equilibrium framework.
- Utilizing staged construction feature of the software to consider the transient simulation of excavation and slurry backfilling.
- Generating data visualization graphics showing displacement contours to support results interpretation on the stability of the DCW.
- Assessing the potential for internal deformations, such as shear strain localization and progressive failure mechanisms, which can impact the stability of the slurry trench.

2.2 Analysis Cross-Sections

Previous stability assessments were performed by Geosyntec in 2020 [4] to support the final design of the completed WAPS closure. These assessments are included as Appendix H.3 to the Construction Permit Application. This included evaluating two slope stability cross-sections, including A-A', B-B', C-C', and F-F', as shown in the geotechnical site plan figure for Hennepin (Appendix H.2 to the Construction permit Application). Ramboll reviewed the Geosyntec cross-sections and selected two, A – A' and F – F' (for preliminary analysis), based on the characteristics listed below:

- **Cross-Section A-A'**, which represents the Splitter Dike between the Old West Ash Pond (WAP) and the Old West Polishing Pond (OWPP), has a dike height of 21.5 feet and a relatively steep downstream slope of 3.4H:1V. According to the 2020 Geosyntec Calculation Report, the undrained, post-earthquake safety factor for this section is 1.31, indicating a potential risk of instability during both the construction and post-construction phases of the slurry trench.
- **Cross-Section F – F'** on the south side was selected for the slurry trench stability analysis due to the cross-section's relatively steep dike slope (2.9H:1V) downstream and a substantial thickness of silt and clay alluvium (approximately 19 feet). These characteristics make this location a critical area for assessing the effects of construction loading and long-term stability especially under transient conditions. In addition, undrained, post-earthquake analysis carried out by Geosyntec in the year 2020 calculated a factor of safety of 1.32.

Other, additional cross-sections will be evaluated as part of future final design activities that will be initiated after approval of the WAPS Correction Action Plan by the Illinois Environmental Protection Agency (IEPA).

3 Development of Material Parameters

3.1 Source Data

The slurry trench stability calculations and analyses are based on various subsurface investigations and laboratory testing programs conducted at the HEN WAPS site. These investigations are compiled in the 2020 Geosyntec final closure design calculations [4]. The information was supplemented with bedrock borings advanced by Ramboll in late 2024. A summary of each data source is provided below:

- 2020 Geosyntec Calculations [4]
    - The calculation packages included new data collected by Geosyntec and a summary of historical data collected by others.
    - Subsurface explorations including cone penetration tests, borings with standard penetration tests, permeability tests, soil corrosivity indication series tests, and installation of piezometers to monitor groundwater levels.
    - Laboratory testing including: Atterberg limits, dry unit weight, grain size analyses, moisture content, drained direct shear tests, unconfined compressive strength tests and isotopically consolidated undrained (CIU) tests.
    - Information on typical groundwater levels.
    - These calculations are provided in Appendix H.3 of the Construction Permit Application.
    - Other historical data utilized by the Geosyntec calculations but not contained within them included supplemental investigations completed by Geosyntec in 2018 and investigations

completed by AECOM in 2016. The Geosyntec report is provided in Appendix H.4 of the Construction Permit Application, while the AECOM investigations are provided as Appendix D.2 to the 2017 Hydrogeologic Site Characterization Report, which is Appendix B.2 of the Construction Permit Application.

- 2024 Ramboll Investigations
    - Three borings advanced into bedrock for the purposes of supporting permit-level design of the deep DCW.
    - A memorandum documenting these investigations, including boring logs and packer testing data, is provided as an attachment to the Nature and Extent Report for the Hennepin WAPS. The Nature and Extent Report is provided Appendix D of the Corrective Action Alternatives Analysis, which is provided as Appendix A of the Corrective Action Plan, which is in turn provided as Appendix G of the Construction Permit Application.

The 2020 Geosyntec calculations [4] included the identification and assignment of design unit weight, drained shear strength, and undrained shear strength parameters for multiple soil units[1] at cross-sections A-A' and F-F'. This information was also utilized for the DCW assessment. Specific soil units identified by Geosyntec, and described in more detail in their report [4], include:

- CCR
- Buttress
- Contouring Fill
- Sand and Gravel Dike Fill
- Silt and Clay Dike Fill
- Structural Fill with CCR
- Silt and Clay Alluvium
- Sand and Gravel Alluvium

The 2020 Geosyntec models were expanded by Ramboll to include deeper layers of weathered shale and competent shale bedrock that were identified in the 2024 Ramboll site investigation. Additional information on the weathered and competent shale is provided in the Ramboll memorandum (see the Nature and Extent Report, which is Appendix D of the Corrective Action Alternatives Analysis, which is Appendix A of the Corrective Action Plan, which is in turn Appendix G of the Construction Permit Application).

3.2 Development of Elastic Parameters

Cone penetration tests with pore pressure measurements (CPTu tests) were carried out by AECOM in 2015 as provided in Appendix H.5 of the Construction Permit Application. Ramboll utilized this data to estimate the Young's Modulus (E) of each soil unit for CPTu soundings HEN-C002 and HEN-C010. Notably, CPTu HENC010 is located on cross-section F – F' whilst HENC002 is located approximately 50 ft from cross-section A – A', as shown in the geotechnical site plan (Appendix H.2 of the Construction Permit Application).

[1] The soil units utilized by Geosyntec are geotechnical soil units and use a different naming convention that hydrogeological soil units assigned by Ramboll within the Hydrogeologic Site Characterization Report for the Hennepin WAPS (see Appendix B.2 of the Construction Permit Application). For this calculation package, the geotechnical soil unit names assigned by Geosyntec were utilized. All other documents utilize the hydrogeologic unit naming convention described in the Hydrogeologic Site Characterization Report.

Young's Modulus were estimated using the CPeT-IT software [5] based on empirical correlations on cone resistance and soil behavior type as provided by Robertson and Cabal [6]. Additionally, Poisson Ratio (v) of the soils were estimated from literature values [7, 8] and engineering judgement. Different elastic parameters were selected for each section, based on the results of this assessment. The CPT soundings and corresponding estimations of Young's modulus are provided in **Attachment A** to this memorandum.

3.3 Selection of Constitutive Models

Four constitutive soil models were used in the analysis of the slurry trench stability, as described below.

- The Hardening Soil (HS) model [1, 9] was selected to capture the stress dependent stiffness and hardening behavior of soils. These behaviors cannot be accurately represented using simpler models like Mohr-Coulomb.
    - In addition, the HS model accounts for plastic deformation from the early stages of loading by incorporating both deviatoric (shear) and volumetric (cap) hardening, allowing it to simulate soil strengthening and densification under stress. The following material units were assigned HS model to simulate the non-linear stress-strain relationship and long-term behavior including settlement due to consolidation:
        - Compacted material units such as Silt and Clay Dike fill, Sand and Gravel Dike fill, Buttress/structural fill with CCR, contouring fills and Sand and Gravel alluvium at depth.
        - HS material and strength parameters as provided by Surarak et al. [10] were assigned to simulate the stiff clay or weathered Shale.
- Cohesive soils such as Silt and Clay alluvium exhibit high compressibility, contractive behavior during undrained shearing, consolidation and time dependent settlement, making the Soft Soil model [1] a reasonable approximation of the undrained behavior of normally consolidated and lightly over-consolidated clays.
- Contractive, loose and saturated materials like CCR typically experience a rapid loss of shear strength when subjected to undrained loading [11] and the likelihood of static liquefaction. The Hardening Soil model with small-strain stiffness (HSS) can simulate the gradual softening process by incorporating both shear and volumetric plastic strains, unlike traditional models that assume instant failure [12].
    - Therefore, the CCR was assigned HSS constitutive model accounting for nonlinear stress-strain behavior and stiffness degradation at small strains. This is necessary for modeling the buildup of excess pore pressure during undrained loading and capturing the progressive failure of flow liquefaction in the case of an instability during slurry trench excavation.
- The Linear Elastic model [1] was assigned to the competent bedrock Shale unit which is relatively unweathered and competent. This is because the behavior of competent bedrock, unlike that of soils, can be approximated as linear and elastic with minimal plastic deformation under small to moderate stress levels or loading conditions.

The constitutive models required the assignment of additional engineering parameters including, but not limited to, initial void ratio, compressibility information, stiffness parameters, and shear modulus. These parameters were assigned based on a combination of laboratory compressibility data and engineering correlations, where feasible. Where the parameters were not available from the existing laboratory data, default Plaxis parameters were utilized for this concept-level stability analysis.

3.4 Selection of Shear Strength and Unit Weight Parameters

Engineering parameters including Mohr-Coulomb shear strengths (friction angles, effective cohesion, and undrained shear strength) and unit weight were developed by Geosyntec in 2020 [4] (Appendix H.3 of the Construction Permit Application) to support their limit-equilibrium shear strength characterization. The shear strength parameters were based on laboratory and in-situ testing. Ramboll utilized the same shear strength materials for each soil unit Geosyntec utilized for their calculations.

It should be noted that the Geosyntec characterization used anisotropic shear strengths (effective stress friction angle) for cohesive materials, including silt and clay alluvium and silt and clay dike fill, based on differing test results from triaxial compression and direct shear strength testing. For the silt and clay alluvium, Ramboll utilized the direct shear test results as provided in Geosyntec 2020 report, as a simplifying and conservative assumption for this concept-level analysis. Triaxial compression tests results were used for all other materials, which were not indicated to exhibit strength anisotropy.

3.5 Selection of Hydraulic Parameters

Hydraulic parameters including horizontal and vertical hydraulic conductivity were obtained from existing three-dimensional MODFLOW site groundwater modeling performed for the site by Ramboll and Natural Resources Technology, Inc. (NRT) [13, 14] and were supplemented by bedrock investigation data, including packer testing, collected by Ramboll in 2024 (see the Nature and Extent Report, which is Appendix D of the Corrective Action Alternatives Analysis, which is Appendix A of the Corrective Action Plan, which is in turn Appendix G of the Construction Permit Application).

3.6 Summary of Selected Material Parameters

The selected shear strength parameters, elastic parameters, hydraulic parameters, drainage assumptions and constitutive models utilized for the various soil and bedrock materials considered in the slurry trench stability analyses are summarized in **Table 1, 2, 3** and **4** respectively.

Table 1. Strength and Elastic Properties assigned to cross-section A – A' and F – F' for slurry trench stability analyses

Shear Strength and Unit Weight Parameters					Elastic Parameters				
					Section A-A'		Section F-F'		
Soil Material	Total Unit Weight (pcf)	Friction Angle, ϕ' (deg)	Cohesion, c' (psf)	Sources	Young's Modulus, E (ksf)	Poisson Ratio (v)	Young's Modulus, E (ksf)	Poisson Ratio (v)	Sources
CCR	99	33	0	2020 Geosyntec Calculations [4]	31	0.20	31	0.20	Correlations with CPTu data [Attachment A, [4] [15]]
Silt and Clay Dike Fill	115	30	75		1,177	0.25	2,130	0.25

Weathered Shale (Stiff Clay)	127	30	240	Literature [7, 8] [10]	198	0.20	198	0.20	Literature [10]
Competent Bedrock[1]	156	Assumed liner-elastic due to depth below grade			208,900	0.30	208,900	0.30	Literature [7, 8]

[1]Note: Required input parameters for Linear elastic material behavior are only the Young's Modulus and Poisson Ratio

[2]The 2020 Geosyntec calculations utilized a unit weight of 115 pcf above 20 ft in depth below grade and 125 pct below 20 ft in depth. This was simplified into an unsaturated unit weight of 115 pcf and a saturated unit weight of 125 pcf for this assessment.

[3]Cohesion was conservatively neglected for the Silt and Clay Alluvium material as a simplifying and conservative assumption for this concept-level analysis.

[4]A small amount of cohesion (20 psf) was assumed for the contouring fill material within the model to avoid numerical convergence issues.

Table 2. Hydraulic Properties assigned to cross-section A – A' and F – F' for slurry trench stability analysis

Material Parameters - Hydraulic			
Soil Material	Hydraulic Conductivity Ratio (k_y/k_h)	Horizontal Hydraulic Conductivity (k_h) ft/day	Sources
CCR	1	0.05	Zone 10 in MODFLOW site groundwater model [13]; Contouring Fill assumed to have the same parameters as CCR as it is primarily CCR material
Contouring Fill	1		
Sand & Gravel Dike Fill	1	0.05	Zone 10 in MODFLOW site groundwater model [13]; Assumed the same as CCR and Contouring Fill, as these materials are not included in the MODFLOW model and limited testing data is available for them
Silt and Clay Dike Fill	1	0.05	
Organic Sediments	0.1	1.4	Zone 4 in MODFLOW site groundwater model [13]
Silt and Clay Alluvium	0.1	1.5	Zone 3 in MODFLOW site groundwater model [13]
Sand and Gravel Alluvium	0.5	200	Zone 2 in MODFLOW site groundwater model [13]
Glacial Outwash	0.5	100	Zone 12 in MODFLOW site groundwater model [13]
Weathered Bedrock	0.33	0.10	Testing perfomed by Geosytnec in 2021 at the East Ash Pond [14]
Competent Bedrock	0.33	0.007	Geometric mean value from B100 & B102 in the 2024 Ramboll Packer Test Investigation *(see the Nature and Extent Report, which is Appendix D of the Corrective Action Alternatives Analysis, which is Appendix A of the Corrective Action Plan, which is in turn Appendix G of the Construction Permit Application);* k_y/k_h ratio was conservatively assumed based on Ramboll experience.

Table 3. Constitutive models and input parameters used in Plaxis 2D Numerical Simulations

Soil Material	Constitutive Model Input Parameters										
	Soil Model	Initial void ratio (e_{init})	λ[1]	k[2]	m[3]	ψ[4]	k_0nc[5]	P_{ref}[6] (psf)	R_f[7]	G_0^{ref} [8] (ksf)	$\gamma_{0.7}$[9]

Weathered Shale (Stiff Clay)	Hardening Soil (HS)	0.50	-	-	1.00	0	0.5000	2089	0.90	-	-
Competent Bedrock	Linear Elastic (LE)	0.50	-	-	-	-	-	-	-	-	-

Notes

[1] Modified compression index. Calculated from compressibility parameters provided in Geosyntec report [4], and assumed initial void ratio is 0.50 (default value from Plaxis) for all other materials.

[2] Modified swelling index. Calculated from compressibility parameters provided in Geosyntec report [4].

[3] m is power for stress-level dependency of stiffness, where 1.0 is soft soil and 0.5 is relatively stiff soil [1].

[4] Angle of dilatancy. Materials are assumed to behave in a non-associated flow rule plasticity and $\psi=0$, where $\phi \neq \psi$. Geomaterials can contract or dilate during plastic deformation.

[5] K_o value for normal consolidation, calculated as $1-\sin(\phi)$.

[6] Reference stress for stiffnesses, assumed as 100 kPa per Plaxis default settings.

[7] Failure ratio, assumed as 0.90 per Plaxis default settings.

[8] Small strain shear modulus, used for CCR only due to use of HSs model. Assigned value obtained from Sottile (2024) [15].

[9] Strain level at which the shear modulus has reduced to about 70% of the small strain shear modulus used for CCR only due to use of HSs model. Assigned value obtained from Sottile (2024) [15].

Table 4. Drainage and Elastic parameters used in Plaxis 2D Numerical Simulations

Soil Material	Drainage Assumptions		Elastic Parameters

4 Analysis Parameters and Boundary Conditions

4.1 Analysis Geometry and Groundwater Conditions

The geometry and dimensions for both cross-sections A-A' and F–F' that were utilized in the PLAXIS 2D model were developed based on limit-equilibrium SLIDE stability analyses performed by Geosyntec in 2020 [4]. Additional information about how each cross-section was developed, including the subsurface layering and source data, is provided in the 2020 Geosyntec calculations (see Appendix H.3 of the Construction Permit Application). The cross-sections were modified by Ramboll for use in this assessment by adding in weathered and competent bedrock, at elevations determined from the 2024 Ramboll field investigations (see the Nature and Extent Report, which is Appendix D of the Corrective Action Alternatives Analysis, which is Appendix A of the Corrective Action Plan, which is in turn Appendix G of the Construction Permit Application of the Corrective Action Plan). These material layers were added beneath the Sand and Gravel Alluvium soil layer assigned by Geosyntec and included a top elevation of 374.3 feet for the weathered bedrock and 364.5 feet for the competent bedrock. The bottom of the model was extended to El. 350 feet, thereby considering a total thickness of 14.5 feet of competent bedrock. The groundwater elevations utilized during the assessment were assumed to be El. 447 ft, which is the upper-normal assumption made by Geosyntec for their SLIDE stability analyses.

4.2 Conversion of 2D Limit Equilibrium Analysis to 2D Plaxis Analysis

The model geometry for Cross-sections A – A' and F – F' were scaled into PLAXIS 2D from the Geosyntec analyses. This process included assigning all ground surface elevations, subsurface layering, and other model features to the same locations and elevations used by the 2020 Geosyntec analyses.

4.3 Boundary Conditions

The boundary conditions of the slurry trench stability analyses (2D models) were assigned as follows:

- The horizontal bottom of model was assigned fixed displacement constraint where zero horizontal and vertical movements in x, and y directions were applied, thereby representing no movements in the deep competent shale bedrock
- The left and right vertical sides of the model were assigned as “rollers” where the model can move in y directions respectively, thereby allowing for settlement of the model.

Figures 1 and **2** illustrate the boundary conditions and model setup, for cross-sections A-A' and F-F', respectively.

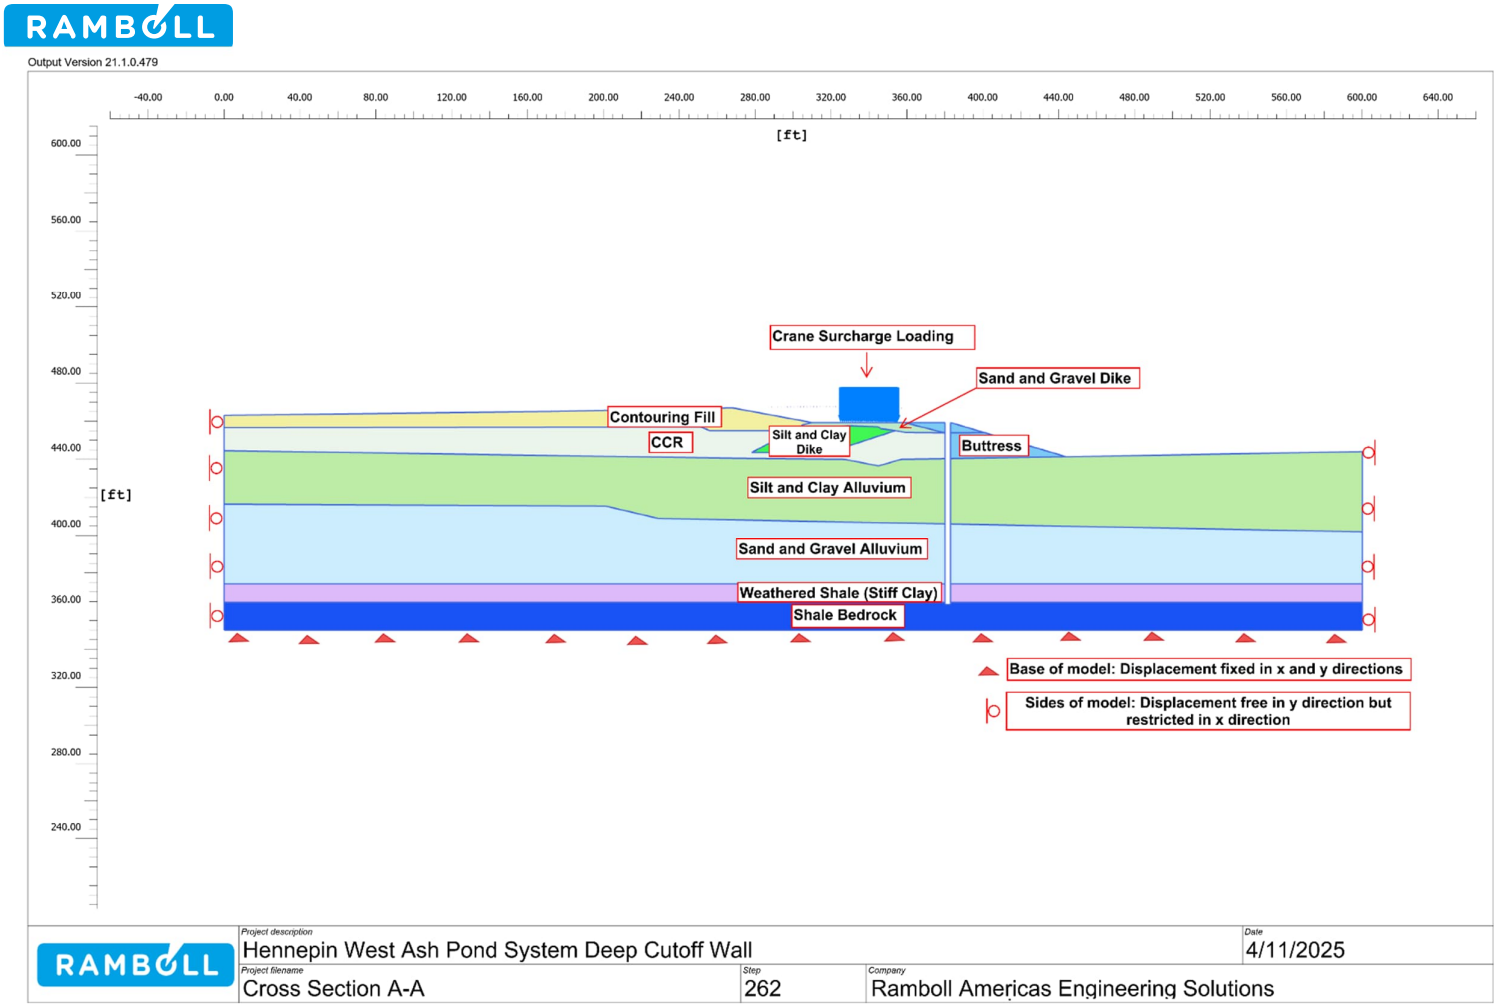

Figure 1. Numerical Model setup and boundary conditions for cross-section A-A'

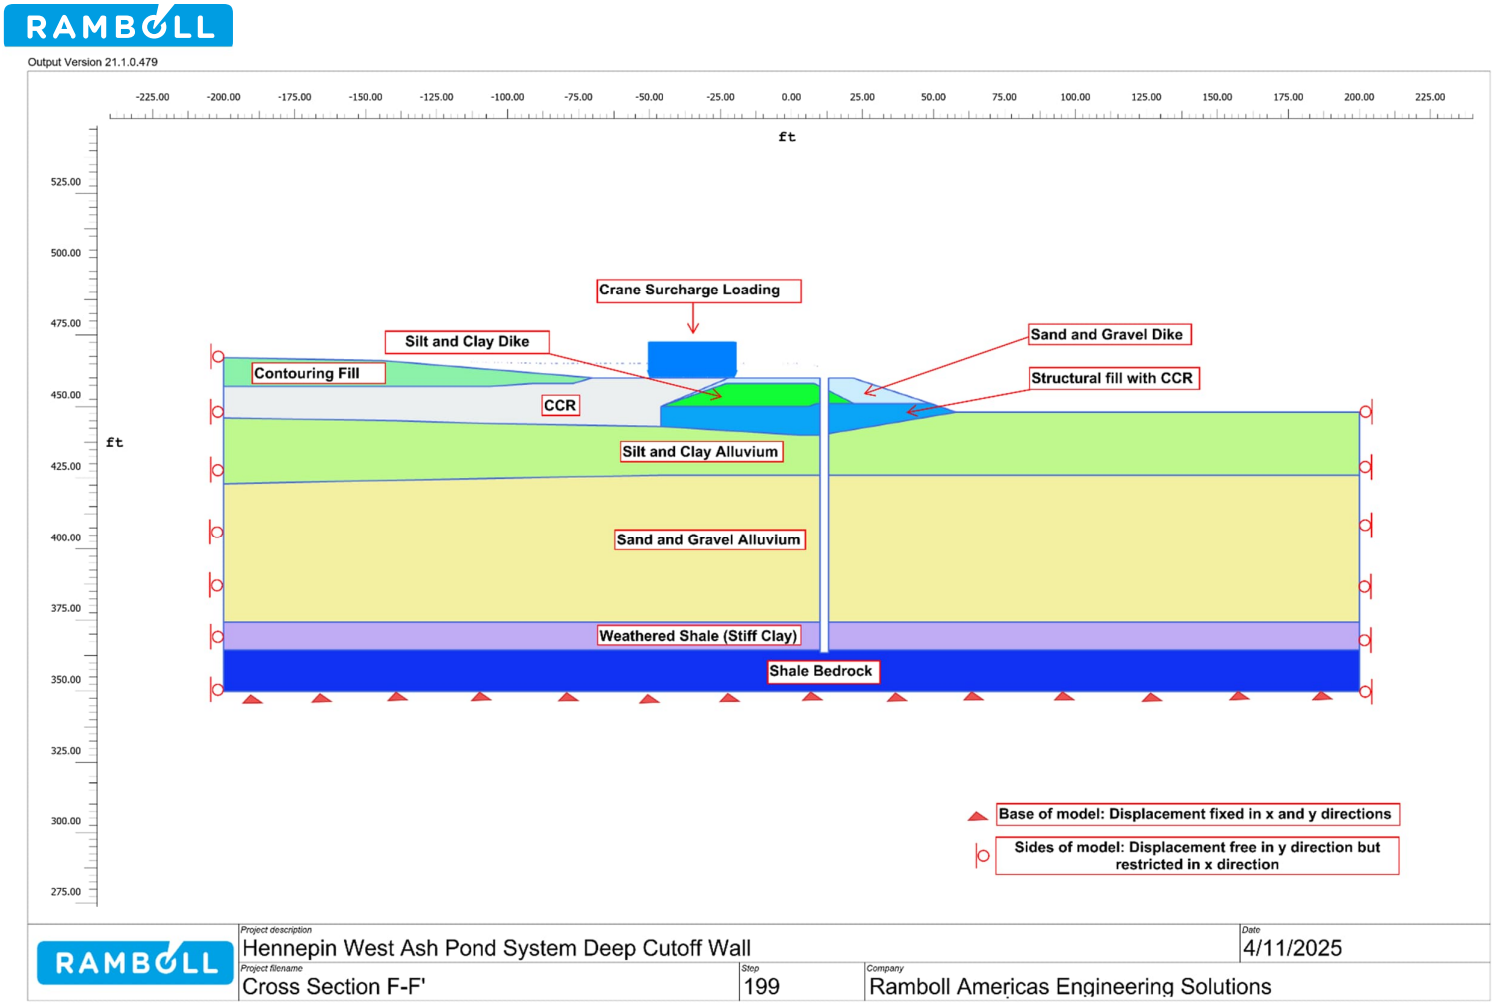

Figure 2. Numerical Model setup and boundary conditions for cross-section F-F'

4.4 Crane and Slurry Loading Surcharges

The crane used to install the slurry DCW was assumed to be a 110-ton unit (Manitowoc 11000, per the specification sheet in **Attachment B** to this calculation package), with a total working weight of approximately 198,5000 pounds, along with an additional 30,000 lbs of DCW installation equipment attached to the crane. The crane was assumed to be placed on rigid crane pads (i.e., heavy timbers) with a 30 ft footprint (in-plane of 2D model), resulting in a surcharge load of approximately 254 pounds per square foot per foot out of plane that was uniformly applied in Plaxis 2D. The crane mat was assumed to be positioned 25 feet inside of the inner edge of the slurry trench.

Slurry loading surcharge application began with the trench excavation phase. The slurry was modeled as a hydrostatic fluid surcharge (i.e., zero shear-strength), where it was represented as a hydrostatic pressure of the cement-bentonite slurry with a unit weight of 68 pounds per cubic foot (pcf), which was assigned based on Ramboll's experience. The hydrostatic fluid surcharge was applied to the trench sides and the bottom of the trench. The hydrostatic pressure was calculated based on the slurry unit weight and the height difference between the assumed working pad ground surface (460 ft elevation for cross section F – F' and 459.2 ft for cross section A – A') and the bottom elevation of the slurry trench. The model settings were also adjusted to verify that only the hydrostatic slurry pressure (i.e., 68 pcf) was applied in the trench, rather than applying both the hydrostatic slurry pressure and groundwater pressure (i.e., 62.4 pcf).

4.5 Model Stages

The staged construction process of the slurry trench DCW stability analysis in PLAXIS 2D followed a systematic sequence to simulate the stress-history of the WAPS embankments and CCR, starting prior to their construction and ending at the excavation and backfill process. This process included the following stages:

- **Stage 1: Prior to WAPS Construction**: This stage corresponds to site conditions prior to the construction of the WAPS. The geostatic stress state is established using the k_o-procedure, and groundwater conditions are set. This initial stage is based on the assumption that the initial stresses in a soil body are influenced by the weight of the soil, the water conditions and the history of its formation. All materials were assumed drained in this stage.
- **Stage 2: WAPS Initial Construction:** This stage represents the initial construction of the WAPS, which occurred in the 1950s and 1960s. It includes the corresponding stress changes, consolidation, and deformations induced in the foundation materials by these activities. The consolidation theory used follows Biot [16], Darcy's law for fluid flow [17] and elastic behavior of the soil skeleton are also assumed. This approach analyzes the fully coupled fluid and deformation without additional loading until all excess pore pressures have decreased or dissipated. It was assigned by activating elements of the CCR and dikes for a 20-year consolidation duration (as a simplifying assumption). All materials were assumed drained in this stage.
- **Stage 3: WAPS Dike Raise:** This stage is similar to Stage 2 represents the raise of the splitter dike between the former Old West Ash Pond and the former Old West Polishing Pond. It includes activating the dike raise and allowing a 20-year consolidation duration (as a simplifying assumption). All materials were assumed drained in this stage.
- **Stage 4: WAPS Closure:** This stage is similar to Stages 2 and 3 and represents closure of the WAPS, placement of contouring fill, and construction of a buttress between the Old West Ash Pond

and Old West Polishing Pond. It includes activating these materials and allowing a 10 year consolidation duration. Since the closure was completed in 2020, this assumes that the next stage will start around 2030. All materials were assumed drained in this stage.

- **Stage 5: Working Platform Construction:** This phase is 30 days of work pad excavation prior to slurry trench excavation. The weathered and competent shale bedrock, silt and clay alluvium, silt and clay dike fill, and buttress materials were assumed undrained for this stage. All other materials were assumed to be drained.
- **Stage 6: Deep Cutoff Wall Construction**: This stage represents placement of the crane, excavation of the slurry trench (after 30 days of work pad excavation), and concurrent backfill with a bentonite slurry. The excavation duration was set to 7-day period assuming, representing the period that the bentonite was assumed behave in a low-stress manner prior to initial curing and strength gain. Stress changes and DCW performance are monitored through plastic analysis and safety analysis conducted to assess potential failure modes. Material drainage assumptions were the same as Stage 5.

5 Design Criteria and Analysis Results

5.1 Design Criteria

Minimum safety factors for CCR surface impoundments are provided in 35 Illinois Administrative Code (I.A.C.) Part § 845.460(a) (Part 845) [18]. However, Part 845 does not specify minimum safety factors for temporary loading conditions applied to existing CCR surface impoundment dikes, like DCW construction. However, Part 845 does provide minimum safety factors for end-of-construction conditions for new CCR surface impoundment dikes. This is a different type of temporary loading condition that corresponds to the stability of a CCR impoundment dike immediately after construction, and typically utilized undrained shear strengths in applicable soil materials. The minimum safety factor required for this loading condition by Part 845 is 1.30.

The minimum safety factor for temporary DCW construction was assumed to be 1.30, in the absence of a specific regulatory guidance for temporary loading conditions for existing CCR surface impoundments. This is because the end-of-construction loading condition described in temporary loading conditions, the minimum end-of-construction safety factor for a new CCR surface impoundment was utilized for this assessment. This is because the 845.460(a) end-of-construction loading conditions also represents a temporary condition.

5.2 Safety Factor Assessment Results

The results of each of the evaluated cross sections slurry trench stability analyses is presented in **Table 5**. The factor of safety (FOS) was computed using the shear strength reduction method in Plaxis 2D [1], where shear strength parameters frictional angle and cohesion are successively reduced until excessive deformations occur, which are indicative of failure (i.e., a limit state). Safety factors were estimated for both pre-construction conditions and conditions after the slurry trench have been installed. Detailed results output from Plaxis 2D is provided in **Attachment D** to this calculation package for each of the evaluated cross sections.

5.3 Deformation and Strain Assessment Results

All deformations are presented as phase displacements from the Plaxis 2D [1] output. Phase deformations represent displacement changes occurring between the end of the previous phase and the end of the current phase. For this assessment, the phase deformations represent deformations between the WAPS construction

phase and the trench excavation phase, or deformations that are expected to occur during placement of the crane and construction of the deep cutoff wall. The output was displayed as phase displacement (|Pu|), which illustrates the magnitude of movement in that calculated phase, and as individual displacement components (Pu_x and Pu_y), which separately represent the horizontal and vertical displacements computed in that phase or calculation step.

Similarly, phase strains were also exported to provide an assessment of accumulated strain increments in the whole calculation phase, relative to the preceding calculation phase. As with the deformation assessment, this corresponds to strains between the end of the WAPS construction phase and the trench excavation phase, or strains that are expected to occur during placement of the crane and construction of the deep cutoff wall. The output was presented as deviatoric strain ($P\varepsilon_q$), which corresponds to shear deformation and was used to identify potential zones of concentrated shear strain, which could be indicative of failure zones.

Table 6 provides a summary of the estimated phase deformations and deviatoric strains during trench construction. The results are presented in terms of maximum vertical deformation of the crane pad (i.e., settlement), maximum deformation of the soil mass into the slurry trench, and maximum deviatoric strains within the soil mass. Detailed results output, with annotations indicating deformations and strains, are provided in **Attachment D** of this calculation package.

Table 5. Factor of Safety results of slurry trench stability analyses

Calculated Factor of Safety				
Cross-Section	Safety Factor Before Trench Excavation	Safety Factor After Trench Excavation	Minimum Allowable Safety Factor per 845.460(a)	Meets / Does Not Meet 845.460(a) Criteria
A-A'	1.88	1.33	1.30	Meets
F-F'	1.77	1.30		Meets

Table 6. Deformation and deviatoric strain results after slurry trench stability analyses

Estimated Deformations							Estimated Deviatoric Strain			
Cross Section	Crane Pad Side of DCW				Outer Dike Side of DCW		Crane Pad Side of DCW		Outer Dike Side of DCW	
	Max. Vertical crane pad deformations (i.e., settlement)[1]		Max. Horizontal deformation of the slurry trench sidewall[2]		Max. Horizontal deformation of slurry trench sidewall[2]		Max. Localized deviatoric strain along trench sidewall		Max. Localized deviatoric strain along slurry trench sidewall	
	ft	in	ft	in	ft	in	unitless	%	unitless	%
A - A'	0.16	1.9	0.16	1.9	0.08	1.0	0.02	2	0	0
F- F'	0.08	1.0	0.08	1.0	0.04	0.5	0.024	2.4	0.012	1.2

Notes

1. Positive vertical deformation represents settlement (i.e., moving downward in elevation).
2. Positive horizontal deformation represents horizontal displacements of the trench sidewall into the slurry trench.

6 Conclusions and Recommendations

The preliminary, concept-level stability analysis indicates that safety factors during trench construction are expected to meet or exceed the minimum 1.30 requirements listed in 845.460(a) [18]. During construction, predicted deformations of the crane pad are expected to be on the order of 1 to 2 inches of settlement, while deformation of the trench sidewalls into the trench are expected to be on the order of 1 to 2 inches. These deformations are relatively minor and are not expected to result in structural distress of the crane pad or the WAPS embankments. Furthermore, the estimated deviatoric strains around the order of 1 to 2% occur in localized areas at the bottom of the excavated trench and at material interfaces near the bottom of the trench.

Additional investigation and analysis should be performed during final design of the DCW, after a construction permit has been issued, to further refine the assessment. This should include collecting additional subsurface data along the DCW alignment to refine the input parameters for the numerical models. The analysis should also be updated based on the actual expected slurry densities, crane weight and geometry, and final crane pad details. This may include analyzing additional cross-sections beyond the two cross-sections presented herein. The analyses should retain the same design criteria of providing a safety factor of at least 1.30 while limiting expected deformations and induced strains to tolerable levels that are unlikely to result in significant distress to either the crane pad or the WPAS embankments. Three-dimensional analyses could also be warranted to consider three-dimensional stabilization effects that are neglected by the conservative two-dimensional analysis, which would be expected to reduce estimated deformations and shear strains, while increasing calculated safety factors above values presented in this calculation package.

Additionally, a geotechnical instrumentations system should be developed to monitor the crane pad and slurry trench during DCW construction. The instrumentation system may include instruments such as piezometers, inclinometers, and settlement measurement devices. During construction, the system should be monitored at near-continuous intervals, and actual embankment and slurry trench performance should be compared to expected performance obtained from the refined stability analyses completed as part of final design. Threshold levels should be developed to trigger additional investigation and/or work stoppages in the event that instrument readings and/or other observations indicate signs of adverse embankment and/or slurry trench performance.

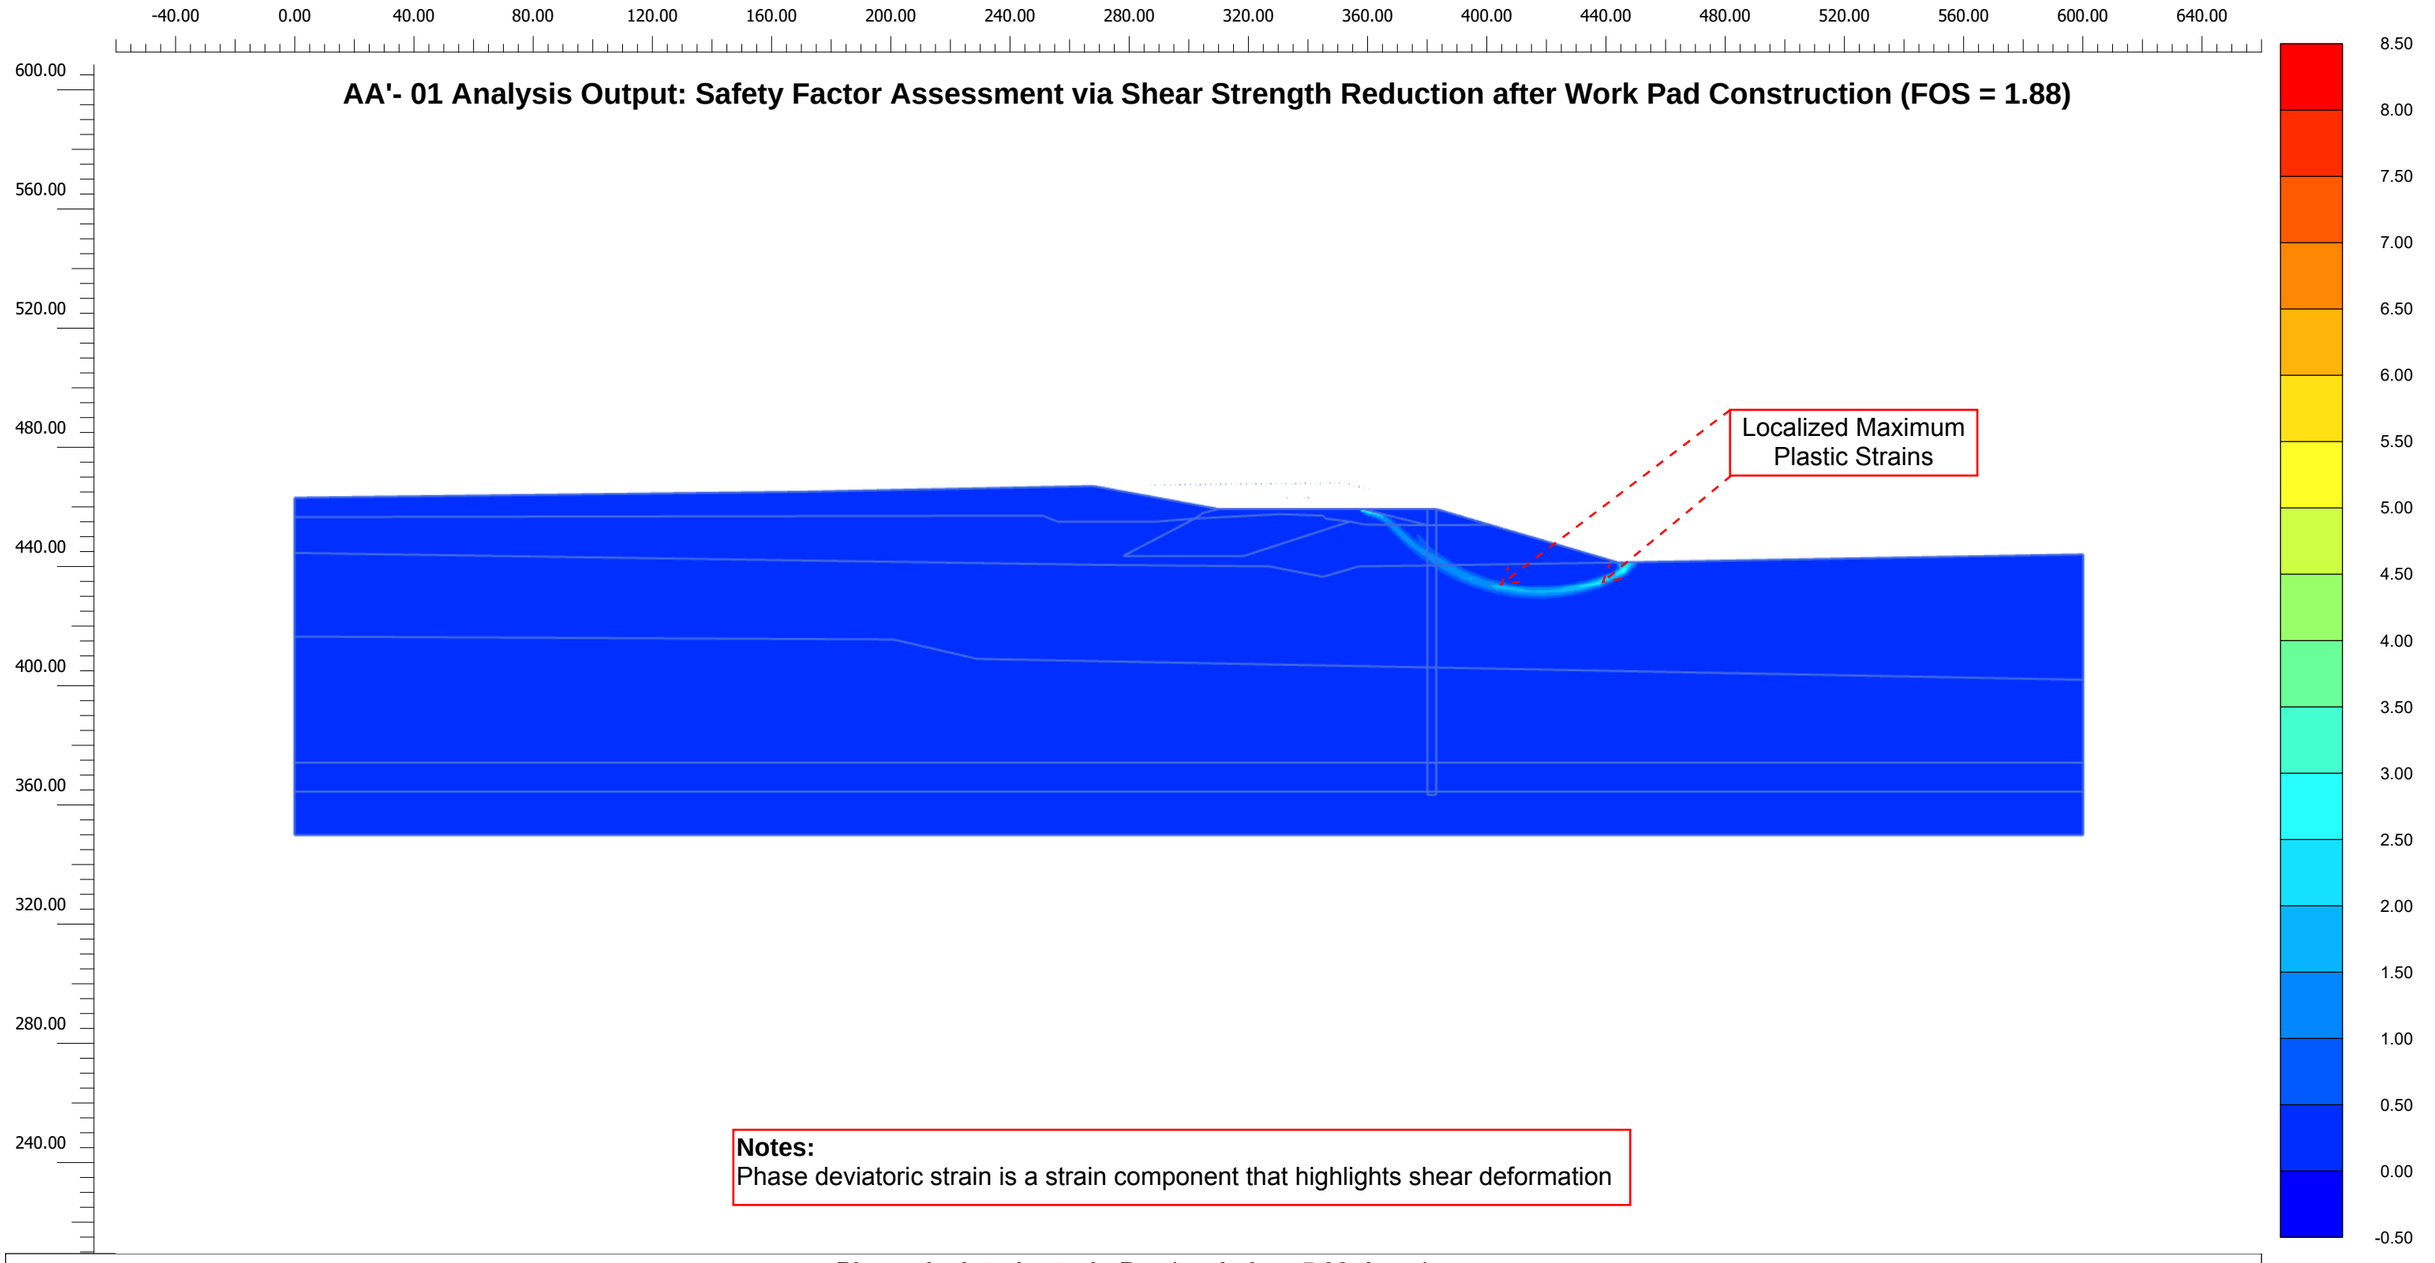
Results

Table 8. Summary of Plaxis Results Outputs

Cross-Section	Phase	New Analysis ID	New Description
A-A'	Work Pad Construction Phase	AA-01	Safety Factor Assessment via Shear Strength Reduction after Work Pad Construction (FOS = 1.88)
	Trench Excavation Phase	AA-02	Safety Factor Assessment via Shear Strength Reduction after Trench Excavation (FOS = 1.33)
		AA-03	Estimated Deviatoric Strain after Trench Excavation
		AA-04	Estimated Horizontal Displacements after Trench Excavation
		AA-05	Estimated Vertical Displacements after Trench Excavation
F-F'	Work Pad Construction Phase	FF-01	Safety Factor Assessment via Shear Strength Reduction after Work Pad Construction (FOS = 1.77)
	Trench Excavation Phase	FF-02	Safety Factor Assessment via Shear Strength Reduction after Trench Excavation (FOS = 1.30)
		FF-03	Estimated Deviatoric Strain after Trench Excavation
		FF-04	Estimated Horizontal Displacements after Trench Excavation
		FF-05	Estimated Vertical Displacements after Trench Excavation

Output Version 21.1.0.479

AA'- 01 Analysis Output: Safety Factor Assessment via Shear Strength Reduction after Work Pad Construction (FOS = 1.88)



Notes:
Phase deviatoric strain is a strain component that highlights shear deformation

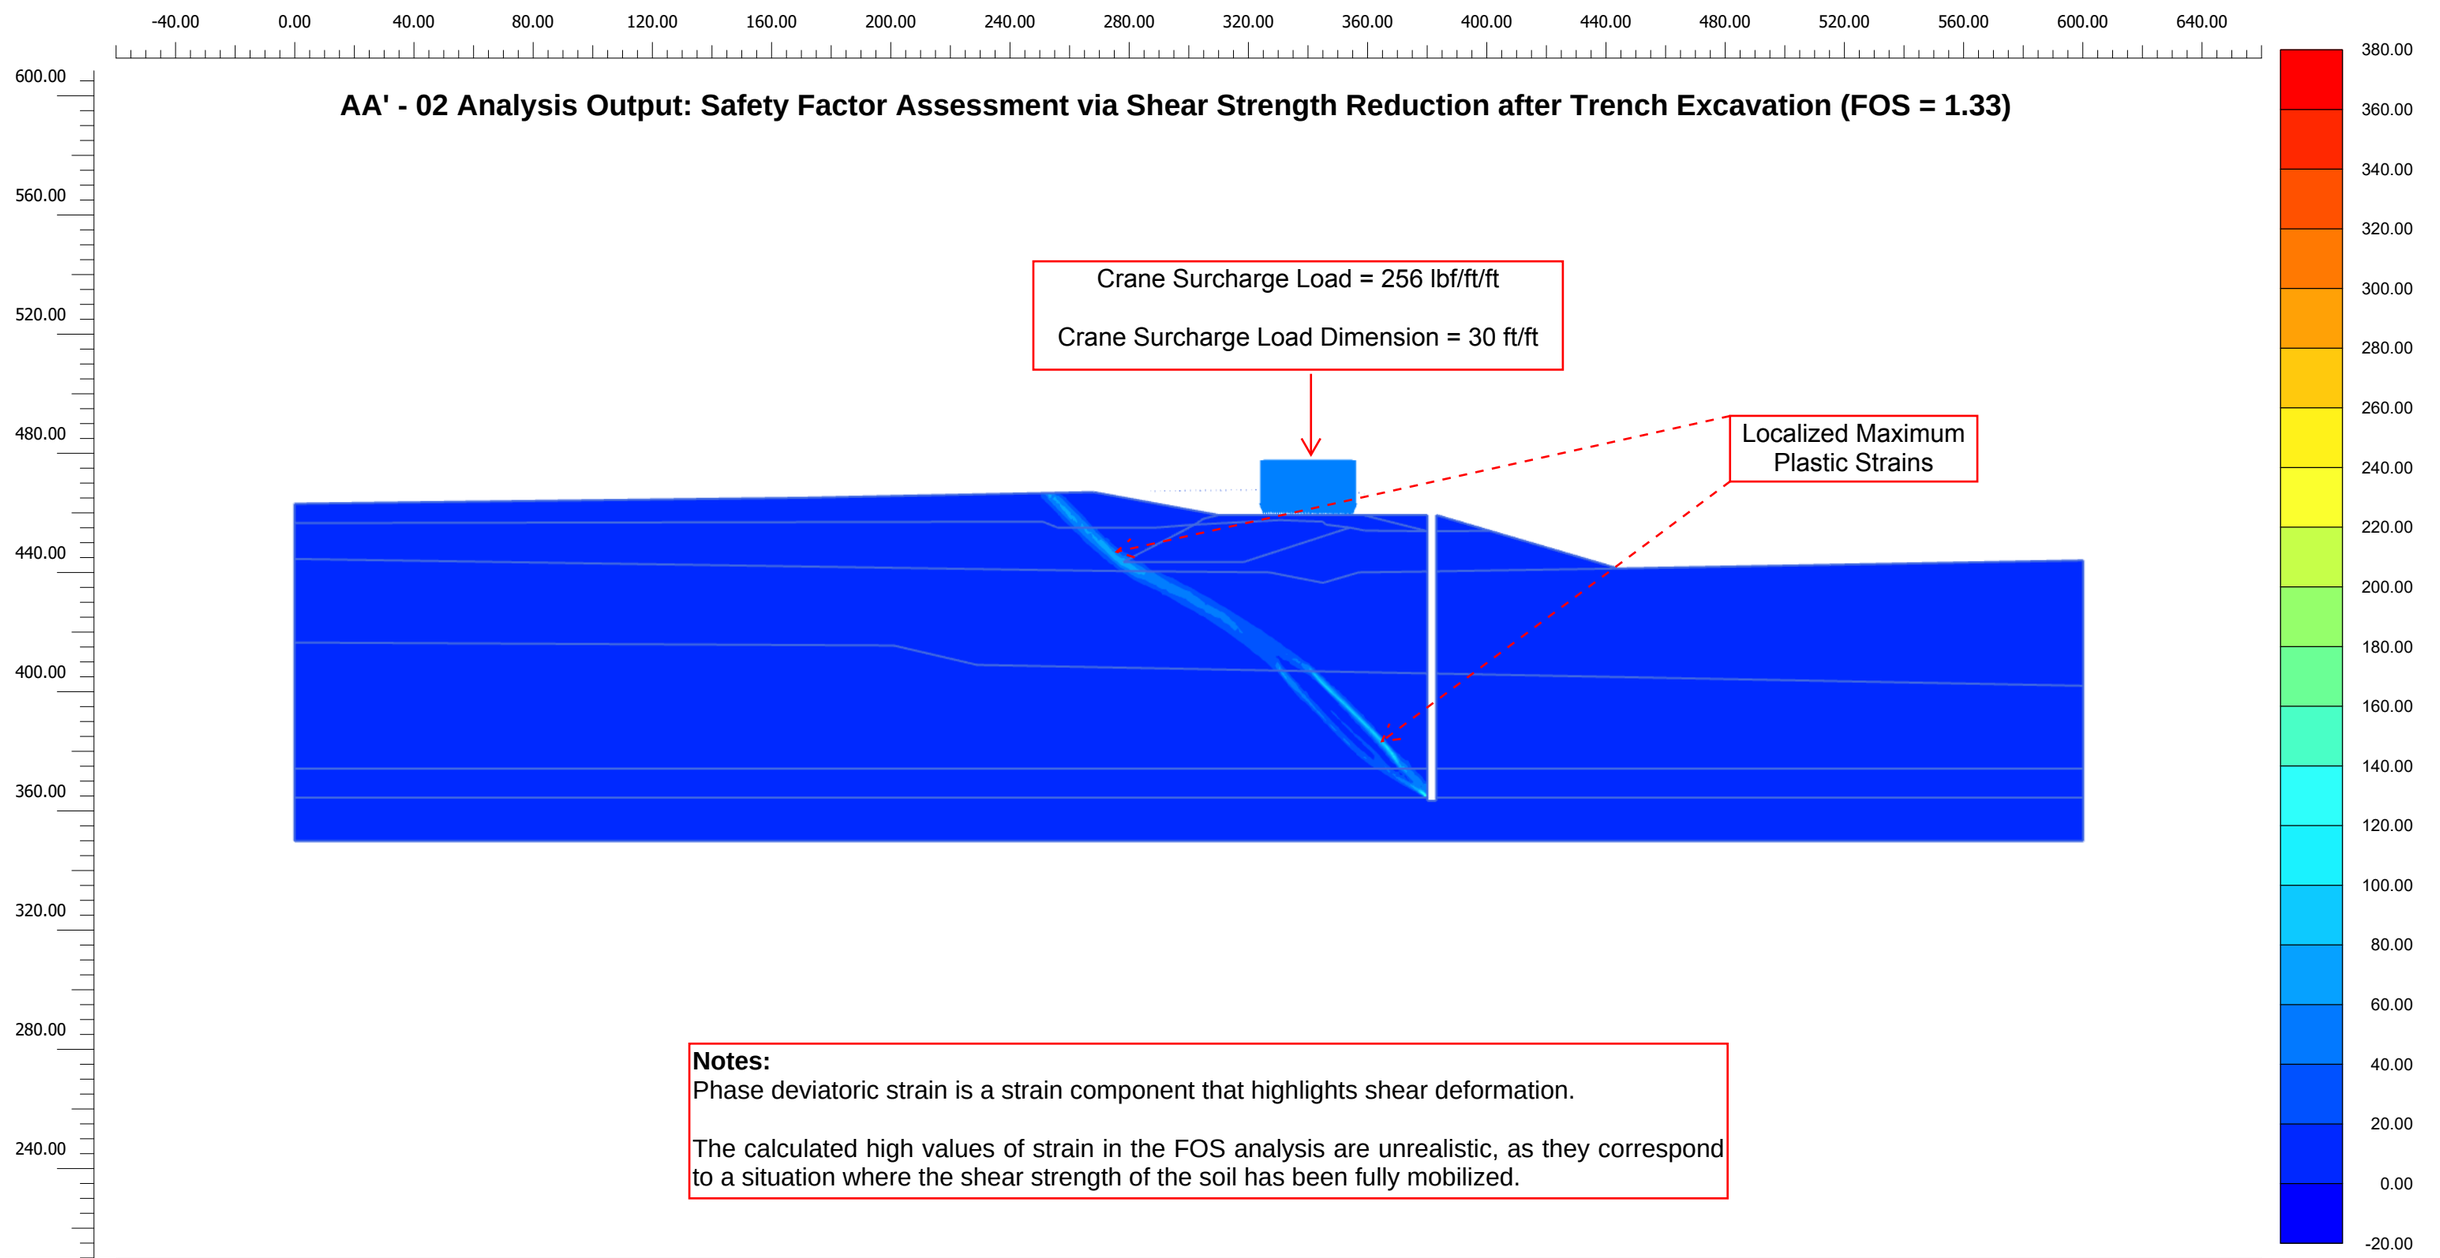
Phase deviatoric strain $P\gamma_s$ (scaled up 5.00 times)

Maximum value = 8.148 (Element 344 at Node 9429)

Minimum value = $0.7139*10^{-9}$ (Element 3114 at Node 26258)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section A-A'	*Step* 462	*Company* Ramboll Americas Engineering Solutions

AA' - 02 Analysis Output: Safety Factor Assessment via Shear Strength Reduction after Trench Excavation (FOS = 1.33)



Notes:
Phase deviatoric strain is a strain component that highlights shear deformation.

The calculated high values of strain in the FOS analysis are unrealistic, as they correspond to a situation where the shear strength of the soil has been fully mobilized.

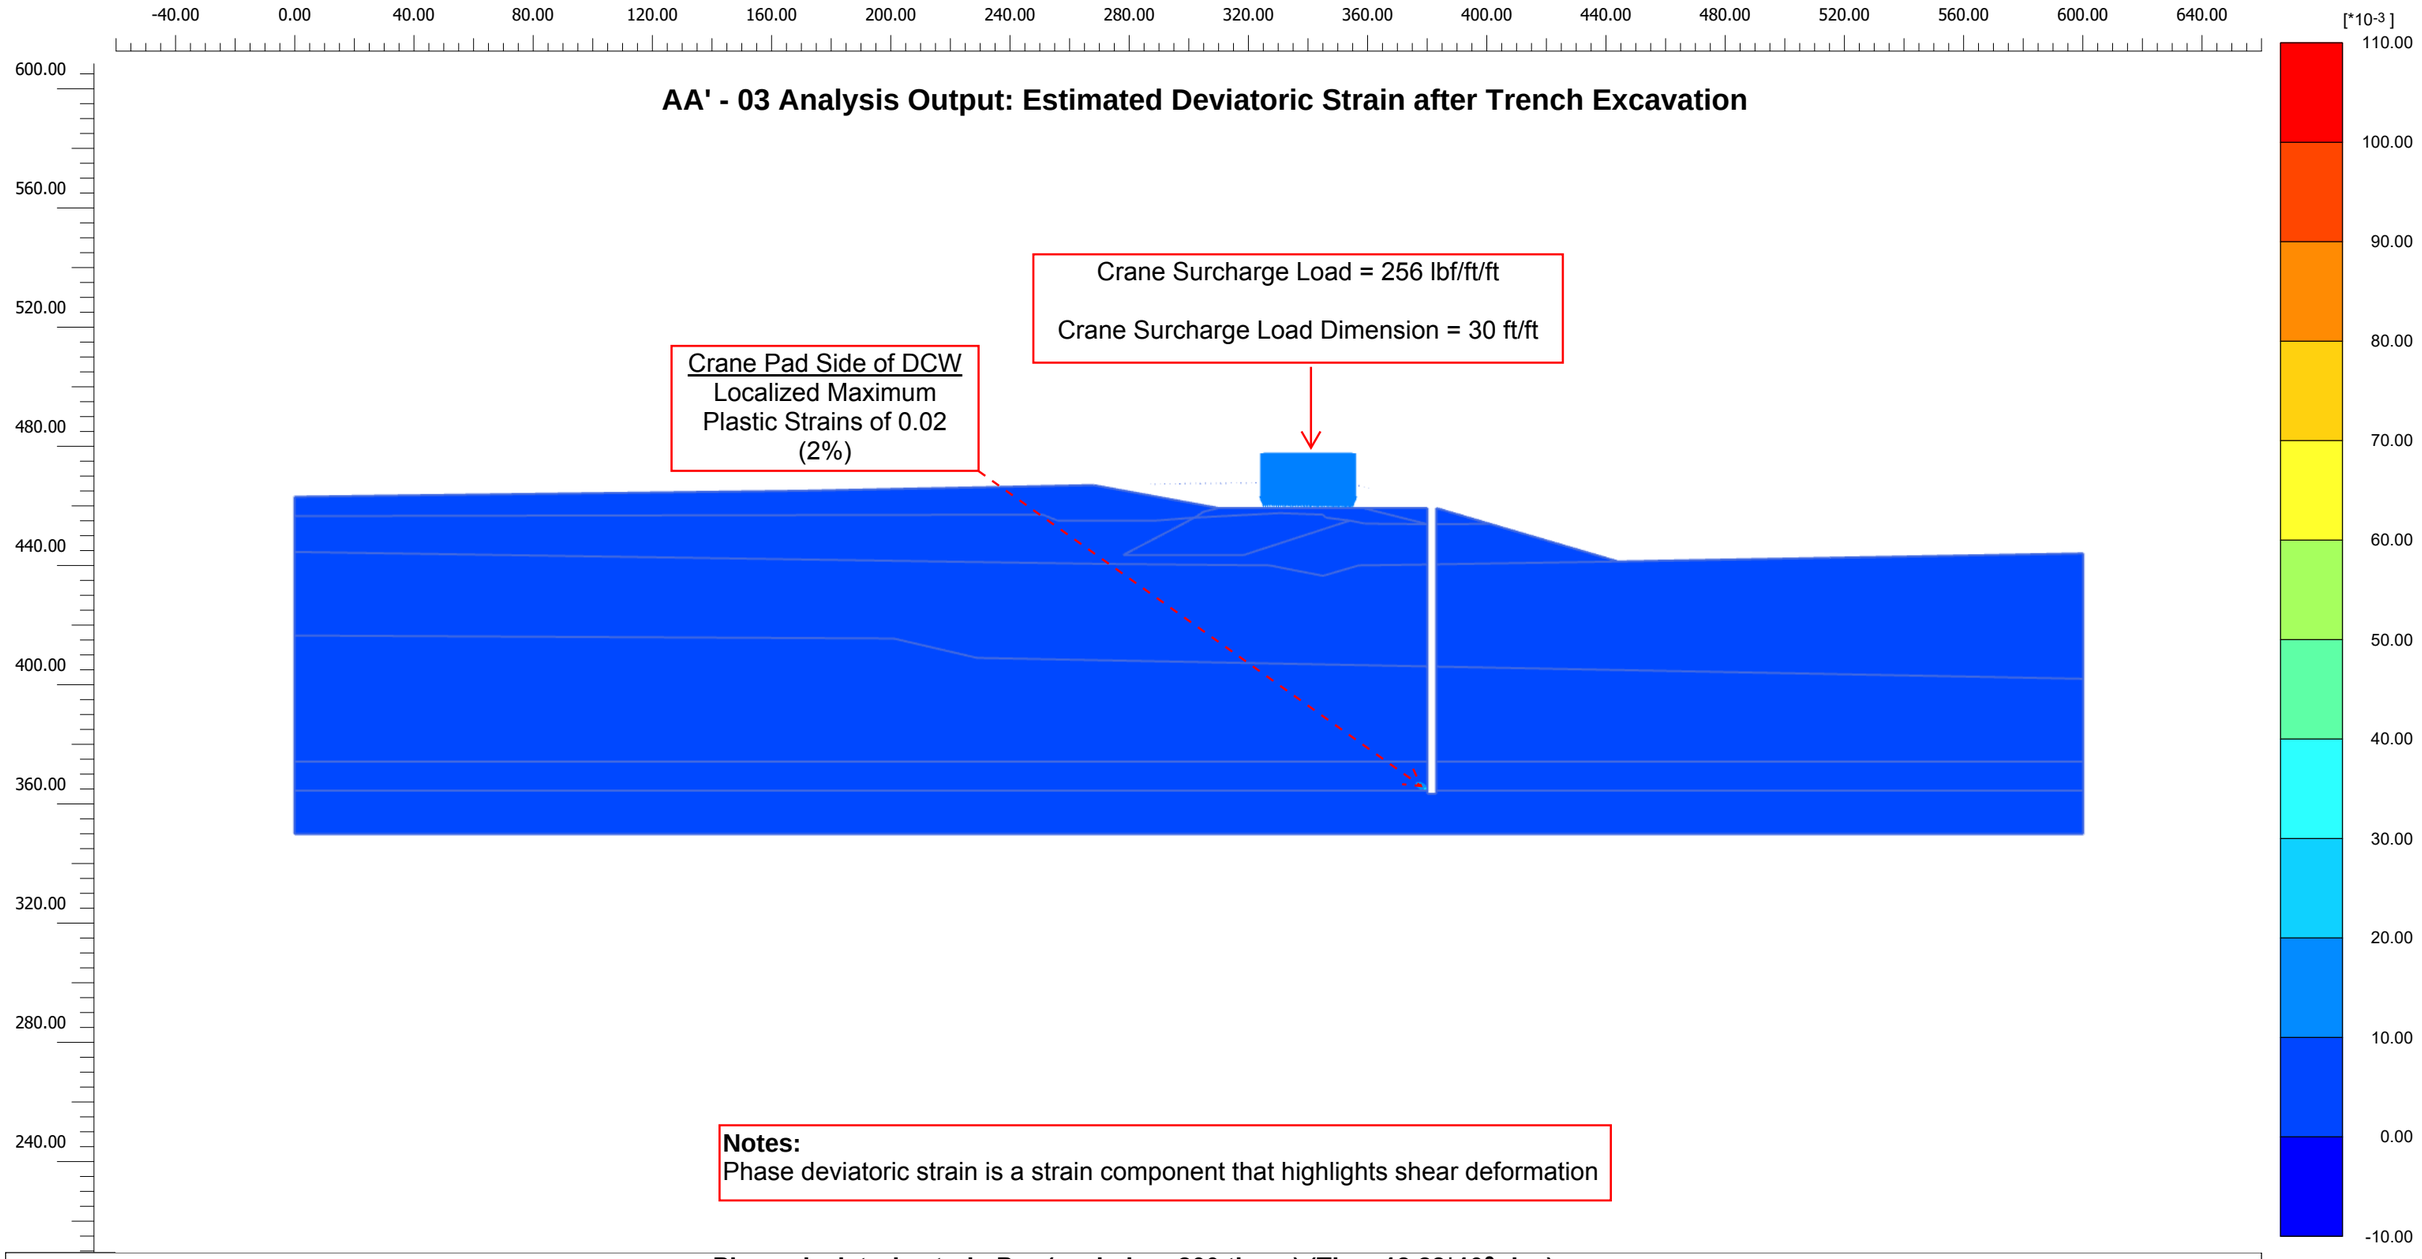
Phase deviatoric strain $P\gamma_s$ (scaled up 0.0500 times)

Maximum value = 361.0 (Element 2907 at Node 13817)

Minimum value = $1.381*10^{-9}$ (Element 304 at Node 6196)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section A-A'	*Step* 362	*Company* Ramboll Americas Engineering Solutions

AA' - 03 Analysis Output: Estimated Deviatoric Strain after Trench Excavation



Notes:
Phase deviatoric strain is a strain component that highlights shear deformation

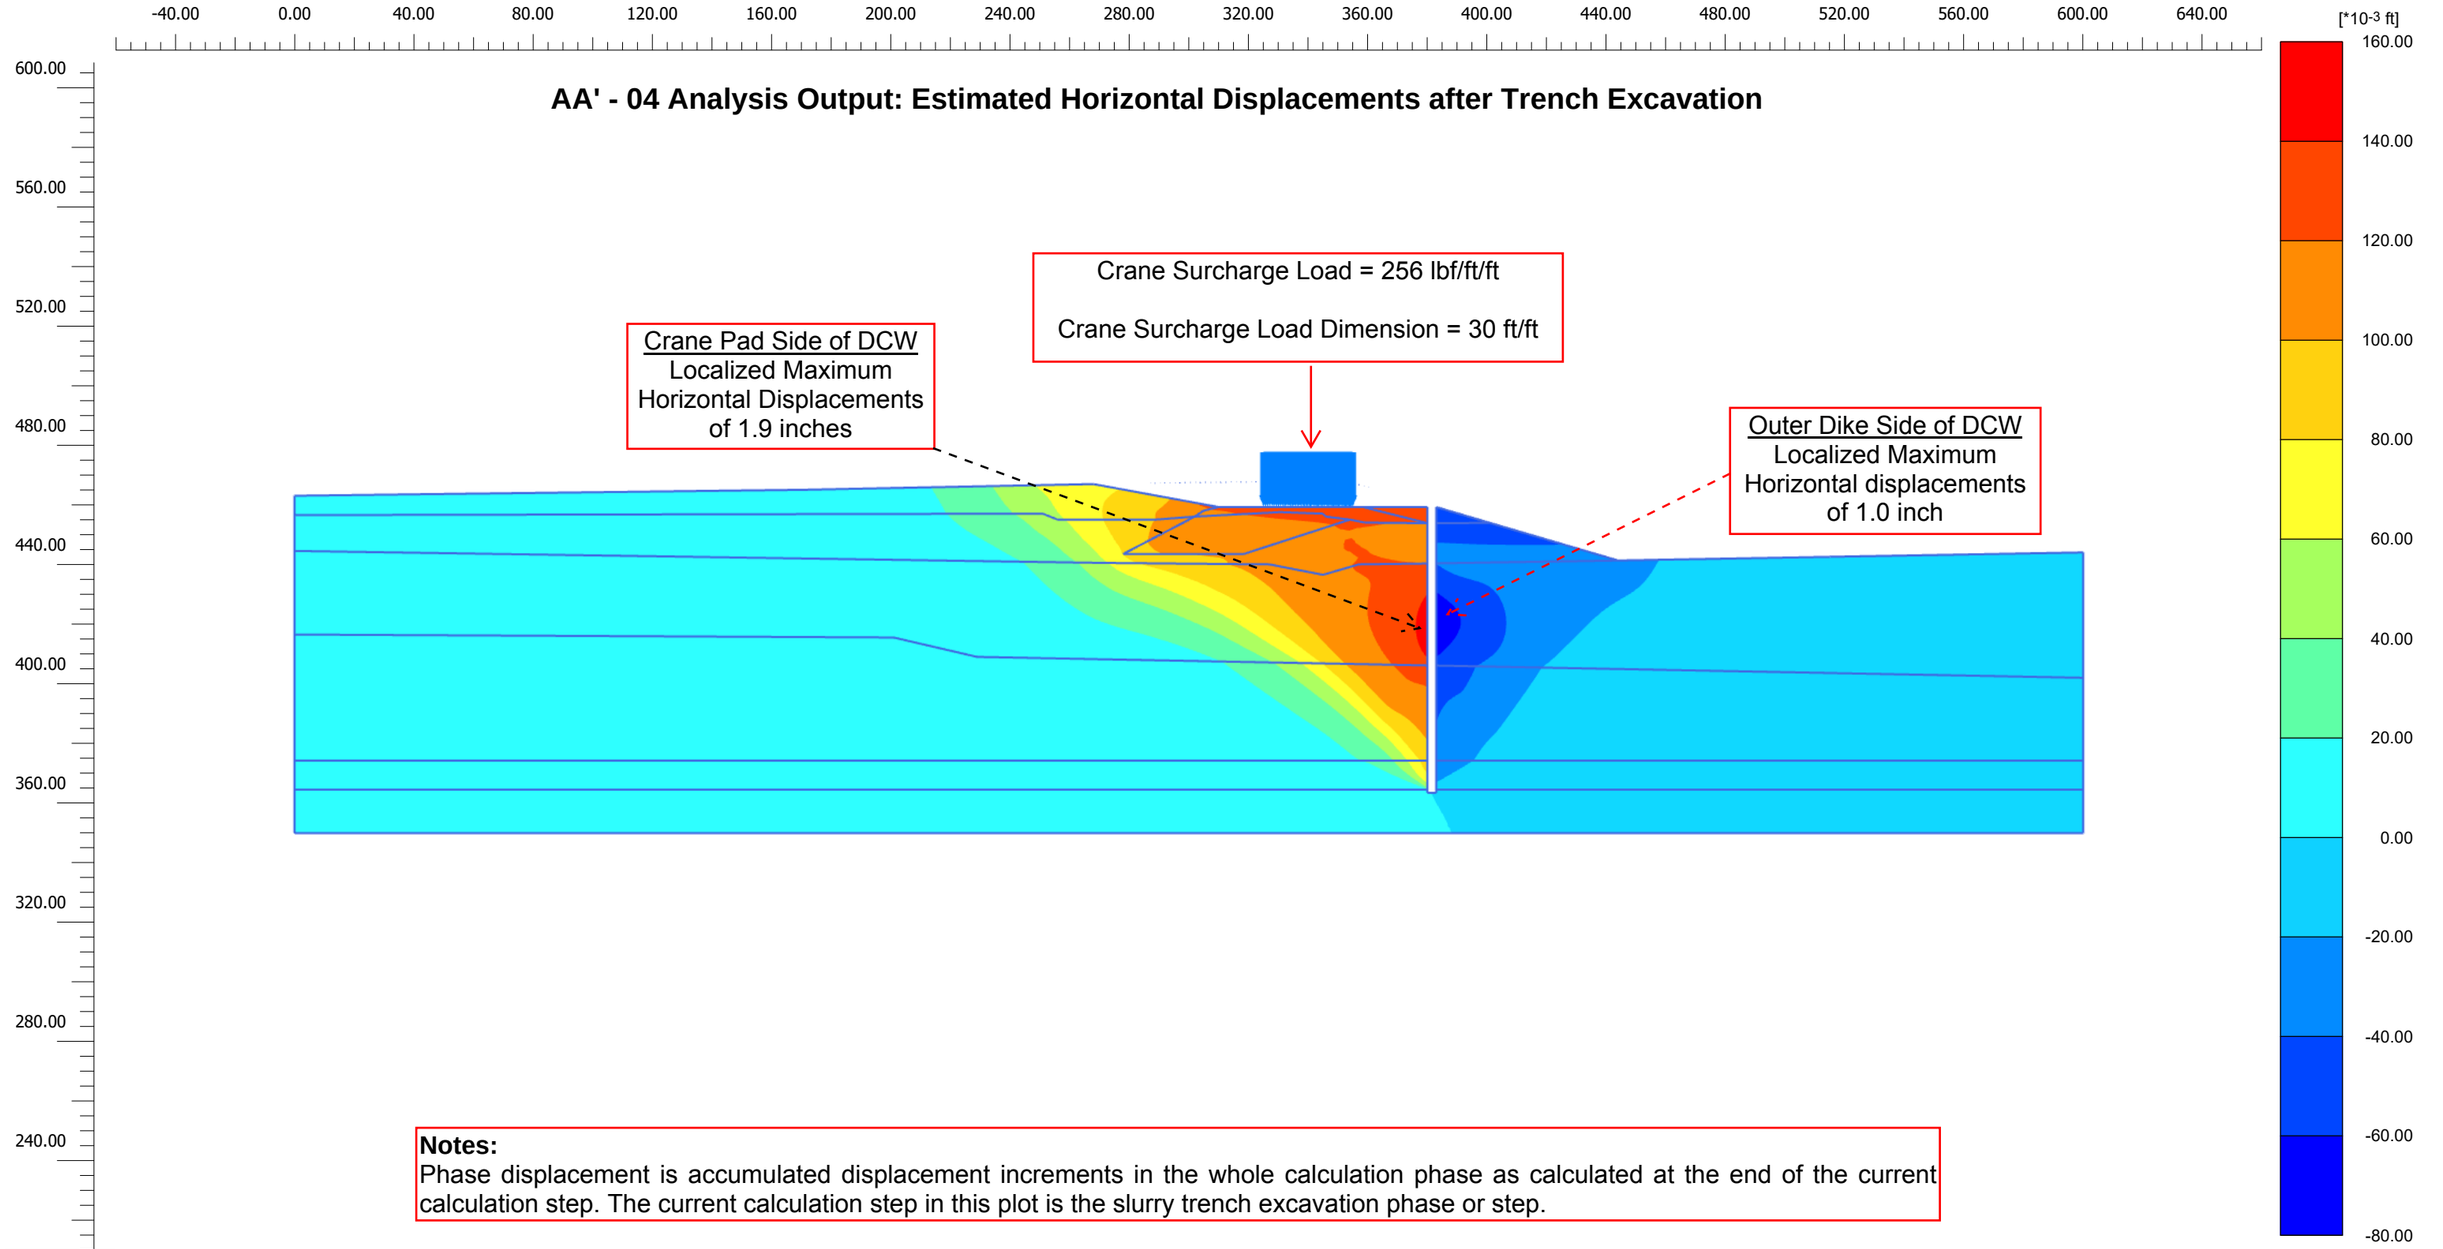
Phase deviatoric strain $P\gamma_s$ (scaled up 200 times) (Time $18.28*10^3$ day)

Maximum value = 0.1021 (Element 2907 at Node 13817)

Minimum value = $4.816*10^{-9}$ (Element 3143 at Node 26287)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section A-A'	*Step* 262	*Company* Ramboll Americas Engineering Solutions

AA' - 04 Analysis Output: Estimated Horizontal Displacements after Trench Excavation



Notes:
Phase displacement is accumulated displacement increments in the whole calculation phase as calculated at the end of the current calculation step. The current calculation step in this plot is the slurry trench excavation phase or step.

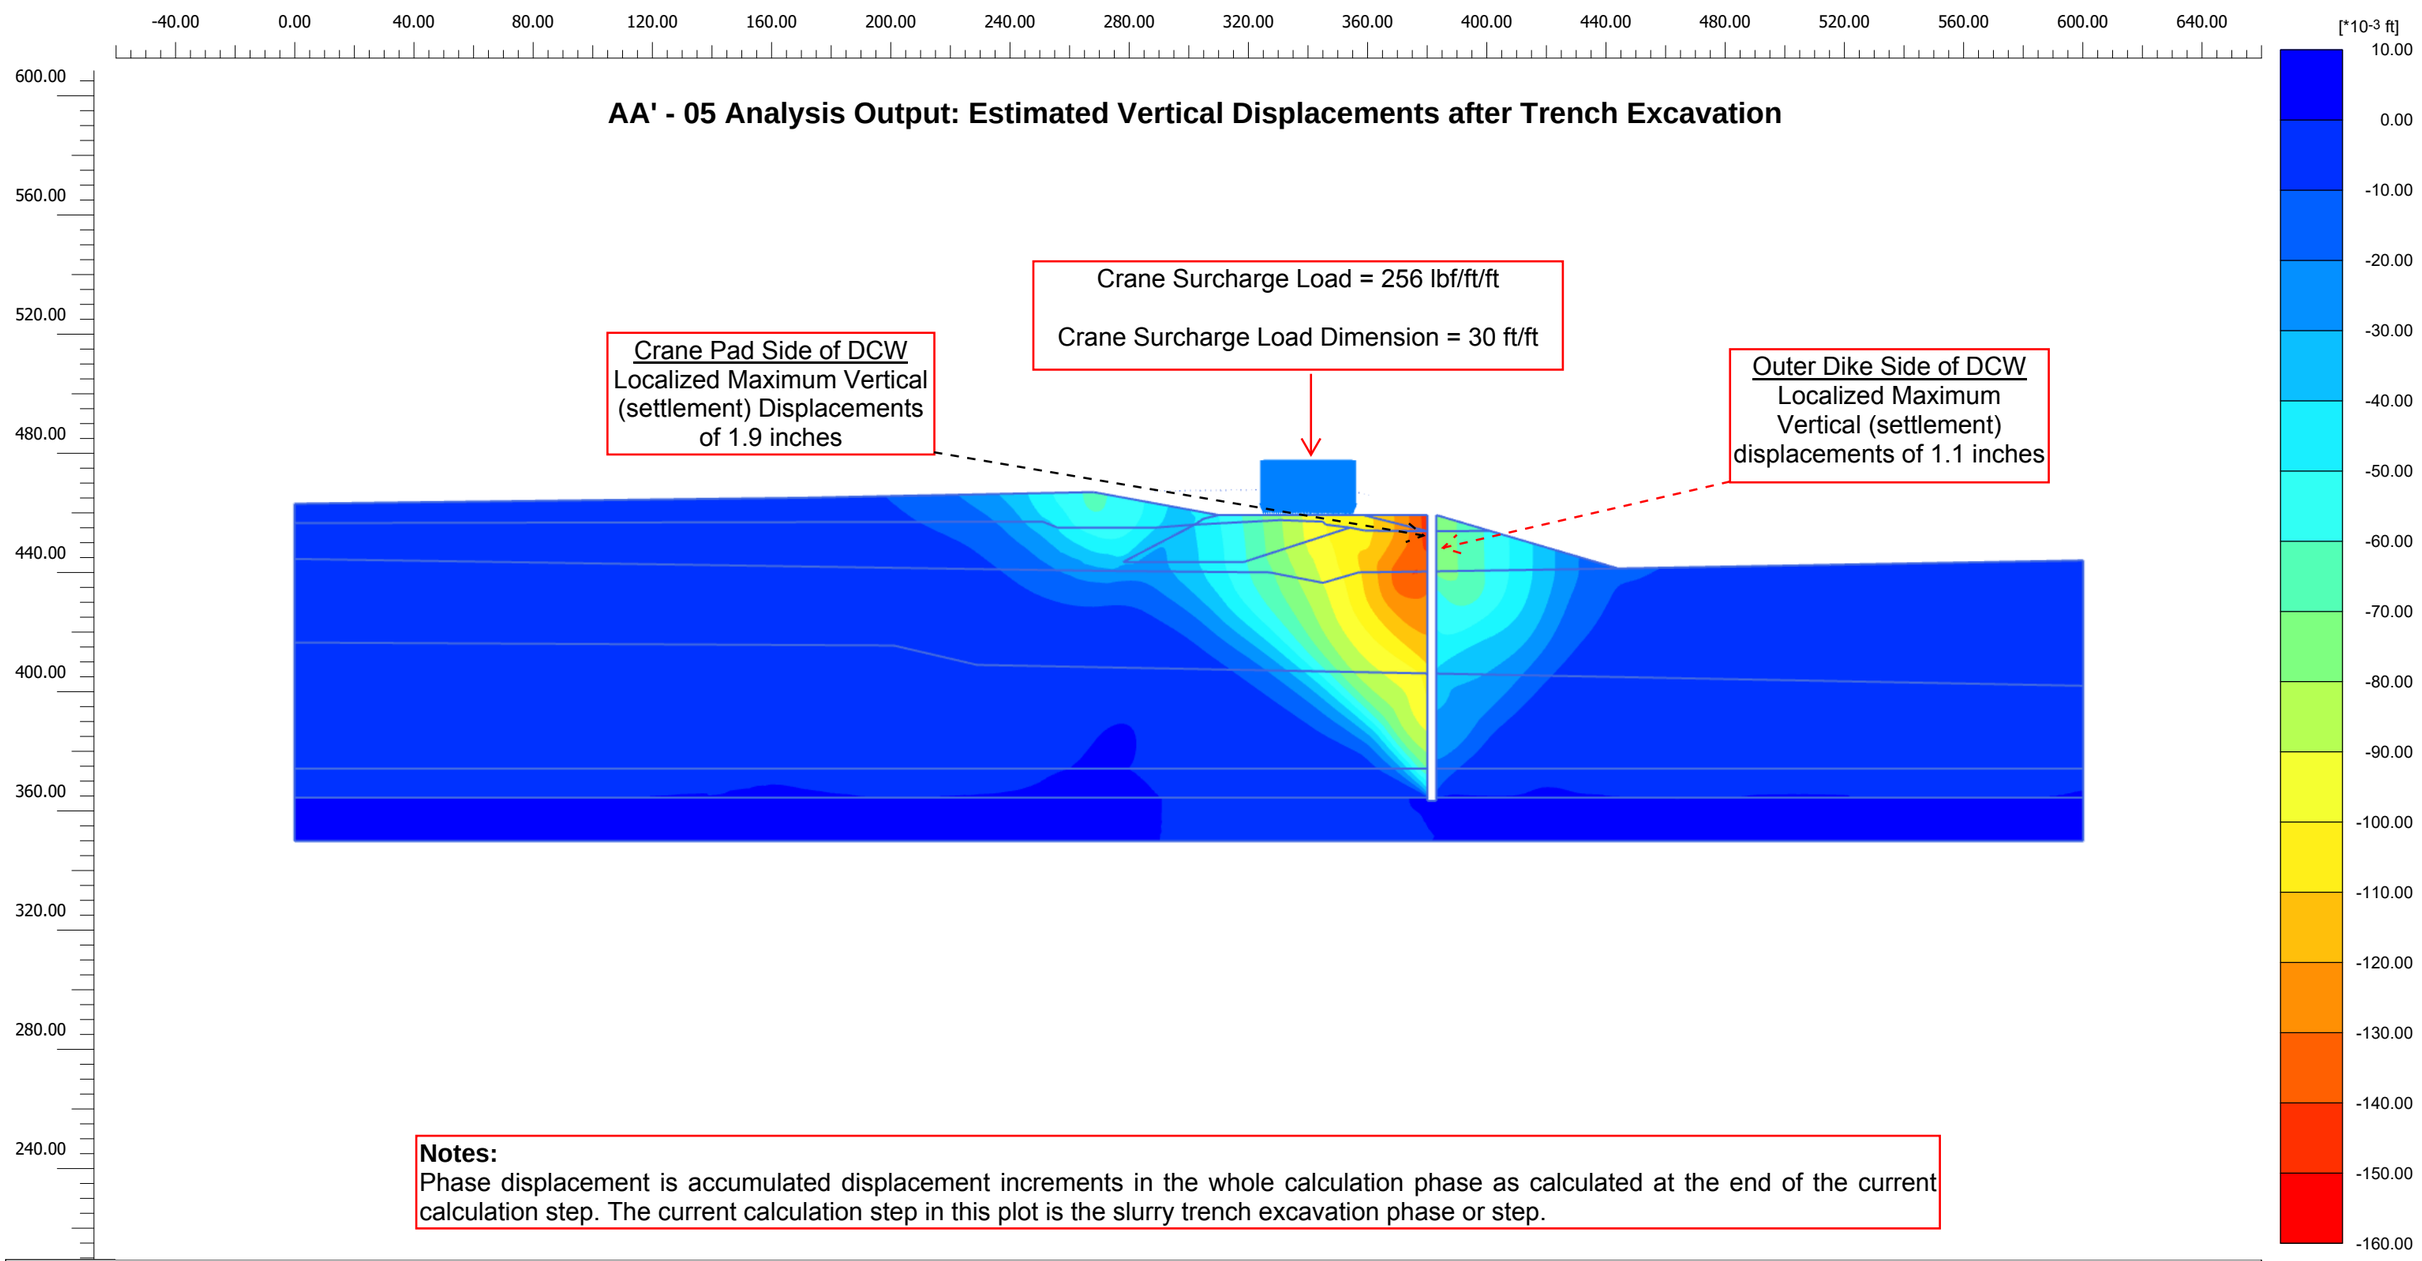
Phase displacements Pu_x (scaled up 50.0 times) (Time $18.28*10^3$ day)

Maximum value = 0.1441 ft (Element 1161 at Node 7830)

Minimum value = -0.06727 ft (Element 1543 at Node 7285)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section A-A'	*Step* 262	*Company* Ramboll Americas Engineering Solutions

AA' - 05 Analysis Output: Estimated Vertical Displacements after Trench Excavation



Notes:
Phase displacement is accumulated displacement increments in the whole calculation phase as calculated at the end of the current calculation step. The current calculation step in this plot is the slurry trench excavation phase or step.

Phase displacements Pu_y (scaled up 100 times) (Time $18.28*10^3$ day)

Maximum value = $0.08934*10^{-3}$ ft (Element 2687 at Node 19856)

Minimum value = -0.1513 ft (Element 684 at Node 7017)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section A-A'	*Step* 262	*Company* Ramboll Americas Engineering Solutions

Output Version 21.1.0.479

FF' - 01 Analysis Output: Safety Factor Assessment via Shear Strength Reduction after Work Pad Construction (FOS) = 1.77

Notes:
Phase deviatoric strain is a strain component that highlights shear deformation

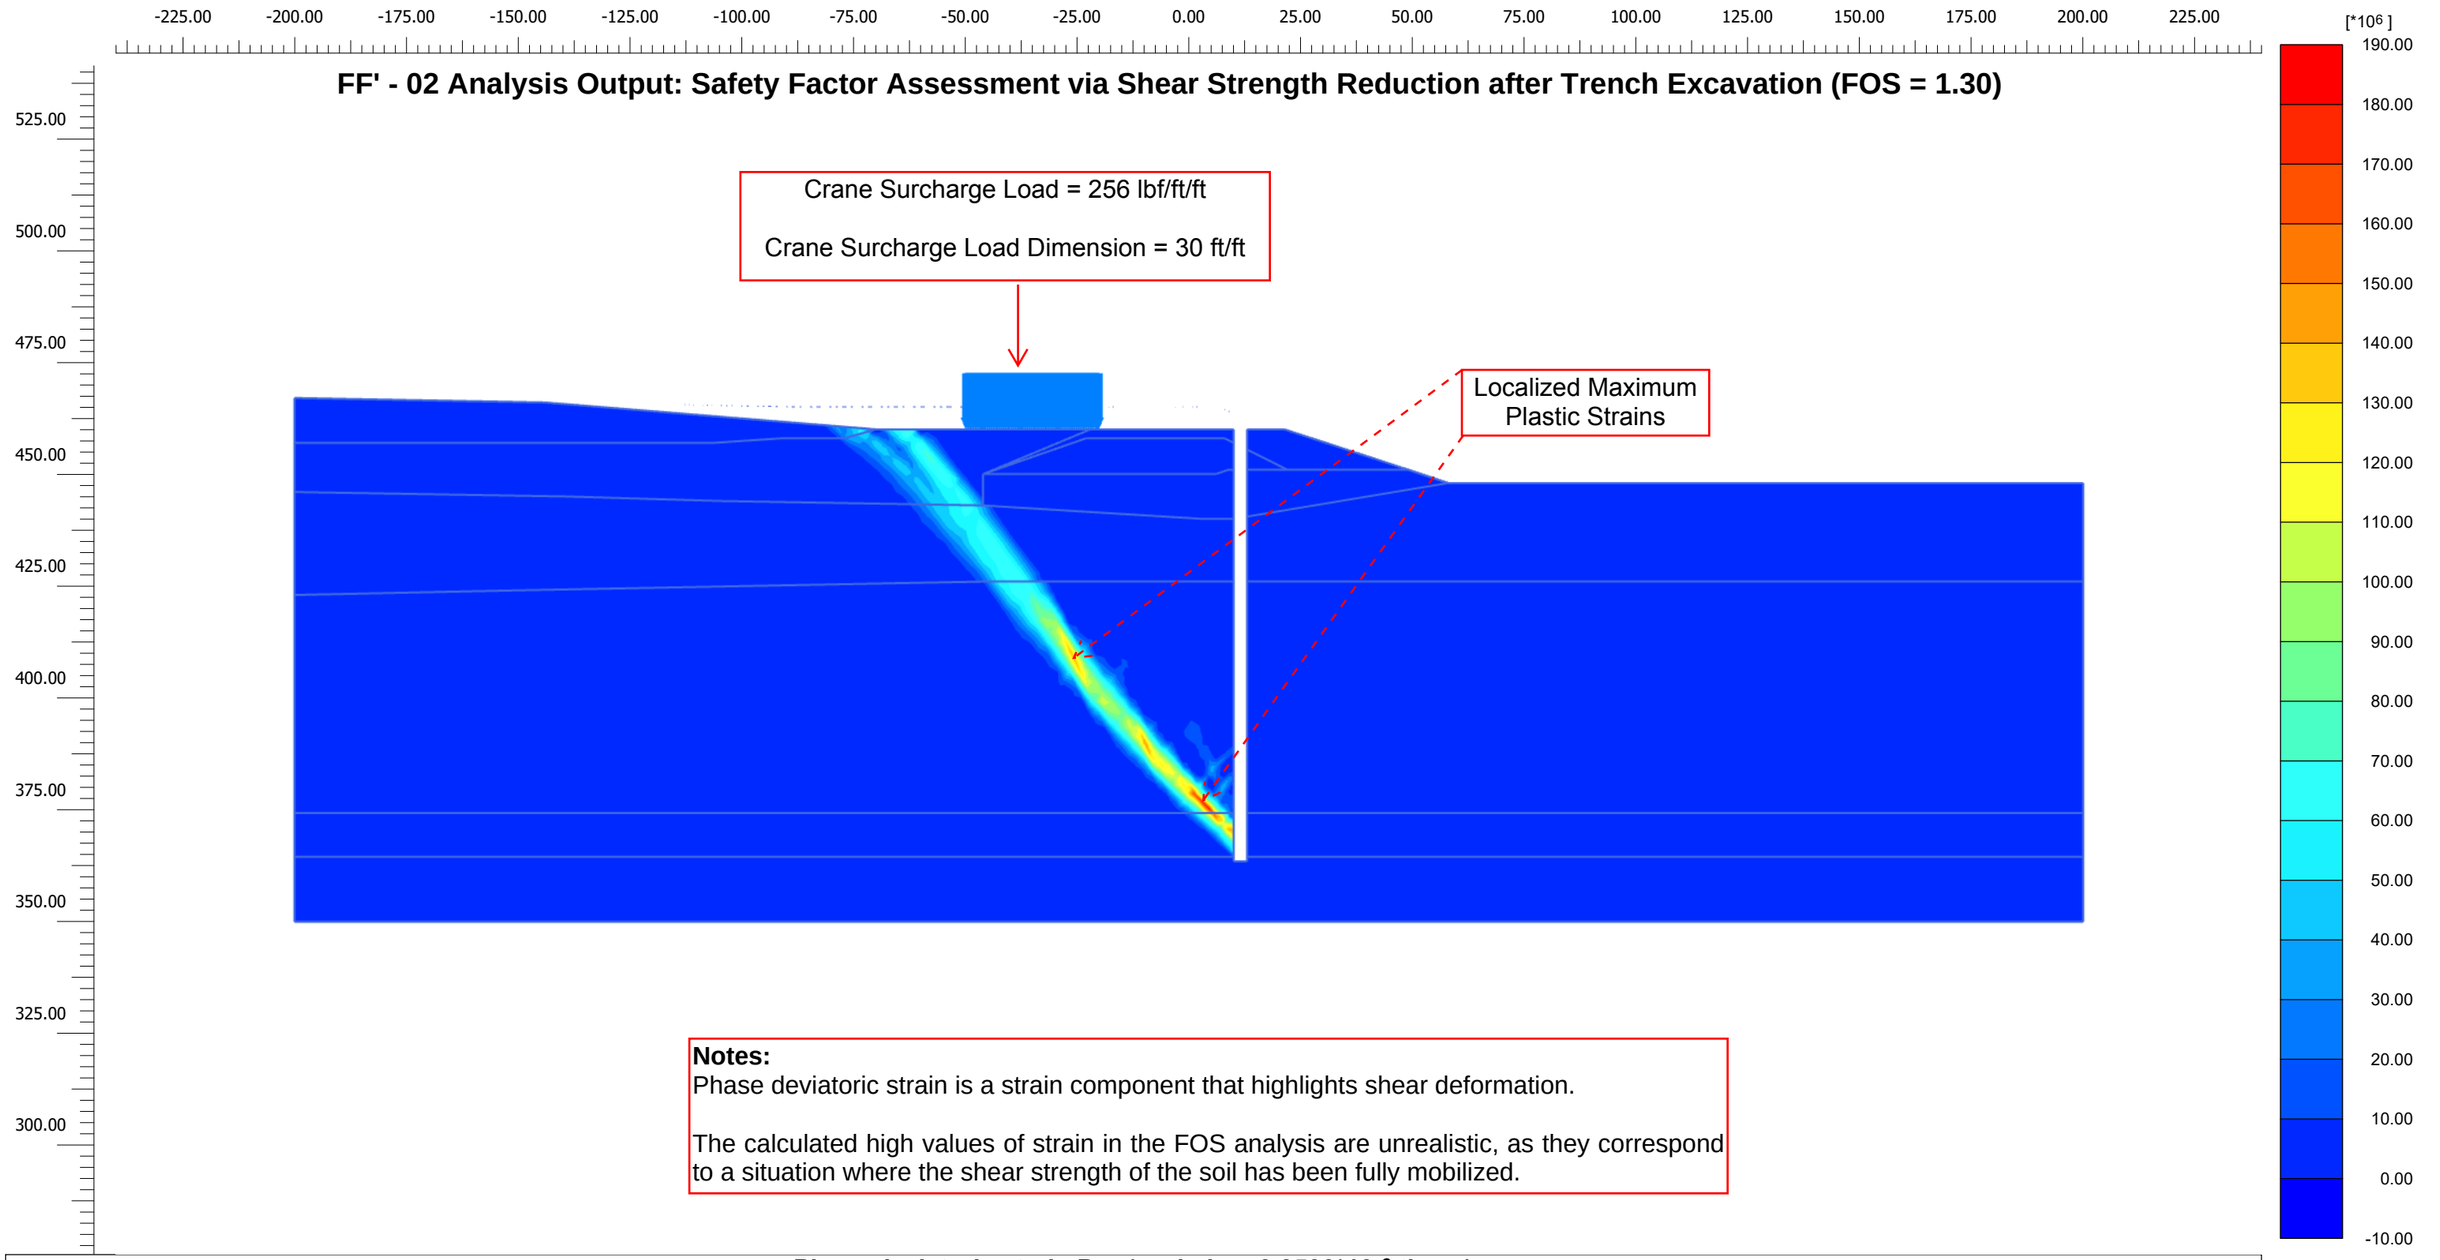
Phase deviatoric strain $P\gamma_s$ (scaled up $0.500*10^{-9}$ times)

Maximum value = $32.58*10^{9}$ (Element 723 at Node 5399)

Minimum value = $0.03550*10^{-6}$ (Element 2292 at Node 19603)

RAMBOLL	*Project description* Hennepin West Ash Pond System Deep Cutoff Wall		*Date* 4/11/2025
	Project filename Cross Section F-F'	*Step* 2199	*Company* Ramboll Americas Engineering Solutions

FF' - 02 Analysis Output: Safety Factor Assessment via Shear Strength Reduction after Trench Excavation (FOS = 1.30)



Notes:
Phase deviatoric strain is a strain component that highlights shear deformation.

The calculated high values of strain in the FOS analysis are unrealistic, as they correspond to a situation where the shear strength of the soil has been fully mobilized.

Phase deviatoric strain $P\gamma_s$ (scaled up $0.0500*10^{-6}$ times)

Maximum value = $180.1*10^{6}$ (Element 2026 at Node 13151)

Minimum value = $2.093*10^{-9}$ (Element 2292 at Node 19612)

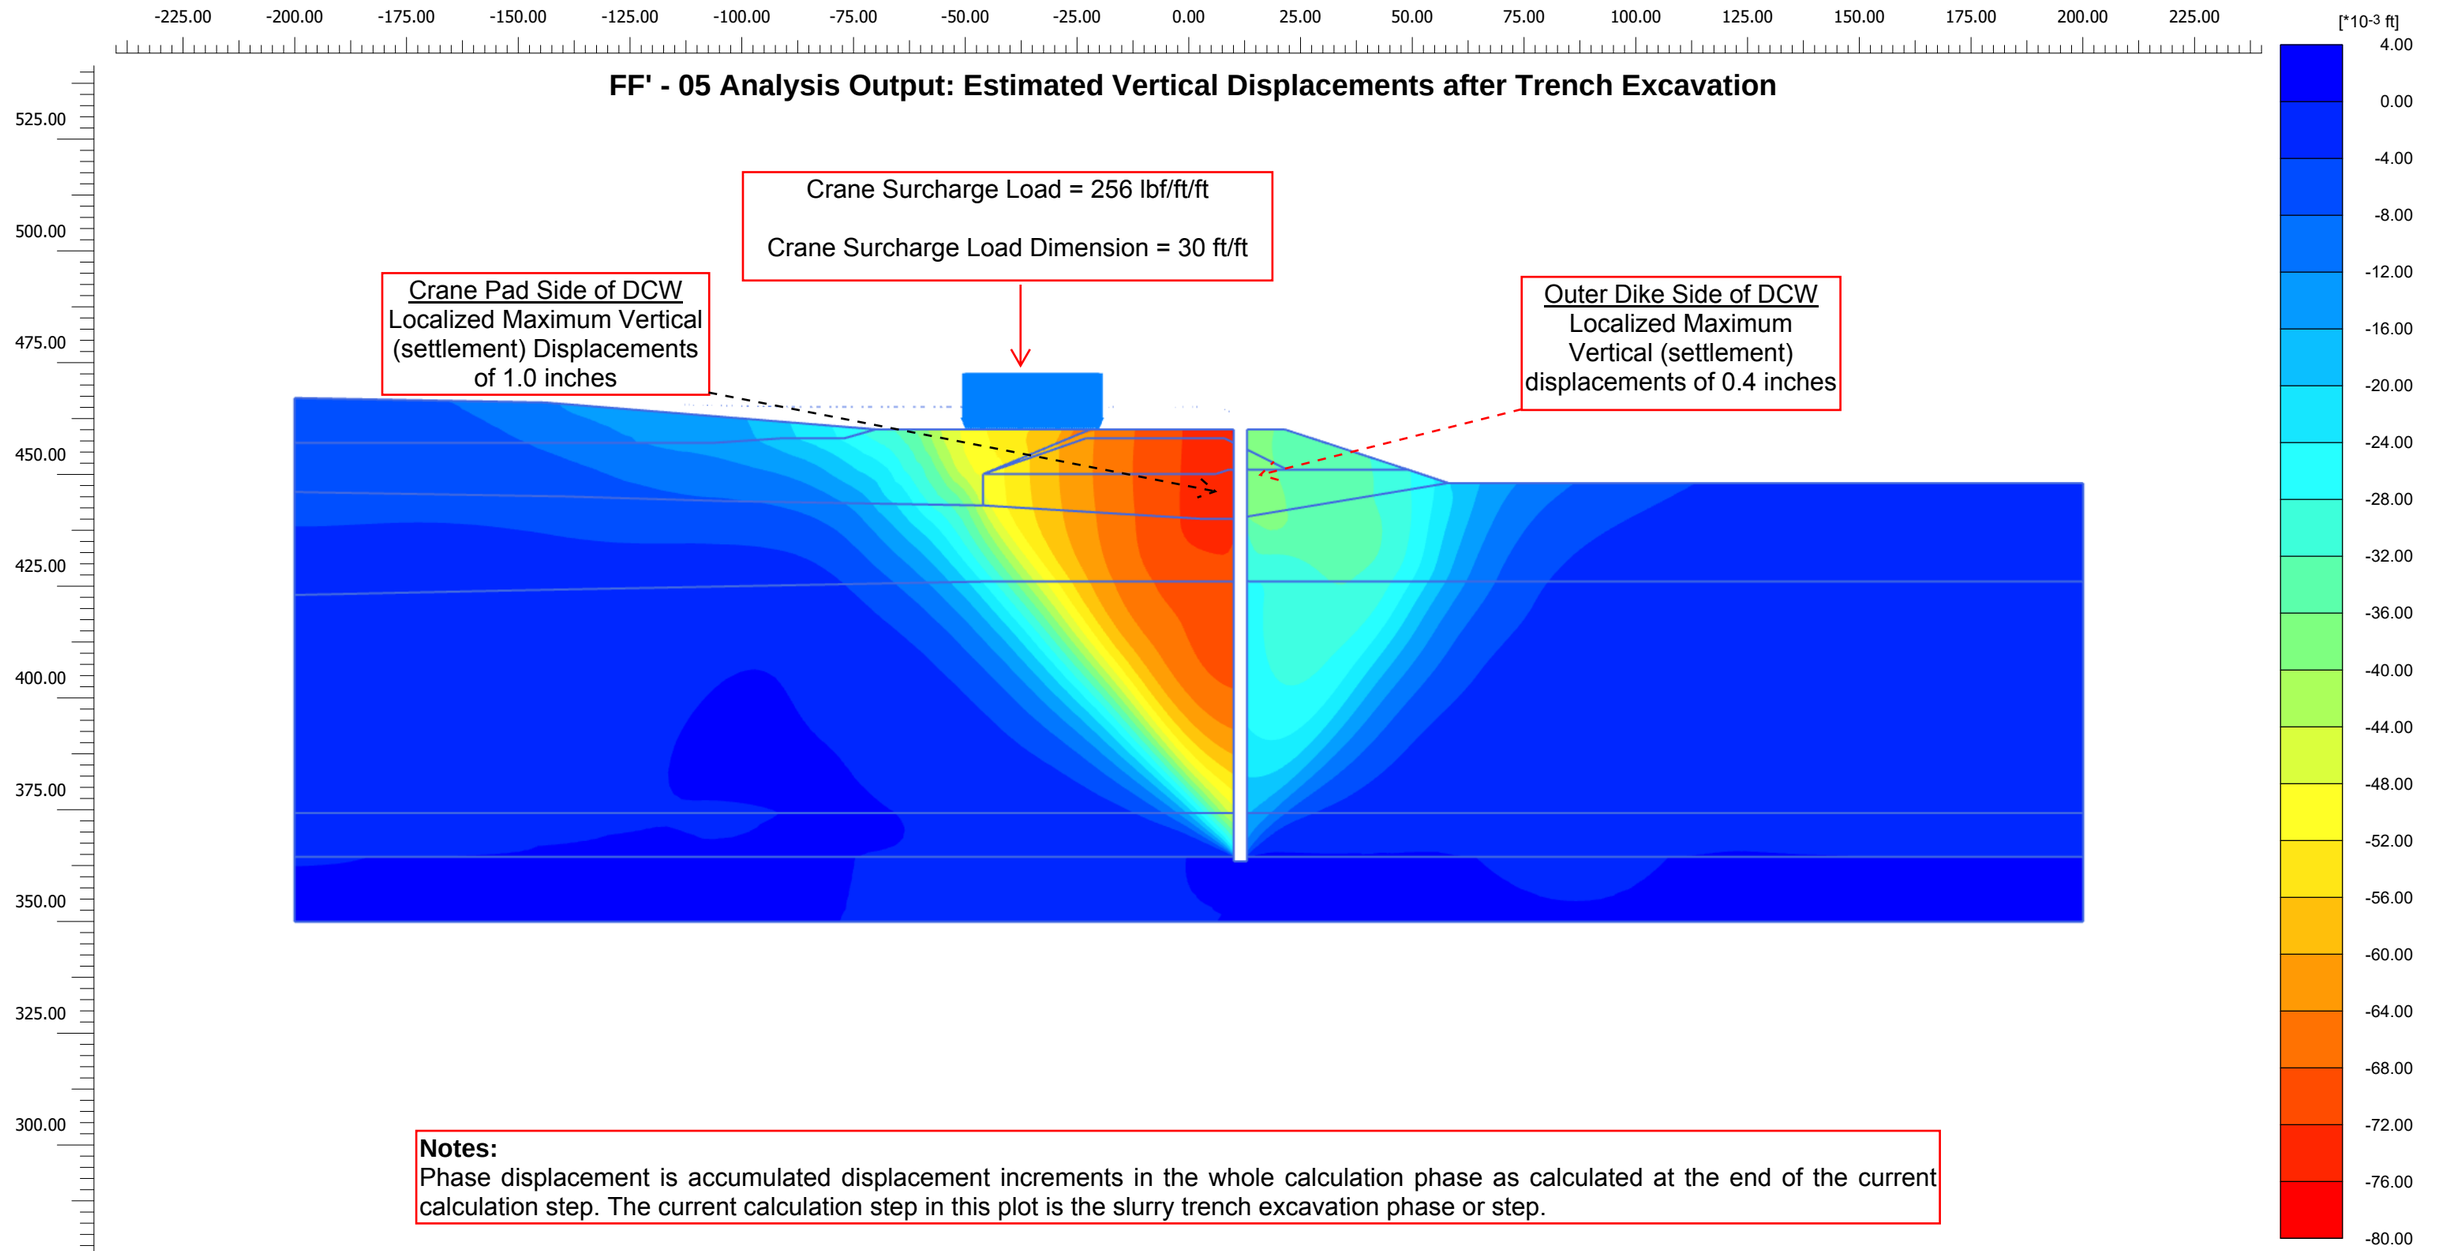
Output Version 21.1.0.479

FF' - 05 Analysis Output: Estimated Vertical Displacements after Trench Excavation



Notes:
Phase displacement is accumulated displacement increments in the whole calculation phase as calculated at the end of the current calculation step. The current calculation step in this plot is the slurry trench excavation phase or step.

Phase displacements Pu_y (scaled up 200 times) (Time $18.29*10^3$ day)

Maximum value = $0.1721*10^{-3}$ ft (Element 1876 at Node 8536)

Minimum value = -0.07622 ft (Element 748 at Node 10745)

Notes

1. All information is shown approximately and is for informational purposes.
2. Existing exploration, piezometers, and monitoring well locations are taken from reports prepared by AECOM, CEC, Geosyntec, NRT, and Ramboll from 2016-2025. These reports are included as attachments to the Corrective Action Plan.
3. Pre-closure borings and CPTs were advanced prior to the construction of the final closure of the WAPS. These explorations were advanced from ground surface elevations and through subsurface materials that may have been significantly altered as part of closure construction.
4. Existing conditions topography and the limits of the final cover system were taken from the permit-level remedial design drawings attached to this corrective action plan. Additional reference information for this information is included within those drawings.

1. PURPOSE

This calculation package presents geotechnical calculations performed to support the development of the final closure design for the Old West Ash Pond (OWAP) and Old West Polishing Pond (OWPP) at the Hennepin Power Station (the Site). The analyses provided in this calculation package include:

(i) a summary of subsurface conditions and development of geotechnical design parameters and seismic inputs;

(ii) liquefaction screening analyses;

(iii) global slope stability analyses for static, pseudo-static, and post-earthquake conditions;

(iv) sheet pile wall design for temporary excavation support of the splitter dike between the OWAP and OWPP (Splitter Dike);

(v) seepage analyses to estimate inflows into the OWPP during excavation,

(vi) cover system veneer stability analyses, and

(vii) closure-induced settlement analyses.

2. SUMMARY OF SUBSURFACE INVESTIGATIONS

Subsurface investigation data for the Site is available from the following sources.

AECOM Investigation, 2015 – West Ash Complex

A subsurface investigation was performed by AECOM at the OWAP and OWPP and consisted of field exploration and laboratory testing between October and December of 2015 (AECOM, 2016). The field exploration included 18 hollow-stem auger and mud rotary borings, installation of 3 geotechnical piezometers to monitor groundwater levels, and 14 cone penetration test (CPT) soundings. Geotechnical explorations were located at the dike crest, dike toe, and within the ponds. Two borings were performed at the toe of the dike immediately north of the OWAP and OWPP, from barges within the Illinois River.

Boring depths ranged from 21.5 to 76.5 feet below ground surface (bgs). Soil samples were collected from each of the borings for laboratory testing. Disturbed soil samples were obtained with a split-spoon sampler during Standard Penetration Testing (SPT) and relatively undisturbed samples were collected using three-inch diameter steel Shelby tubes.

CPT soundings were performed with shear wave velocity measurements and pore pressure dissipation testing. CPT depths ranged from 5.7 to 88.9 feet bgs.

The laboratory testing program included the following tests:

Index Tests:

- Moisture content (ASTM D2216);
- Dry unit weight;
- Atterberg limits (ASTM D4318); and
- Grain size analyses (ASTM D422).

Strength Tests:

- Unconfined compressive strength (UCS) (ASTM D2166);
- Isotropically Consolidated-Undrained (CIU) (ASTM D4767);
- Drained direct shear (ASTM D3080);

Permeability Tests:

- Hydraulic Conductivity Testing (ASTM D5084).

Corrosion Tests:

- Soil Corrosivity Indication Series Testing (ASTM G51 / ASTM G57 / DIPRA)

CEC Investigation, 2016 – Old West Polishing Pond

Civil and Environmental Consultants (CEC) performed an investigation of the thickness of CCR within the OWPP in March of 2016 (CEC, 2016). The investigation consisted of nine hand-advanced Piston sampler borings, which were collected from a pontoon boat within the OWPP. Boring depths ranged from 6.2 to 8.5 feet. Each boring was advanced through CCR and into the underlying native soils. No laboratory testing was performed.

CEC Investigation, 2017 – Old West Ash Pond

CEC performed a subsurface investigation in March 2017 at the OWAP and Splitter Dike (CEC, 2017). The investigation was performed to evaluate the thickness and extents of CCR within the OWAP. The investigation consisted of 20 hollow-stem auger borings with SPT and split-spoon and Shelby tube sampling. Piezometers were installed in six of the borings. Boring depths ranged from 13 to 30 feet bgs. Each boring was advanced through CCR and into the underlying native soils. No laboratory testing was performed.

Geosyntec Investigation, 2017 – Old West Ash Pond and Old West Polishing Pond

Geosyntec performed a subsurface investigation in December 2017 at the OWAP, OWPP, and splitter dike (Geosyntec, 2018). The investigation was performed to: (i) evaluate the need for dewatering of CCR during closure construction, (ii) gather data on the compressibility of CCR and alluvial foundation soils for settlement analyses, (iii) evaluate geotechnical conditions along the approximate alignment of the proposed sheet pile wall, and (iv) collect information on the depth to and type of bedrock at the site. The investigation consisted of eight piezometers, nine test pits, and two borings on the OWAP; two piezometers along the OWPP perimeter dikes; and four borings along the proposed sheet pile wall alignment. Samples of soil and CCR were collected from select borings and piezometers for laboratory testing. Borings and piezometers were advanced to depths between 10.1 and 55.5 feet; test pits were advanced to depths between 5.0 and 10.5 feet.

The laboratory testing program included the following tests:

Index Tests:

- Moisture content (ASTM D2216);
- Dry unit weight;
- Atterberg limits (ASTM D4318);
- Grain size analyses (ASTM D422); and
- Specific gravity (ASTM D854).

Strength Tests:

- Unconsolidated-undrained triaxial (UU) (ASTM D2850);

Permeability Tests:

- Flexible wall hydraulic Conductivity Testing (ASTM D5084)

Compressibility Tests:

- Incremental one-dimensional consolidation (ASTM D2435)

3. SUMMARY OF SUBSURFACE CONDITIONS

In general, the soils encountered at the OWAP and OWPP included;

(i) CCR (predominantly fly ash with some bottom ash) within the ponds;
(ii) Sand and Gravel Dike Fill, comprising the upper-most portions of the perimeter dikes (typically 10 to 15 ft thick, but variable across the site);
(iii) Silt and Clay Dike Fill, comprising the lower portions of the perimeter dikes,
(iv) Silt and Clay Alluvium, beneath the dikes and CCR;
(v) Sand and Gravel Alluvium, beneath the Silt and Clay Alluvium in most areas, although sometimes directly under the CCR and perimeter dikes where the Silt and Clay Alluvium is not present.
(vi) Organic Sediments were also present in the Illinois River riverbed, directly overlying the Silt and Clay Alluvium soils.

Each subsurface material is discussed in the following sub-sections.

CCR

CCR at the OWAP and OWPP predominantly consisted of wet-sluiced material within the interior of the pond. The material size was generally classified as silt, sandy silt, or silty sand; this indicates that the material is predominantly fly ash but also contains zones of bottom ash. The consistency of the material, based on uncorrected field SPT blowcounts, ranged from very loose to dense within the interior of the pond. CCR was found to underlie the splitter dike between the Old West Ash Pond and Old West Polishing Pond; this indicates that the dike was constructed over sluiced CCR as stated in historic construction documents (AECOM, 2016b).

A limited amount of CCR intermingled with Silt and Clay Dike Fill was encountered in 2015 AECOM boring HEN-B012 (AECOM, 2016), drilled in the southwest dike crest of the Old West Ash Pond. The material was encountered between 15 and 25 feet in depth

and was described as a hard, sandy silt with ash, and had an SPT N-value of 47. This indicates that the material was likely placed as structural dike fill and means that it is unlikely that the material is comprised of sluiced CCR. CCR was not encountered within the perimeter dikes of the Old West Ash Pond in any other borings reviewed by Geosyntec (AECOM, 2015; CEC, 2017; and Geosyntec, 2018).

Sand and Gravel Dike Fill [SGDF]

The SGDF at the OWAP and OWPP consisted of compacted granular fill. The fill is present above the Silt and Clay Dike Fill around the entire perimeter of the OWAP and OWPP, and at the splitter dike, and was placed circa 1988-1989 to raise the crest of the dike from approximately El. 460 ft to El. 465 ft (AECOM, 2016b). The SGDF was generally classified as clayey gravel or clayey sand. The consistency of the material, based on uncorrected field SPT blow counts, was typically medium dense to very dense.

Silt and Clay Dike Fill [SCDF]

The SCDF at the OWAP and OWPP consisted of compacted cohesive dike fill and underlies the SCDF around the entire perimeter embankment, and at the splitter dike. The material constitutes the original OWAP and OWPP embankment constructed in 1951 and 1952 and the splitter dike between the OWPP and OWAP constructed in 1988 to 1989 (AECOM, 2016b). The 1951-1952 and 1988-1989 materials were found to have essentially the same geotechnical characteristics. The SCDF was generally classified as a lean clay, clayey silt, or silt, although some pockets of granular material were also present. The consistency of the material, based on uncorrected field SPT blow counts, was typically medium stiff to stiff.

Silt and Clay Alluvium [SCA]

The SCA at the OWAP and OWPP consisted of native, normally-consolidated alluvial deposits and underlie the dike materials and most of the pond. The SCA is not present at the northeast corner of the OWAP, where the CCR lies directly on top of the Sand and Gravel Alluvium. The Silt and Clay Alluvium was generally classified as a lean clay, clayey silt, or silt, although some pockets of granular material were also present. The consistency of the materials, based on uncorrected field SPT blow counts, was typically medium stiff.

Sand and Gravel Alluvium [SGA]

The SGA at the OWAP and OWPP consisted of native alluvial and glacial outwash deposits and underlaid the entirety of the Site. The material was generally classified as a silty gravel, clayey gravel, well-graded gravel, or a silty sand, although some pockets of cohesive material were also present. The consistency of the SGA, based on uncorrected field SPT blow counts, was typically medium dense to dense.

Organic Sediments

Organic sediments were encountered overlying the alluvial materials in barge-based borings drilled within the Illinois River, and consisted of recent, normally-consolidated river sediments. The material was generally classified as an organic clay with some pockets of silty sand. The consistency of the material, based on uncorrected field SPT blow counts, was typically very soft.

4. DESIGN GEOTECHNICAL STRENGTH AND UNIT WEIGHT PARAMETERS

Design geotechnical strength and unit weight parameters for each subsurface material were selected using available laboratory data, CPT sounding information, published correlations, and engineering judgment. Design geotechnical parameters are summarized in Table 1, and the process used to select the design geotechnical parameters is described in the following sub-sections. Design hydraulic parameters are discussed in Section 8.

CCR

The design total unit weight of CCR was selected as 99 pcf based on laboratory measurements (Figure 1). It should be noted that some of the CCR specimens that were subjected to unit weight and CIU triaxial tests were observed to be mixed CCR and soil. These specimens are indicated using a different symbol on Figures 1, 2, and 3.

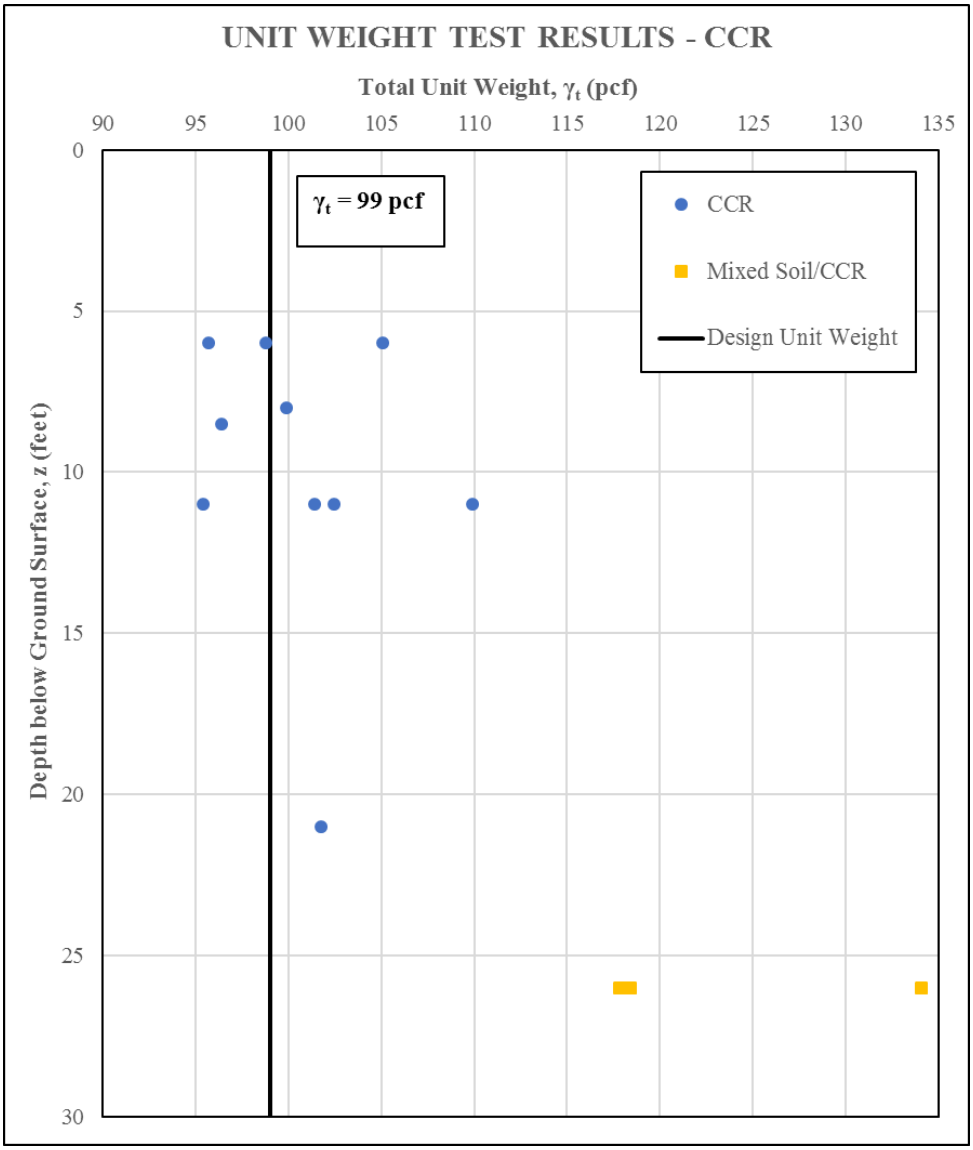

Figure 1. Design Unit Weight of the CCR

The design drained strength of the CCR material was selected as a friction angle of 33 degrees with no cohesion based on results of CIU triaxial tests (Figure 2). Triaxial test specimen failure was defined as peak obliquity, limited to 10% maximum axial strain.

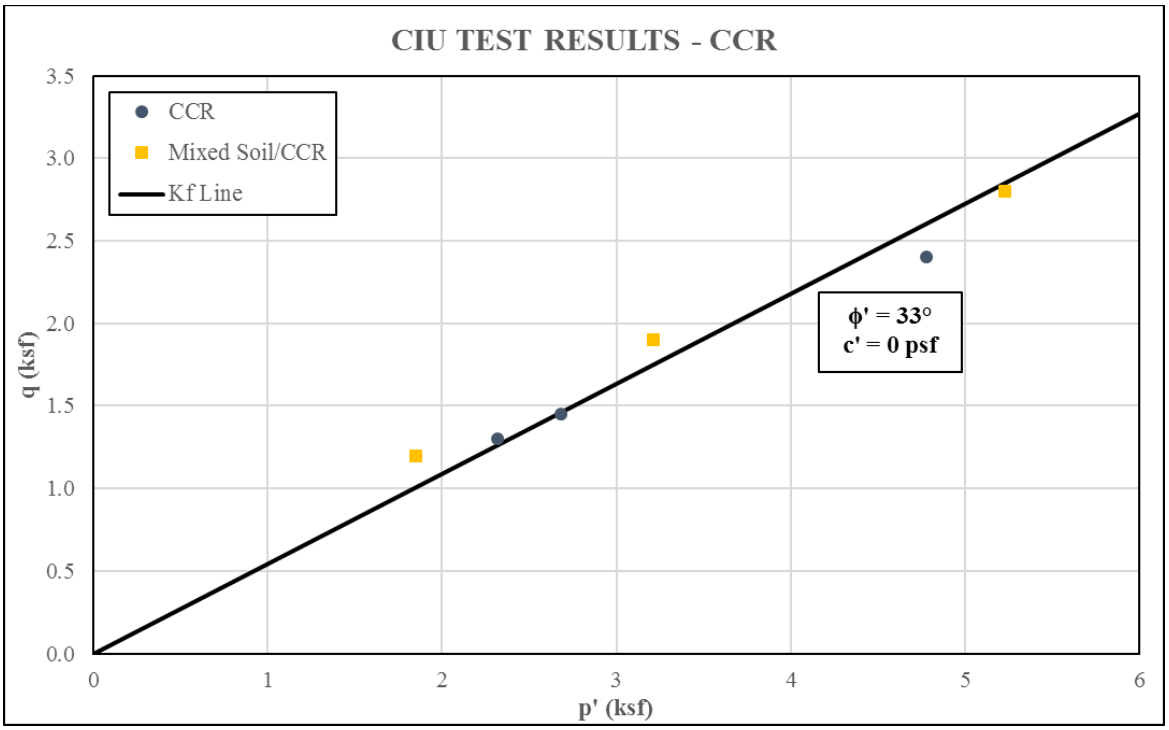

Figure 2. Design Drained Strength of the CCR

The peak undrained strength of the CCR materials was modeled using a ratio of undrained shear strength on the failure plane at failure to vertical consolidation stress on the failure plane prior to shear (i.e., $\frac{\tau_{ff}}{\sigma'_{fc}}$ or a c/p' ratio). A lower-bound ratio of 0.42 was selected based on CIU triaxial test measurements (Figure 3). Failure of CIU specimens was again defined as peak obliquity, limited to 10% strain. *In-situ* vertical effective stress ranges for CCR within the OWAP range from 0 to 2.5 ksf, and the selected ratio of 0.42 represents a lower-bound shear strength within this range of stresses.

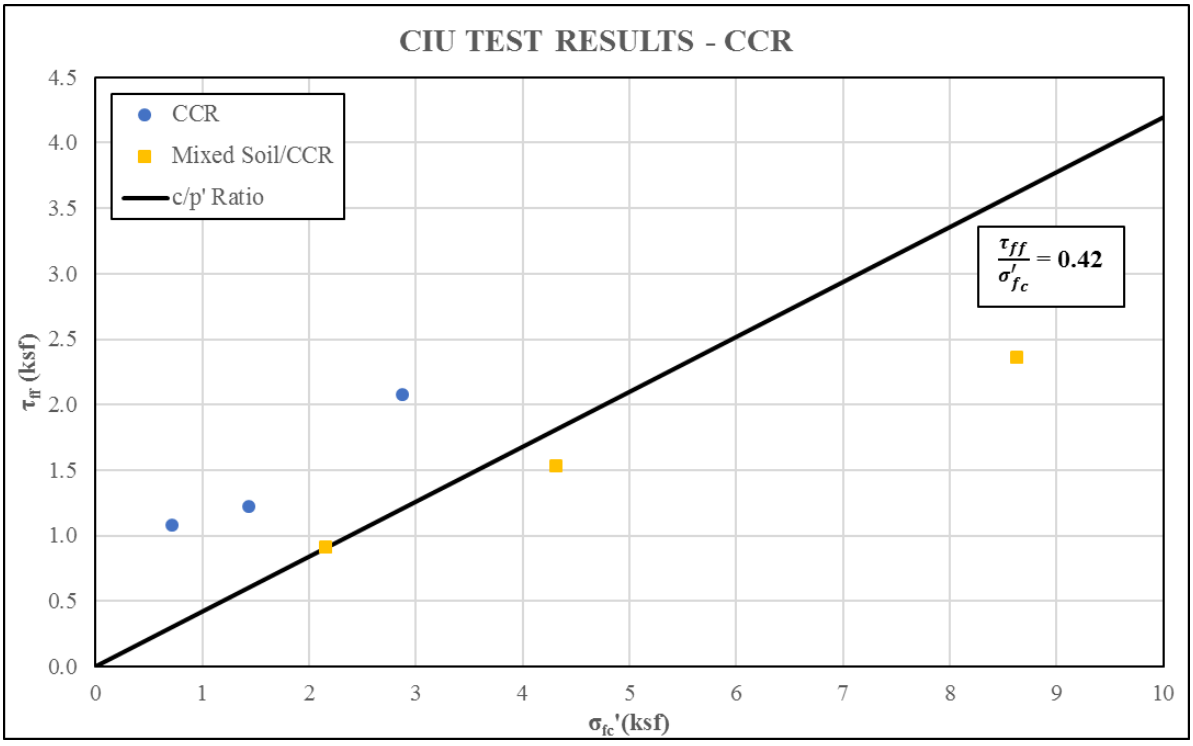

Figure 3. Design Undrained Strength of the CCR

Silt and Clay Alluvium

The design total unit weight of the Silt and Clay Alluvium was selected as 111 pcf based on laboratory measurements (Figure 4). This corresponds to a mean unit weight for the entire site.

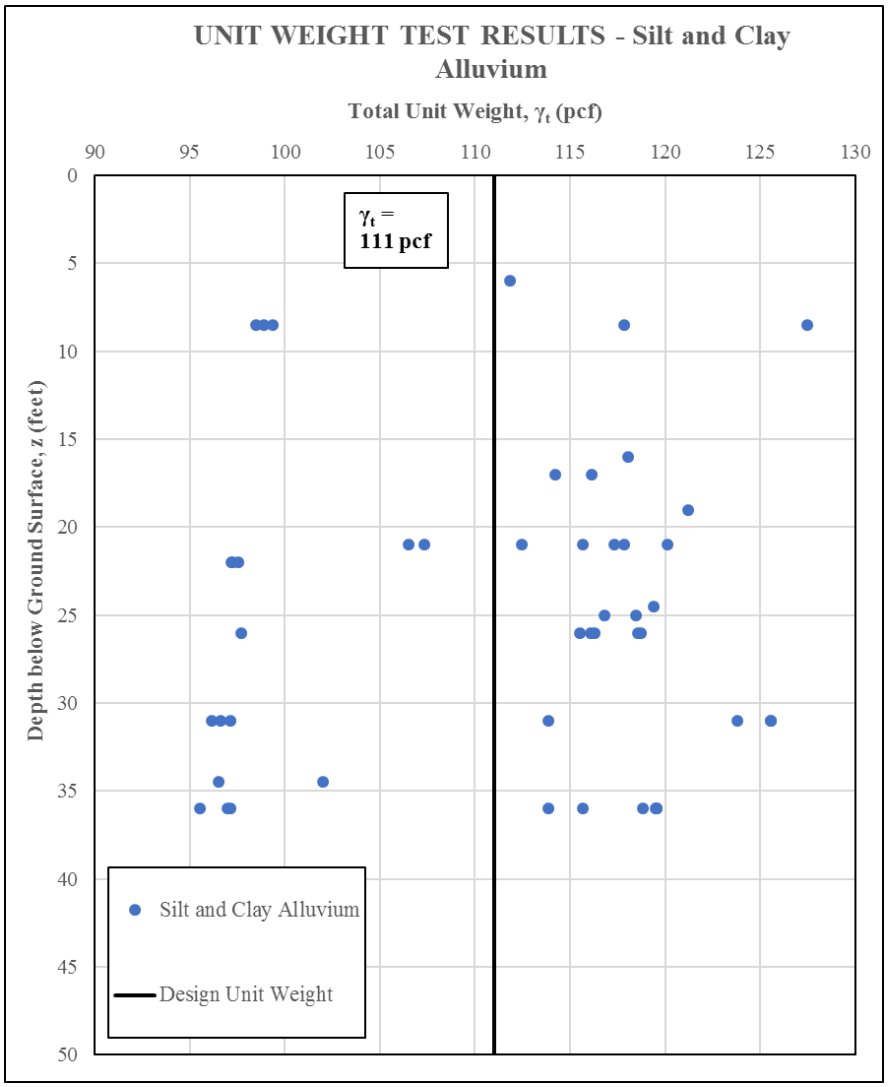

Figure 4. Design Unit Weight of the Silt and Clay Alluvium

The drained shear strength of the Silt and Clay Alluvium was selected based on CIU triaxial and direct shear tests. Failure for CIU specimens was defined as peak obliquity, limited to 10% axial strain, while failure for direct shear specimens was defined as peak shear stress, limited to 10% shear strain. From the CIU triaxial data and direct shear data, design friction angles of 30 degrees and 25 degrees were selected, respectively, as shown

in Figures 5 and 6. From both the CIU and direct shear data a cohesion of 75 psf was selected for design. Based on these test results it is assumed that there is strength anisotropy, which is common in fine-grained alluvial deposits. The strength anisotropy was modeled within the slope stability analysis using an anisotropic strength function, which varies the friction angle as a function of the slip surface base angle. Slip surface angles of 1 to 90 degrees (e.g. triaxial compression) were assigned a friction angle of 30 degrees while slip surface angles of 0 to -90 degrees (e.g. direct shear and triaxial extension) were assigned a friction angle of 25 degrees. A constant cohesion of 75 psf was assumed for all slip surface base angles.

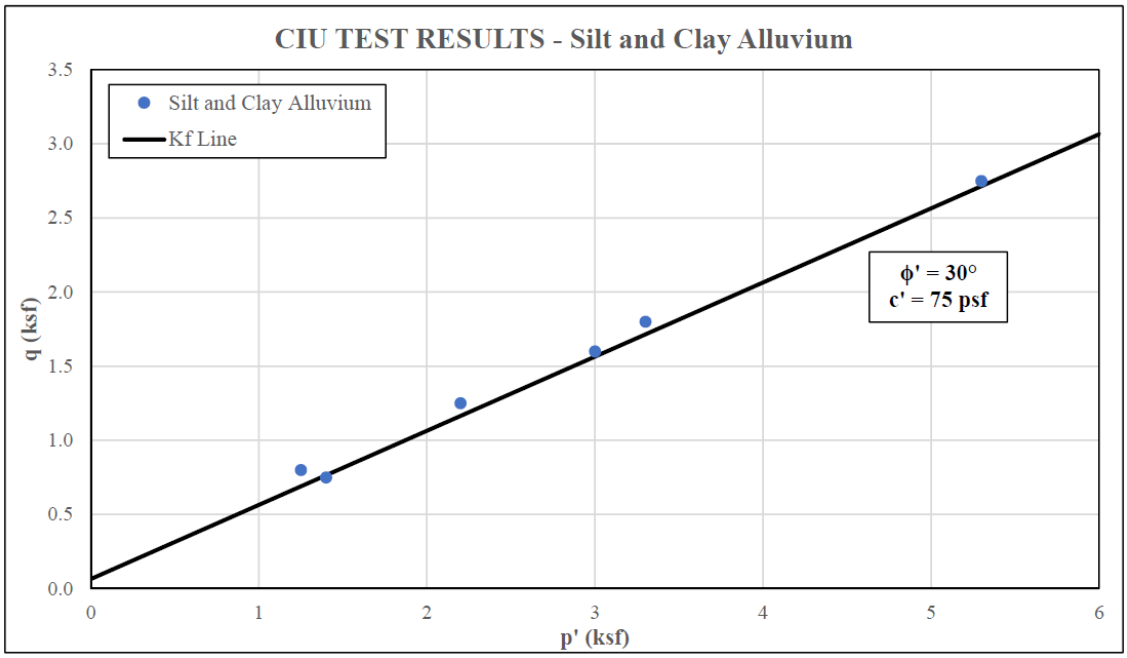

Figure 5. CIU Triaxial Design Drained Strength of the Silt and Clay Alluvium

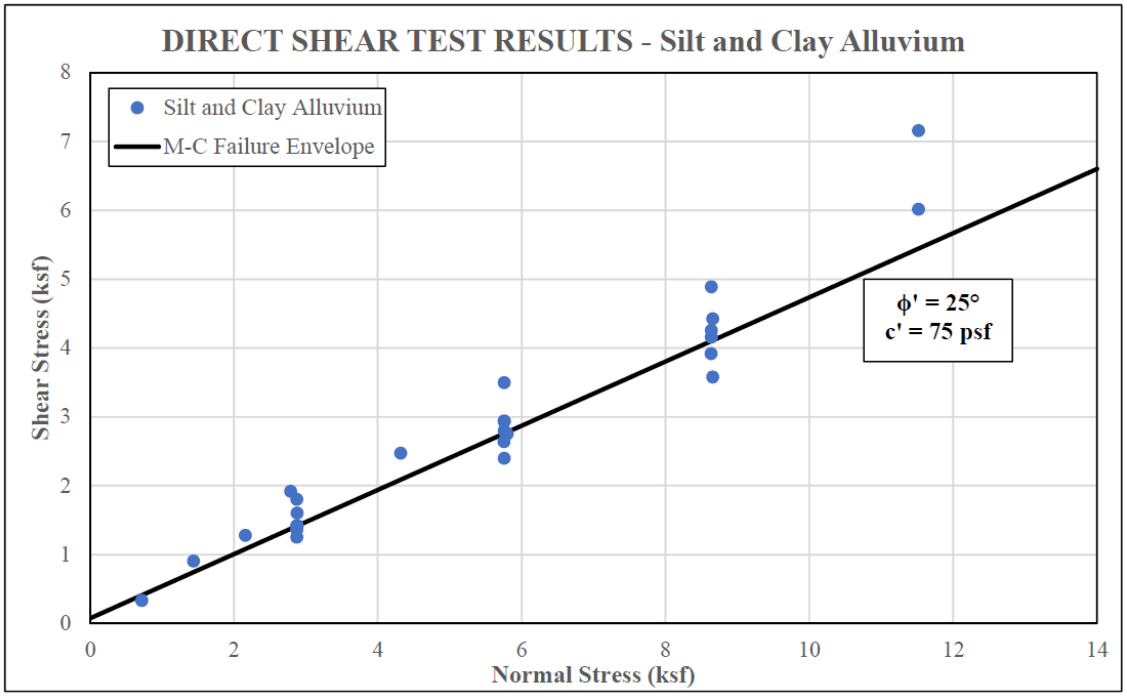

Figure 6. Direct Shear Design Drained Strength of the Silt and Clay Alluvium

The design undrained shear strength of the Silt and Clay Alluvium was selected using a function of undrained shear strength vs. depth below grade, as shown in Table 1 and Figure 7. The strength data were found to correlate better with depth below existing grade rather than with sample elevation and were therefore plotted as such. Undrained shear strength data were taken from unconfined compressive strength (UCS) and unconsolidated-undrained triaxial tests (AECOM, 2016 and Geosyntec, 2018) and correlation with CPT data. The CPT correlation follows NCHRP (2007) and used a N_{kT} value of 17 which provided a reasonable agreement with the UCS data. The design undrained shear strengths are indicative of a normally-consolidated alluvial clay, as the shear strength was found to increase with depth and approximately follows a c/p' ratio of 0.3.

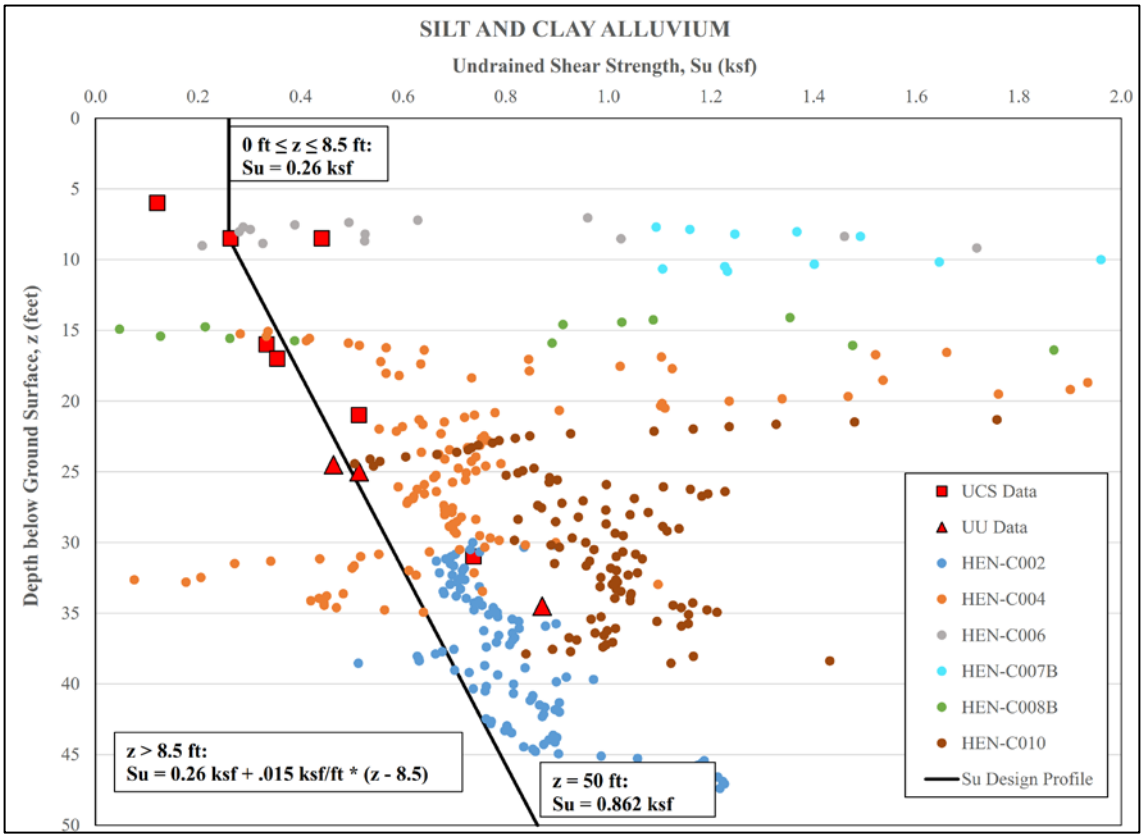

Figure 8. Design Undrained Strength of the Silt and Clay Alluvium

Silt and Clay Dike Fill

The Silt and Clay Dike Fill was assigned the same design unit weight and drained strength parameters as the Silt and Clay Alluvium, as drained shear strength test data is not available for this material, and it is likely comprised of Silt and Clay Alluvium that was excavated from the footprint of the ponds and compacted to form the dikes. The undrained strength of the Silt and Clay Dike Fill was estimated to be a constant value of 1,000 psf based on unconfined compressive strength tests and CPT data (Figure 9), following the same methodology used for the Silt and Clay Alluvium. The apparent scatter in the CPT data in Figure 9 is primarily due to the presence of gravel win the Silt and Clay Dike Fill; these high correlated undrained shear strengths were therefore not used for design.

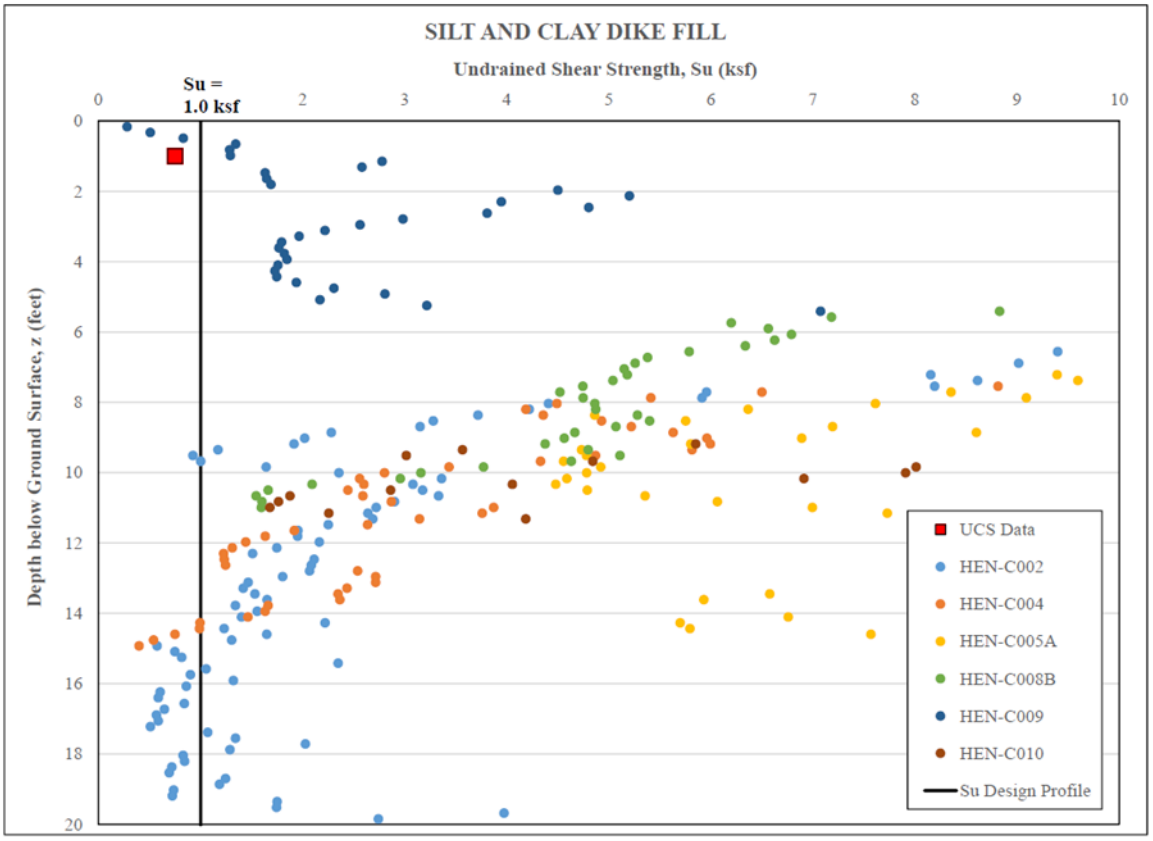

Figure 9. Design Undrained Strength of the Silt and Clay Dike Fill

Sand and Gravel Dike Fill

The Sand and Gravel Dike Fill was assigned a unit weight of 120 pcf (Figure 10) based on correlation with CPT data following NCHRP (2007).

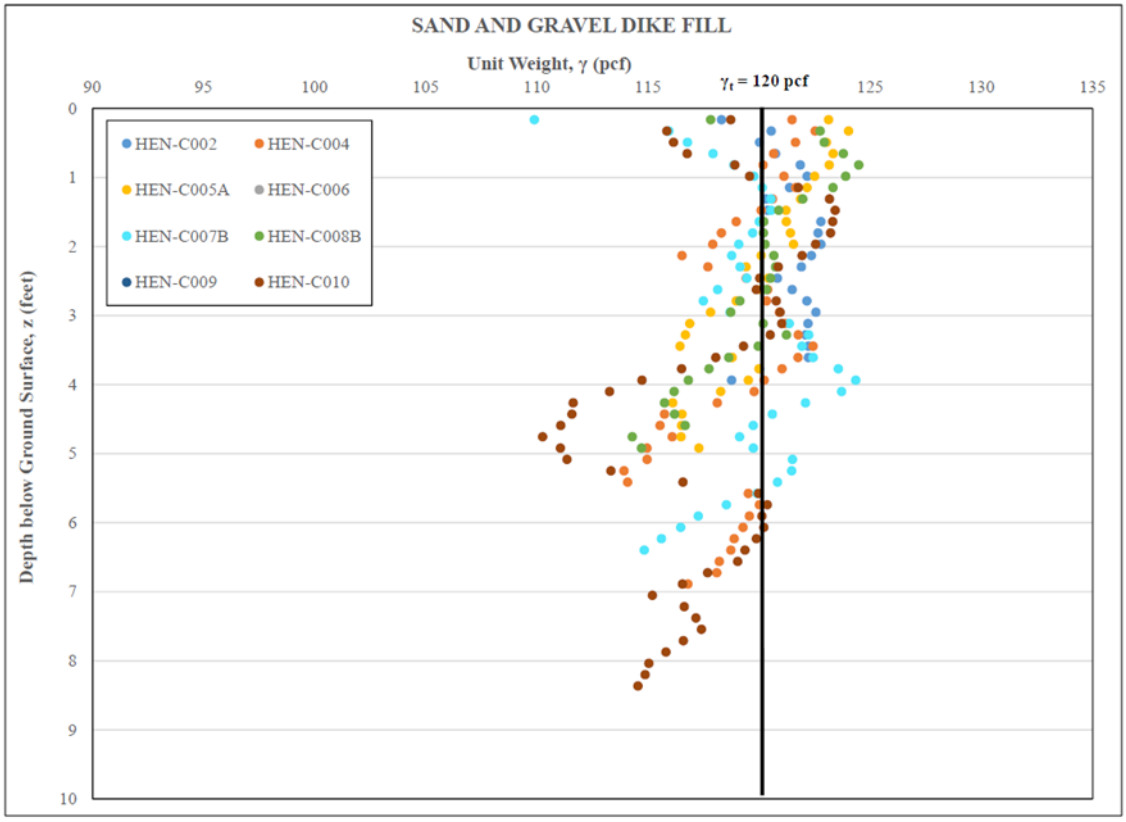

Figure 10. Design Unit Weight of the Sand and Gravel Dike Fill

The Sand and Gravel Dike Fill was assigned a 38-degree friction angle with no cohesion (Figure 11) based on correlation with CPT data following Kulhawy and Mayne (1990). Although the CPT correlations indicated friction angles above 38 degrees, the design friction angle was limited to 38 degrees based on engineering judgment. The material is assumed to be free-draining and respond in a drained manner to both static and seismic loading conditions.

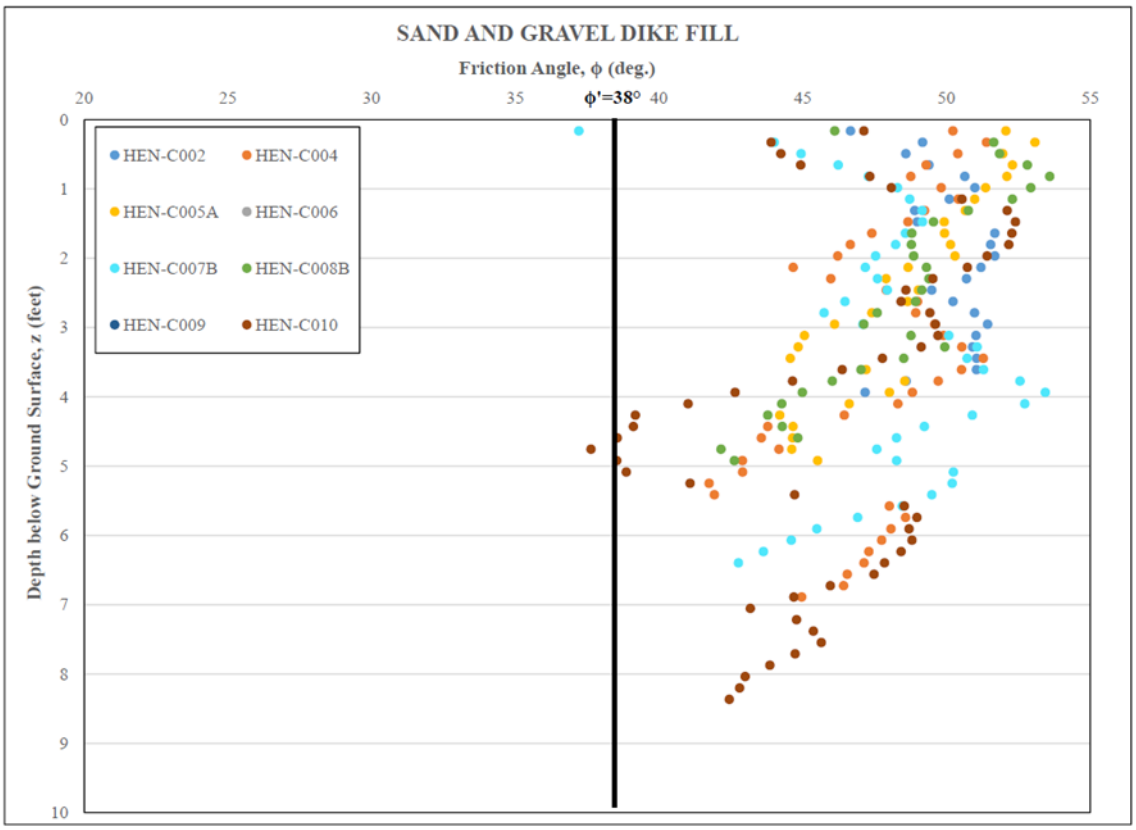

Figure 11. Design Drained Strength of the Sand and Gravel Dike Fill

Sand and Gravel Alluvium

The Sand and Gravel Alluvium was assigned an unsaturated unit weight of 115 pcf above a depth of 20 feet bgs and a saturated unit weight of 125 pcf at 20 feet bgs and deeper based on correlation with CPT data (Figure 12), following the same methodology used for the Sand and Gravel Dike Fill.

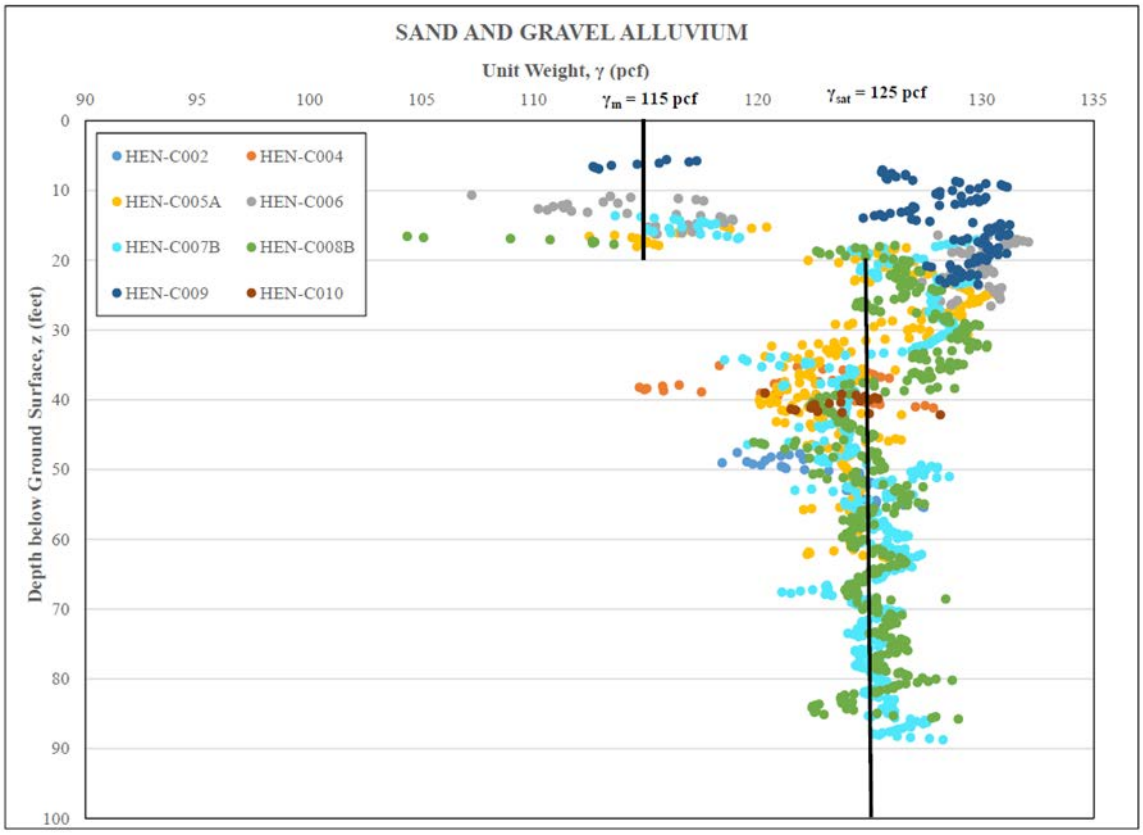

Figure 12. Design Unit Weight of the Sand and Gravel Alluvium

A friction angle of 38 degrees with no cohesion was assigned for the Sand and Gravel Alluvium material based on correlation with CPT data (Figure 13), following the same methodology as the Sand and Gravel Dike Fill. The material was assumed to be free draining and respond in a drained manner to both static and seismic loading conditions.

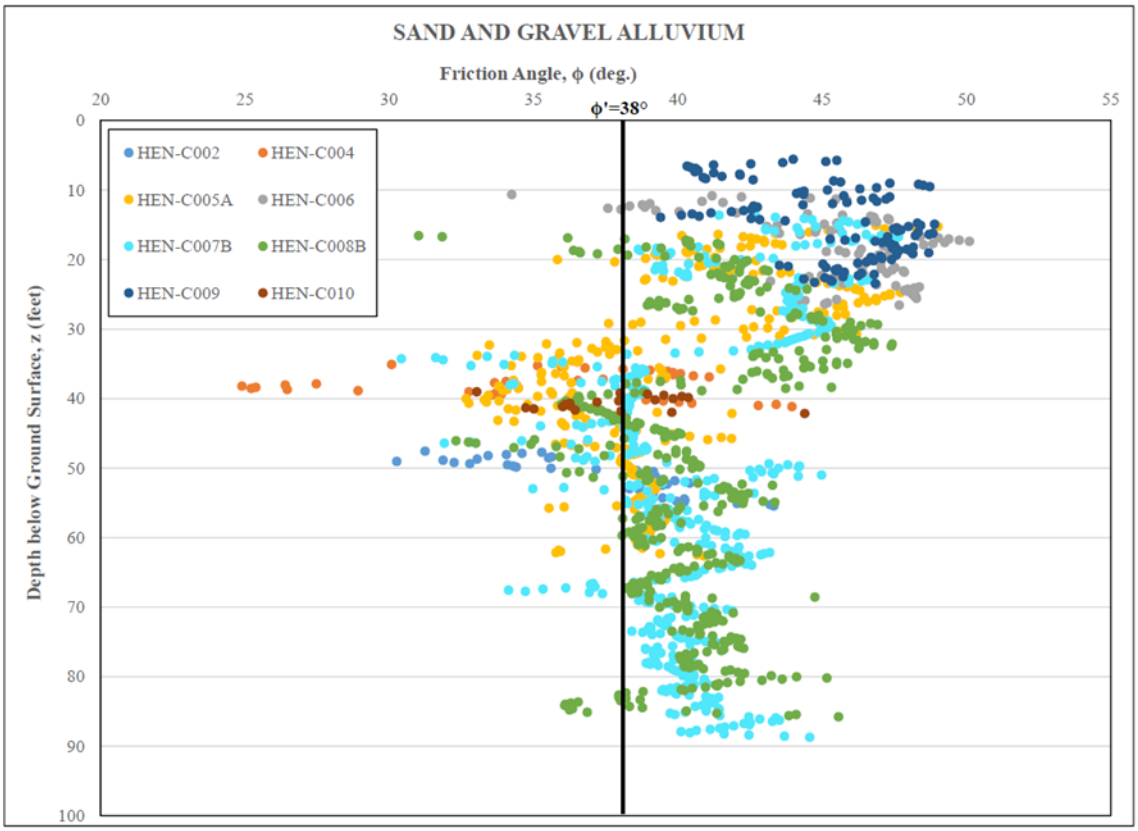

Figure 13. Design Drained Strength of the Sand and Gravel Alluvium

Organic Sediments

The Organic Sediments were assigned a design unit weight of 107 pcf based on the mean value of laboratory measurements (Figure 14).

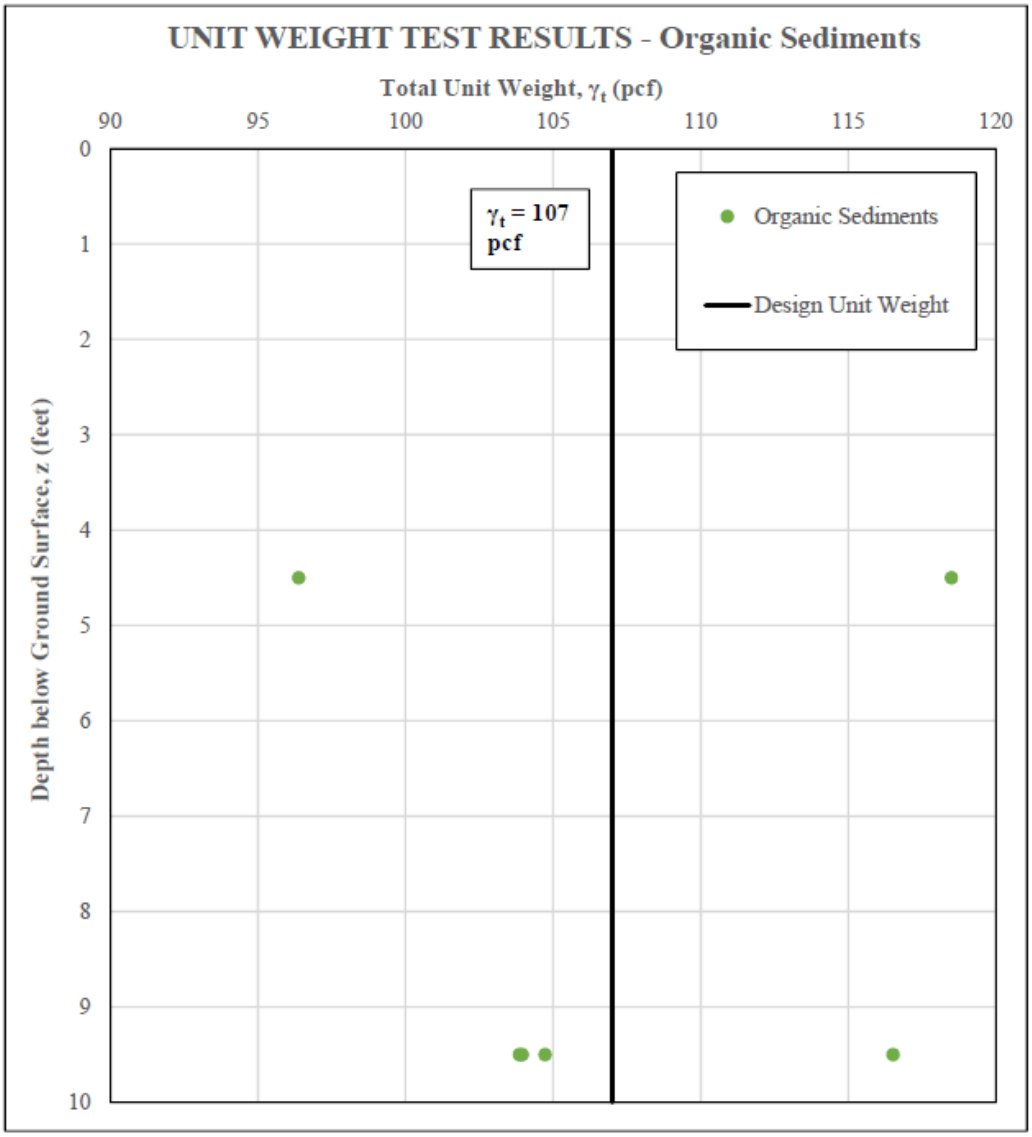

Figure 14. Unit Weight of the Organic Sediments

The design drained shear strength of the organic sediments was selected based on direct shear tests. Based on the direct shear data shown in Figure 15, a design friction angle of 24 degrees with no cohesion was selected for design.

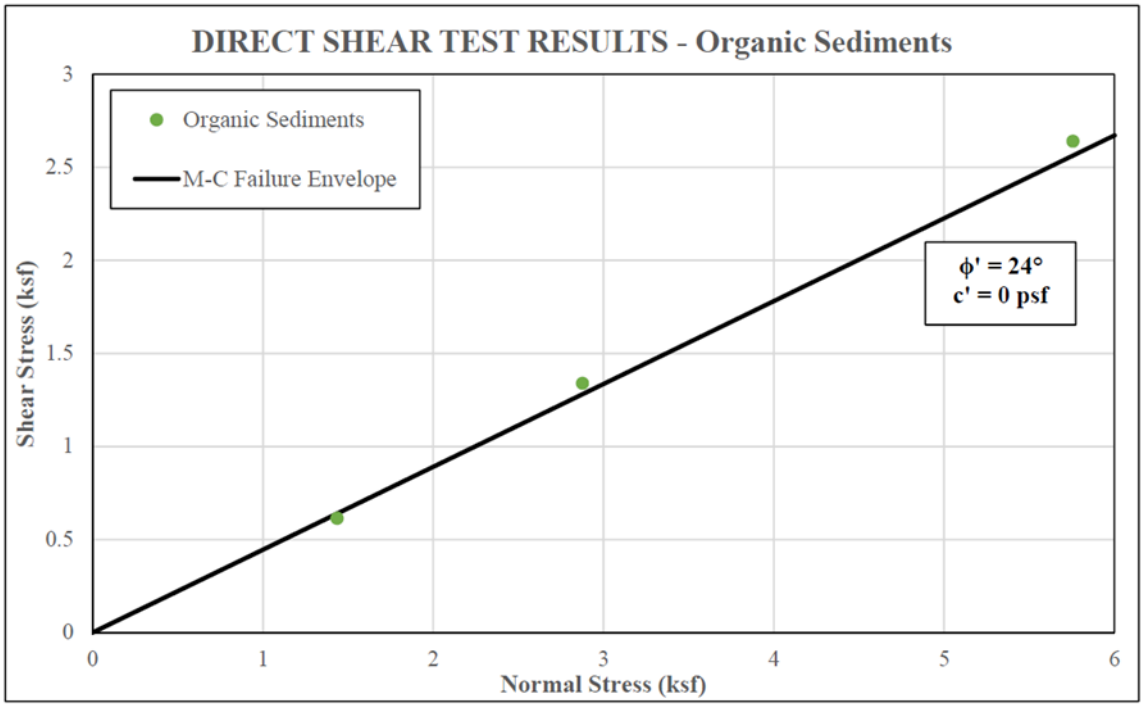

Figure 15. Drained Strength of the Organic Sediments

The design undrained shear strength of the Organic Sediments was selected using a function of undrained shear strength vs. depth below grade, as shown in Table 1 and Figure 16. Undrained shear strength data was taken from unconfined compressive strength tests.

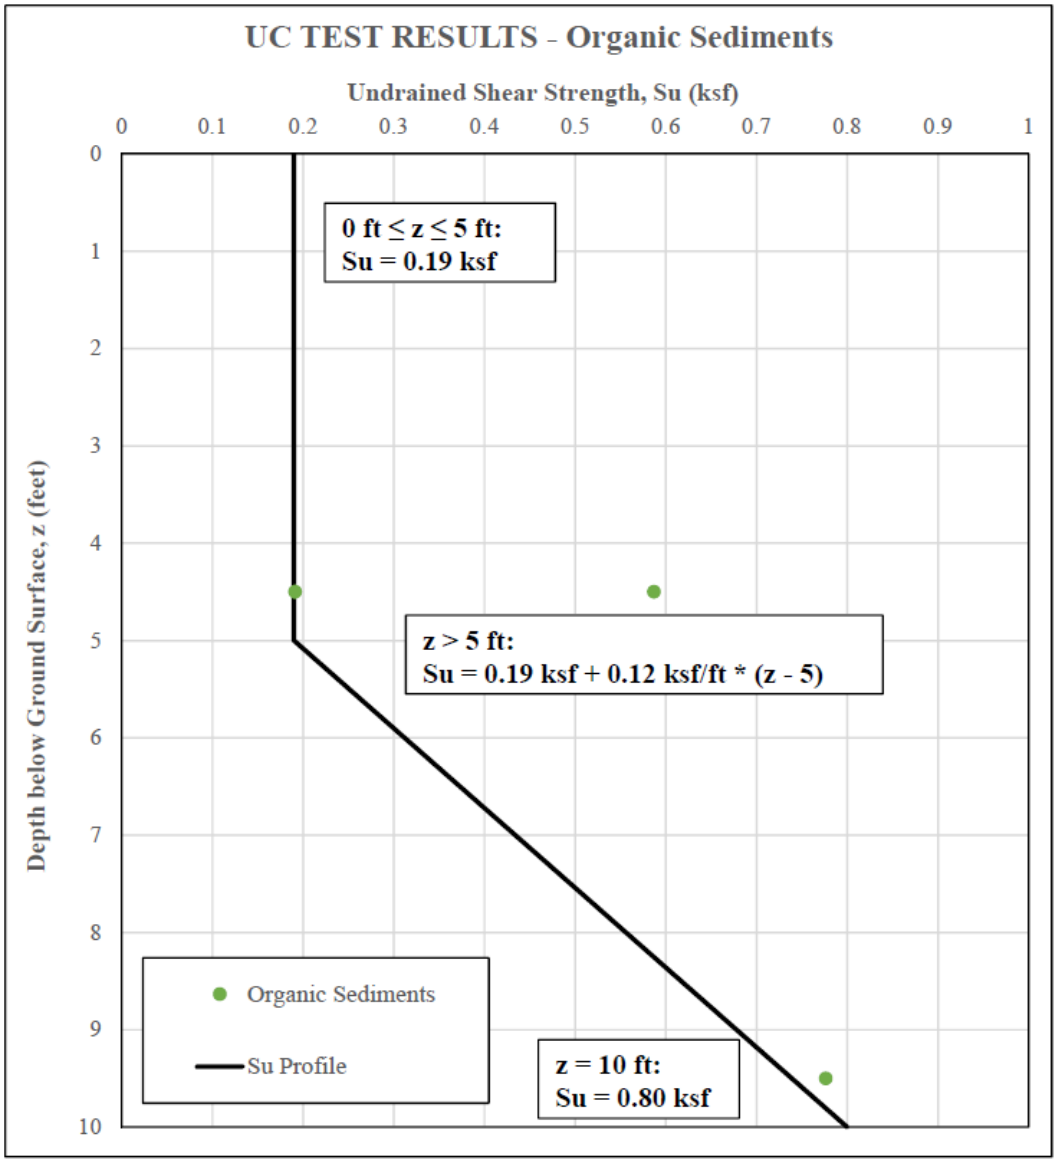

Figure 16. Undrained Strength of the Organic Sediments

Buttress

The Buttress is a design feature in the West Ash Pond system that consists of placed clay material. Buttress samples were collected and unconsolidated-undrained triaxial tests (4) and direct shear tests (3) were performed by Geotechnology, Inc. to during construction of the buttress, as part of Geosyntec's Construction Quality Assurance (CQA) services at the site. Geotechnical design perimeters for the placed buttress material were developed based on these tests.

The Buttress material was assigned a design unit weight of 125 pcf based on the mean value of laboratory measurements, as shown in Table 2.

Table 2. Summary of Laboratory Measured Clay Buttress Unit Weights

Boring ID	Lab Test	Total Unit Weight (pcf)
CB-01	Unconsolidated-undrained Triaxial Tests	124.4
CB-02		124.2
CB-02		124.0
CB-04		124.7
CB-01	Direct Shear Tests	124.3
CB-01		124.8
CB-01		124.9
CB-02		125.1
CB-02		124.7
CB-02		124.7
CB-04		128.9
CB-04		130.5
CB-04		129.0

The design undrained shear strength of 900 psf for the Buttress material was selected using the approximate lower third value from unconsolidated-undrained triaxial laboratory test results as seen in Figure 17.

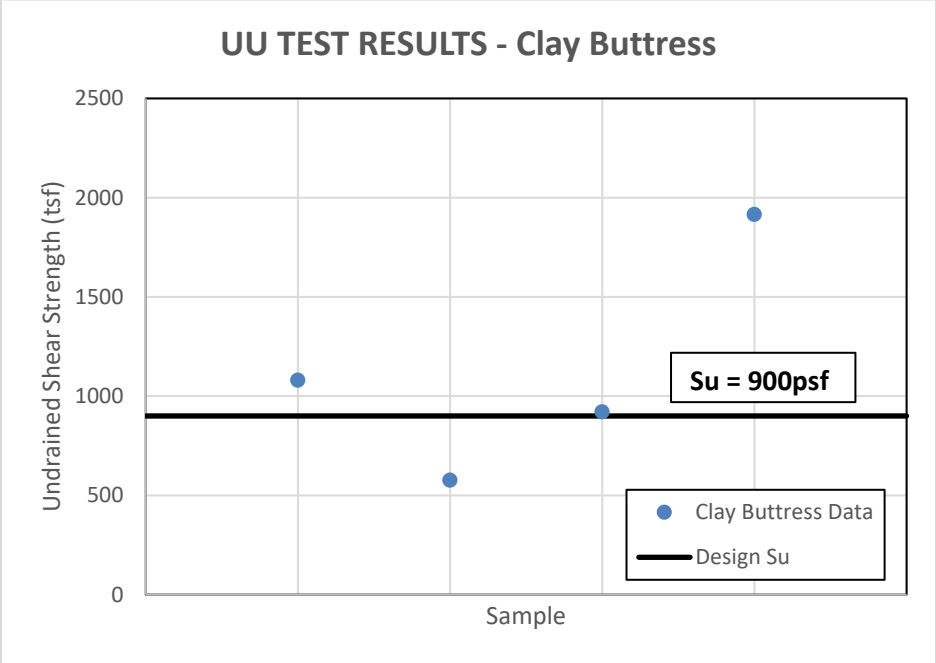

Figure 17. Undrained Strength of the Clay Buttress

The drained shear strength of the Buttress material was selected based on direct shear tests. Failure for direct shear specimens was defined as peak shear stress, limited to 10% shear strain. Based on the direct shear data shown in Figure 18, a design friction angles of 34 degrees and cohesion of 75 psf was selected.

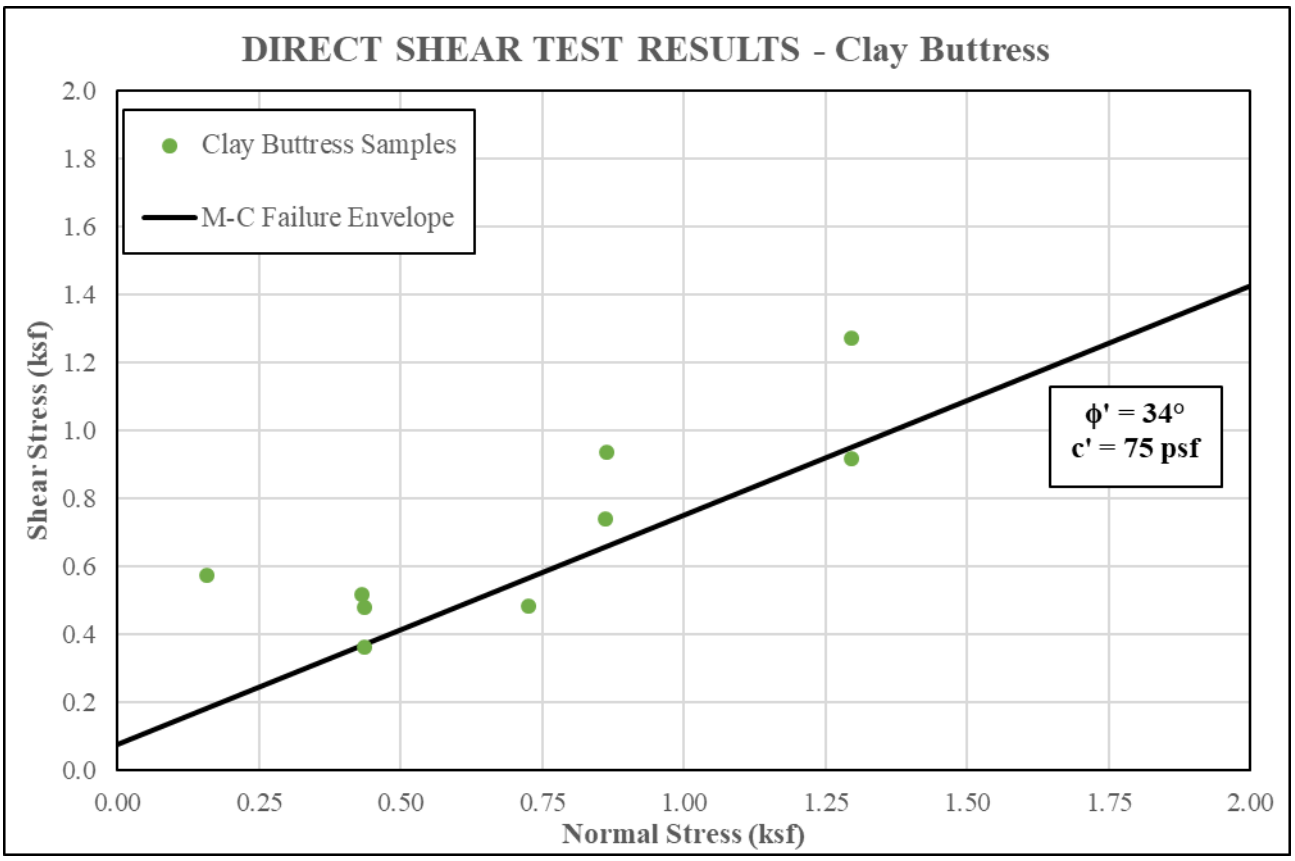

Figure 18. Drained Shear Strength of Clay Buttress

Groundwater Conditions

Groundwater conditions were estimated separately for long-term slope stability analyses, short-term slope stability analyses, and liquefaction screening analyses.

Groundwater conditions beneath the dike and impounded CCR for long-term slope stability analyses were selected to represent hydrostatic conditions that will develop within the CCR and foundation soils after the final cover system is installed. Natural Resource Technology (NRT) prepared a Hydrostatic Modeling Report for the Hennepin West Ash Pond System (NRT, 2017). The report found that total hydraulic head at the bottom of the CCR will reduce to near-zero within five years after cover construction is complete.

Therefore, the groundwater elevations for these analyses were assumed to be either equal to the CCR/foundation soil interface, or El. 447 feet (the approximate upper-most historic normal elevation of the adjacent Illinois River, as found from the LaSalle, IL gauging station [USACE, 2018]), whichever is higher. The CCR/foundation soil interface varies from approximately El. 450 to El. 440 ft across the site, but it generally similar to El. 447 ft. Groundwater conditions at and beyond the downstream toe of the dike were assumed to be equal to the ground surface or the upper-most historic normal Illinois River elevation of El. 447 ft, whichever was higher. For cross-sections adjacent to the Illinois River, a pool elevation of 442 ft was used; this is the approximately the lower-limit historic normal pool elevation (higher pool elevations provide more resisting force and therefore may be slightly unconservative).

Groundwater conditions for short-term slope stability analyses are only required at splitter dike Cross-Section A, where a sheet pile wall will be installed to support closure-by-removal excavation of the OWPP. This will occur prior to construction of the cover system, and therefore the use of long-term groundwater levels is not appropriate. At this cross-section, a groundwater elevation within the CCR corresponding to El. 452.4 ft was used, which corresponds to the groundwater elevation observed in 2017 Geosyntec test pit GS-T07. A groundwater elevation of 451 ft was used beneath the splitter dike, which corresponds to the normal pool elevation in the Old West Polishing Pond the November 2017 reading from piezometer HEN-P002.

Groundwater conditions for liquefaction screening analyses were taken as the groundwater elevation encountered at the time of CPT advancement, or El. 447 ft (approximate upper-most historic normal elevation of the adjacent Illinois River), whichever was higher.

5. LIQUEFACTION AND CYCLIC SOFTENING SCREENING ANALYSIS

The liquefaction screening analysis was performed using CPT-based methodology (Boulanger and Idriss, 2014) for the Sand and Gravel Dike Fill and Sand and Gravel Alluvium.

All liquefaction analyses were performed for a design seismic event with a 2% probability of exceedance within 50 years (e.g. 2,475-year return period earthquake). The design seismic event was selected using United States Geological Survey (USGS) 2008 probabilistic seismic hazard deaggregation data for the Site. The seismic site

classification was found to be Site Class D in accordance with ASCE 7-10 (ASCE, 2013), resulting in a site-class amplified peak ground acceleration of 0.117 g for the Site. The design earthquake magnitude was selected to be 6.11, which is the mean earthquake magnitude for the Site and is corresponds to background seismicity. Less than 15% of the seismic hazard at the Site is due to larger-magnitude earthquakes in the New Madrid Seismic Zone, as the Site is located approximately 300 miles to the north. Therefore, the mean earthquake magnitude of 6.11 is appropriate for design.

CPT-Based Liquefaction Triggering of Sand and Gravel Soils

Liquefaction triggering of the coarse-grained soils comprising the dikes and dike foundations were evaluated using the CPT-based approach by Boulanger and Idriss (2014). Fines content values were based on available laboratory test data and soil behavior types indicated by the CPTs. The soils were considered susceptible to liquefaction if calculated liquefaction factors of safety (FS_{liq}) were 1.1 or less. Only saturated soils were evaluated for liquefactions triggering, as unsaturated soils are not susceptible to liquefaction.

The analysis did not identify any laterally or vertically continuous zones of soil that were susceptible to liquefaction triggering during the design seismic event. Therefore, it can be concluded that liquefaction triggering is unlikely to occur in the Sand and Gravel Dike Fill or CCR structural fill beneath the perimeter dike. As a result, peak drained shear strength parameters can be assigned to the Sand and Gravel Dike Fill and Sand and Gravel Alluvium and peak undrained shear strength parameters can be assigned to structural fill beneath the perimeter dike for post-earthquake stability analysis.

Cyclic Softening Triggering Analysis of Clay and Silt Soils

A cyclic softening triggering analysis using the CPT-based approach by Idriss and Boulanger (2008) was performed to investigate the susceptibility of clay and silt soils to lose strength as a result of a seismic cyclic load. The approach estimates magnitude scaling factors and cyclic resistance ratios specific to clay and silt soils to evaluate a factor of safety against cyclic softening, $FS_{\gamma=3\%}$ (generating peak shear strains of 3% during cyclic loading). The soils would be considered susceptible to cyclic softening if the calculated factors of safety were less than 1.2.

Critical sections for this analysis were defined as sections that had relatively low post earthquake slope stability factors of safety. The two CPT's that were selected were adjacent to the two defined critical sections. Based on the results of the analysis, cyclic softening of clay and silt soils at the site is unlikely, as cyclic triggering factors of safety were approximately 2.3 and higher.

Seismic Demand Triggering of CCR

Triggering of liquefaction within the CCR below the Splitter Dike was estimated using a seismic demand approach. This is because the seismic demand approach compares the calculated cyclic stress ratio and number of seismic loading cycles during the design seismic event to the cyclic resistance ratio of the CCR at the same number of loading cycles. The cyclic resistance ratio of the CCR was based on published data from Wolfe and Butalia (2010) and is based on cyclic triaxial tests performed by the Ohio State University on reconstituted specimens of sluiced CCR. The cyclic resistance ratio was adjusted to account for site-specific overburden stresses following Youd et al. (2001) and was adjusted to account for both differences in laboratory vs. field loading and cyclic triaxial loading vs. cyclic direct simple shear loading following Seed (1979) and Bray and Sancio (2006), respectively. Both upper- and lower-bound cyclic resistance ratios of the CCR were then plotted vs. number of loading cycles to develop site-adjusted characteristic liquefaction triggering curves.

The Site-specific seismic demand was estimated to be a cyclic stress ratio of 0.08 for CCR beneath the crest of the dikes and 0.09 for CCR beneath the toe of the dike, using the Boulanger and Idriss (2014) liquefaction triggering methodology. The number of cyclic loading cycles from the design earthquake was estimated to range from 11 to 37 (Liu et al., 2001). The anticipated cyclic stress ratios and number of loading cycles were plotted on the characteristic liquefaction triggering curves for CCR present beneath the crest of the dike (Figure 19) and beneath the toe of the dike (Figure 20). As shown in Figures 20 and 21, seismic loading at the site is approximately 50% of the lower-bound loading required to cause liquefaction of the CCR. Therefore, it can be concluded that liquefaction triggering of CCR beneath the dikes of the OWAP is unlikely during the design seismic event, and peak undrained strengths can be used for CCR in post-earthquake slope stability analyses.

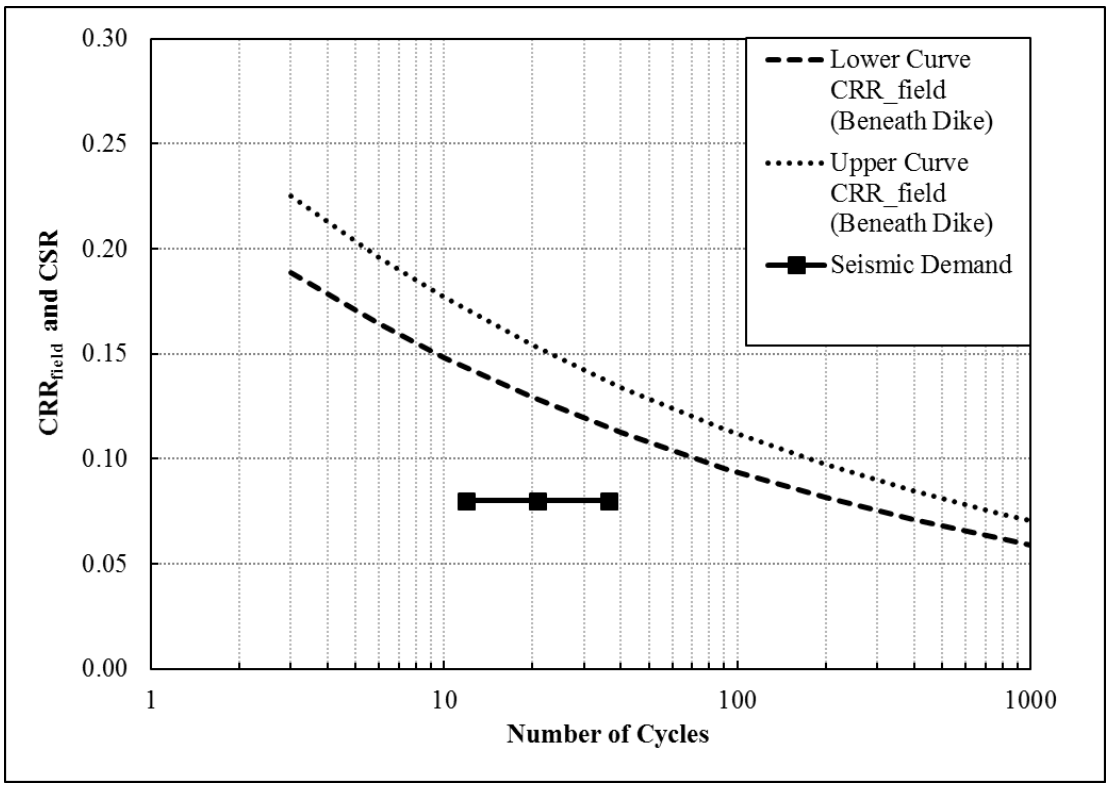

Figure 19. Seismic Demand versus Resistance for CCR Below the Dike Crest

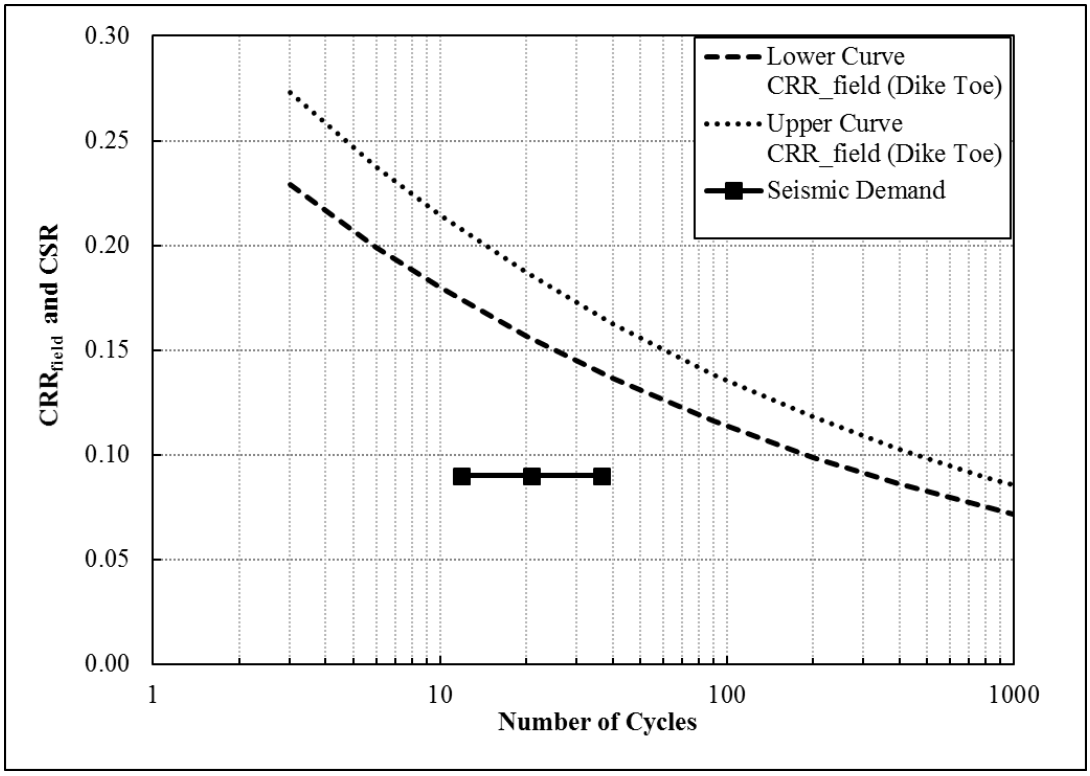

Figure 20. Seismic Demand versus Resistance for CCR Below the Dike Toe

Saturated CCR within the interior of the OWAP (below the assumed long-term groundwater level of elevation 447 feet) was conservatively assumed to be susceptible to liquefaction triggering. Only limited laboratory test data or CPT data was available on this material. The material comprises a limited thickness under most of the OWAP (i.e. 1 to 3 feet) and does not underlie the dikes. Therefore, liquefaction in this material does not have a significant effect on the stability of the OWAP perimeter dikes. The post-liquefaction residual shear strength of the saturated CCR was assumed to be a c/p' ratio of 0.045, which corresponds to a lower-bound value for clean sand, per Idriss and Boulanger (2008).

6. GLOBAL SLOPE STABILITY

Stability analyses for the OWAP were performed using limit-equilibrium SLIDE version 7.0 (Rocscience, 2017) software to calculate the factor of safety (FS) of the perimeter dikes around the West Ash Pond against global instability. Slope stability analyses

utilized the Spencer's method (1973) and evaluated both circular and non-circular optimized slip surfaces. Slope stability analyses were not performed for the OWPP as the OWPP will be closed by removal of CCR and the perimeter dikes. Slope stability analyses were analyzed for the following loading conditions:

Long-Term Static Conditions: This loading condition corresponds to the stability of the OWAP dikes under long-term, normal operating conditions with estimated static groundwater levels. Drained material properties, representing effective stress conditions, are used for all materials, as this condition corresponds to static conditions without the application of pore-pressure inducing loads. The minimum acceptable FS for this loading condition is 1.50, per the USEPA CCR Rule (USEPA, 2015).

Pseudostatic Seismic Conditions: This loading condition corresponds to the stability of the OWAP dikes under short-term seismic shaking conditions. Peak undrained material properties are used for all cohesive materials and peak drained shear strengths are used for all free-draining materials. The seismic loads are modeled as an outward-acting horizontal force. Upper-bound seismic loads were selected to be 0.015 g following the Bray and Travasarou (2009) methodology[1]. The minimum acceptable FS for this loading condition is 1.00, per the USEPA CCR Rule (USEPA, 2015).

Post-Earthquake Conditions: This loading condition corresponds to the stability of the OWAP dikes immediately following a seismic event. The liquefaction and cyclic softening analyses discussed in Section 5 did not identify materials expected to undergo liquefaction or cyclic softening for the design seismic event. Therefore, peak undrained strengths are used for cohesive materials not susceptible to liquefaction or cyclic softening triggering (e.g. silt and clay dike fill, silt and clay alluvium, and CCR), and peak drained strengths are used for free-draining materials not susceptible to liquefaction triggering (e.g. sand and gravel dike fill and sand and gravel alluvium). The minimum acceptable FS for this loading condition is 1.20, per the USEPA CCR Rule (USEPA, 2015).

[1] The Bray and Travasarou (2009) methodology utilizes a user-defined maximum tolerable deformation, which was assumed to be 1.0 ft, following *RCRA Subtitle D (258), Seismic Design Guidance for Municipal Solid Waste Landfill Facilities* (USEPA, 1996). If the calculated pseudostatic seismic factor of safety is above 1.00, the deformation is expected to be less than 1.0 ft.

All slope stability analyses include proposed post-closure grades within the OWAP and OWPP, and the estimated long-term groundwater levels. For the Splitter Dike between the closure-in-place OWAP and closure-by-removal OWPP, a temporary sheet pile wall was designed to maintain stability of the Splitter Dike during short-term closure-by-removal excavation. A permanent compacted clay buttress was designed for Section A-A' to maintain long-term static, pseudostatic, and post-earthquake stability of the Splitter Dike, and the analysis did not include any stabilization affects from the sheet pile wall; this is because the sheet pile wall may be removed upon installation of the buttress.

Subsurface material interfaces at each cross-section were developed using available boring data (Section 3), including interpolations between borings using available historic data (AECOM, 2016) and engineering judgment.

Selected Cross-sections

The critical sections for the OWAP were selected based on the dike height, dike slope, and thickness of the Silt and Clay Alluvium beneath the dike (Table 3). On the west side, Section A-A' was selected to represent the stability of the Splitter Dike between the OWAP and OWPP and contains a thick zone of Silt and Clay Alluvium. On the north side, Sections B-B' and C-C' were selected due to a thick zone of the Silt and Clay Alluvium and relatively steep (3.1H:1V) exterior dike slopes, respectively. On the south side, Section F-F' was selected due to relatively steep exterior dike slopes. Dike slopes were measured based on pre-construction conditions; slopes will generally remain a similar height after closure is completed.

Table 3. Summary of Cross-Sections Investigated for Stability Analyses

Section ID	Dike Height (feet)	Dike Slope	Thickness of Silt and Clay Alluvium (feet)
A-A'	21.5	3.4H:1V	45 at HEN-B001
B-B'	17	3.7H:1V	28 at HEN-B004
C-C'	18	3.1H:1V	0 at HEN-B006
F-F'	17	2.9H:1V	19 at HEN-B012

Cross-section locations are shown on attached Drawing 1. Slope stability analyses for the excavated portions of the dikes where rock-lined stormwater chutes are proposed were not performed. The dike crest will be lowered at these locations, by approximately 3 to 5 feet, and the slope will be graded to approximately 3H:1V. Therefore, these sections are not critical for slope stability due to the lowered dike height.

Results

The results of each of the design scenarios is presented in Table 4. Both circular and non-circular slip surfaces were evaluated, for each analysis case and cross-section, and the lower FS from the two slip surface shapes are presented. The output from SLIDE is provided in Appendix A for each of the design scenarios and Sections.

Table 4. Results of Stability Analyses

Loading Condition	Minimum Factor of Safety	Calculated Factor of Safety			
		A-A'	B-B'	C-C'	F-F'
Long-Term Static	1.50	1.86	2.10	1.51	1.91
Pseudostatic Seismic	1.00	1.15	1.37	1.61	1.42
Post-Earthquake	1.20	1.30	1.46	1.66	1.49

7. SHEET PILE WALL DESIGN

This section addresses the design of a temporary steel sheet pile (SSP) wall along the west side of the OWAP that will be installed to allow for closure by removal of the OWPP. Geosyntec Consultants completed the initial structural design of the SSP; the design was later independently reviewed by an Illinois-Licensed structural engineer, and the design drawings of the SSP were later sealed by the Illinois-Licensed structural engineer. The review memo is provided in Attachment G. Global slope stability analyses were completed by Geosyntec Consultants.

Selected Cross-section

Cross-section Section A-A' was used for design, as discussed in Section 6. This is considered the critical cross section because it has the largest unsupported wall height and a relatively thick zone of alluvial silts and clays within the subsurface. The same subsurface stratigraphy, soil properties, and groundwater conditions used for the slope stability analyses at Section A-A' were used for the SSP wall design.

The groundwater table behind the wall was assumed to be at E. 451 ft; this is the elevation measured by existing piezometers and the approximate normal pool elevation in the OWPP and was used because the sheet pile wall was assumed to be impermeable. The groundwater table in front of the wall was assumed equal to the closure-by-removal ground surface in the OWPP (El. 440.4 ft), resulting in 10.6 ft of hydrostatic imbalance. The proposed buttress at Section A-A' was not included in the analysis, as this buttress will not be constructed until after closure-by-removal of the OWPP is complete.

Methodology and Assumptions

Internal and global stability analyses were performed. All loads were assumed static, and both drained and undrained loading conditions were considered for the temporary scenario. The internal and global stability analyses outputs for the SSP wall design are provided in Appendix B.

Internal Stability Analyses

Internal stability analysis was performed utilizing Shoring Suite version 8.16h (CivilTech, 2015) software. CT Shoring was used to compute earth pressure, surcharge loads, shear forces, and wall bending moments, acting on or within the SSP wall. For the cantilevered condition, "fixed-earth" behavior was assumed, wherein design pressures are computed using simplified distributions without consideration of moment reductions due to flexure, displacement, and stress redistribution. The calculated maximum shear loads, bending moments, and required embedment from the internal stability analyses were used to select the appropriate SSP size and length for the wall. A 20% increase was applied to the embedment depth calculated to satisfy moment equilibrium, in order to calculate an embedment depth that would satisfy force equilibrium.

Both drained and undrained loading conditions were analyzed. For undrained analyses ($\varphi=0$, $c=s_u$), it is possible to calculate negative active earth pressures using classic earth pressure theory equations (e.g., Coulomb). For these analyses, negative active earth pressures were resolved to zero.

The following assumptions were used for the analyses applicable at all cross sections:

- Sheet piles will be Grade 50 steel. Following guidance in the American Institute of Steel Construction (AISC) Manual, 13th Edition (2005), the allowable bending stress (F_b), is 0.6 × 50 ksi = 30 ksi;

- The sheet piles will be free to deflect normal to the plane of the wall and thus active earth pressures will develop;
- Lateral earth pressures were calculated following Coulomb theory;
- A wall-to-soil interface friction angle of 10 degrees was applied for all interfaces;
- For the silt and clay alluvium, a drained friction angle of 30°, representing the shear strength determined from CIU triaxial tests, was used for earth pressure calculations instead of the friction angle calculated from direct shear strength tests. This is because the base angle of the active and passive wedges will be non-horizontal and oriented in a manner similar to a triaxial compression test, rather than a direct shear test.
- Seepage below the sheet pile tip was neglected because the sheet piling extends through the low permeability silt and clay alluvium unit and the sheet pile is assumed to act as a hydraulic cutoff;
- For undrained analyses, it was assumed that the CCR material would behave drained. Excess pore pressures that may develop within the CCR are expected to dissipate more rapidly than the silt and clay alluvium and thus behave drained relative to the native materials. Furthermore, assuming the CCR behaves drained imposes a greater load on the SSP wall which conservatively models the CCR loading on the SSP;
- A 1.3 reduction factor was applied to the passive wedge for the CCR removal scenario (temporary loading); and
- The required moment of inertia to limit deflection of the wall was calculated. For the dredging scenarios, the deflection was limited to three inches, based on Geosyntec's experience in temporary shoring design in both urban- and non-urban environments. Deflection was calculated at the top of retained material.

Net apparent lateral pressure distributions, shear diagrams, and bending moment diagrams are provided in Appendix B.

Global Stability Analyses

Global stability was analyzed using the same software and approach discussed in Section 6. For the global stability analyses, both rotational (circular) and optimized wedge (block) mechanisms were analyzed for each scenario and condition. The global stability analyses

were used to verify that the embedment required for internal stability would be adequate for the global stability.

The following assumptions were used for the analyses:

- The steel sheet pile material was modeled as a 1-ft thick material with 150 pcf unit weight and infinite strength. This selection was made to prevent potential failure surfaces from extending through the bulkhead in the analyses; and

- Failure surface entry points were limited to the upslope side of the SSP and exit points for were limited to within the OWPP.

The minimum FS for global end-of-construction stability is 1.30 per the USEPA CCR Rule. This loading condition is appropriate for use in designing the temporary SSP wall for the splitter dike.

Interim Construction Global Stability Analyses

The global stability of the splitter dike was analyzed for conditions where a crane is placed on the dike, for installation of a sheet pile wall, but the wall has not yet been fully installed. This case is intended to evaluate the stability of the dike, under construction surcharge loading, for temporary construction conditions. The construction contractor, Ryan Central, Incorporated (Ryan), proposes to lower the splitter dike by approximately 2 feet or more. Although Ryan originally proposed using a 3H:1V slope, initial calculations indicates that this may not provide an acceptable factor of safety, so a 4H:1V slope was used in the analysis between the sheet pile wall location to the lowered crest of the splitter dike.

The crane will be driven along the south dike to reach the working area; therefore, stability of the south dike was evaluated at cross-section F-F'.

A Link-Belt LS-218H II crane (110-ton) will be used to install the sheet pile wall. The weight of the crane, sheet pile, hammer, and other equipment is expected to weigh 210,906 lbs (maximum operating crane weight of 193,906 lbs, plus 17,000 lbs for the sheet pile and hammer) (Ryan Central, 2019). This results in a track surcharge of 1,970 psf or a surcharge of 990 psf if mats are placed beneath the crane (equal to the exterior area of the crane tracks or larger) when the tracks are retracted and 680 psf when the tracks are extended. For the case of the crane driving on the south dike, only the operating

weight of the crane was included, and no crane mats were used, resulting in a track surcharge of 1,810 psf.

Using these loading magnitudes, surcharges were applied to the downstream edge of the dikes to represent the crane loading. The slope stability analysis was performed using the same software and approach discussed in Section 6. Both rotational (circular) and optimized wedge (block) mechanisms were analyzed for each scenario. At the splitter dike separate analyses were performed considering drained and undrained soil properties; on the south dike, only undrained conditions were considered as the crane loading is expected to be transient (i.e. loading for a few hours or less).

The minimum FS for global interim construction stability is 1.30 per the USEPA CCR Rule. Preliminary analyses indicated that the splitter dike would have a factor of safety below 1.30 if crane mats were not used, so the analyses were updated assuming that crane mats were present. The analyses performed on the south dike at cross-section F-F' resulted in a factor of safety greater than 1.30.

Results

Summaries of the results of the analyses are provided in Tables 5 and 6 for the internal stability analyses and global stability analyses, respectively. Interim construction global stability analyses are summarized in Table 7.

Table 5. Summary of Internal Stability Analyses for SSP Wall Design

Scenario	Condition	Max Bending Moment, M_{max}	Required Plastic Section Modulus, Z_x	Max Shear, V_{max}	Required Moment of Inertia, I	Required Embedment, D	Minimum Pile Length, L(2)	Deflection
		(ft*kip/lf)	(in^3/ft)	(kip/ft)	(in^4/ft)	(ft)	(ft)	(in)
Cut El. 440.4'	Undrained	100.6	40.3	12.5	419.9	39.5	53.5	2.6
Cut El. 440.4'	Drained	119.4	47.9	24.3	419.9	34.2	48.2	2.1

Notes
1) Required moment of inertia to limit deflection. For CCR removal from the OWPP the limit is 3 inches.
2) Top of pile is at El. 454.4feet.

Table 6. Summary of Global Stability Analyses for SSP Wall Design

Loading Condition	Minimum Factor of Safety	Calculated Factor of Safety Section A-A'
Drained	1.30	1.98
Undrained	1.30	1.55

Table 7. Summary of Interim Construction Global Stability Analyses for Crane Loading Conditions

Crane Track Spacing	Loading Condition	Minimum Factor of Safety	Calculated Factor of Safety	
			Section A-A'	Section F-F'
Retracted	Drained	1.30	1.96	-
	Undrained	1.30	1.31	1.32
Extended	Drained	1.30	2.32	-
	Undrained	1.30	1.41	-

The SSP wall along the existing splitter dike at the Hennepin West Ash Complex will be a cantilevered sheet pile wall consisting of one type of section. The required sheet pile section is NZ 26 (equivalent or better) and minimum 53.5 ft long (39.5 ft minimum embedment depth, with a maximum free height of 14 ft). Top of sheet piling shall be set level with the ground surface along the proposed alignment. The ground surface typically ranges from El. 453 to 454 ft, although it reaches approximately El. 460 ft at the north and south ends of the wall. During sheet pile installation, construction surcharges on the splitter dike should be limited to 990 psf and crane mats should be used.

8. OLD WEST POLISHING POND SEEPAGE ANALYSIS

Seepage analyses were performed to evaluate groundwater inflows during closure by removal excavation of the OWPP so that they can be provided to the construction contractor for their use in excavation groundwater inflow management. Seepage analyses were performed using the two-dimensional finite-element seepage analysis module within the SLIDE Version 7.0 software package (Rocscience, 2017).

Four cross-sections (G, H, I, and A) were analyzed, with each section representing each of the four sides of the OWPP. Cross-section locations are shown on attached Figure 1.

Subsurface stratigraphy for each cross-section was developed in AutoCAD Civil3D using available boring data and was imported into SLIDE. Data from existing piezometers present at each cross-section (HEN-P001, GS-P07, GS-P08, and HEN-P002, respectively) were used to develop the phreatic surface profile.

Seepage analyses were first performed for existing conditions to calibrate the seepage models to piezometric conditions observed in November of 2017 (the date of Geosyntec's field investigation [Geosyntec, 2018]). The existing conditions included a pool elevation of 451 ft within the OWPP based on the 2015 Weaver Consultants survey of the site and is assumed to represent the normal pool in the OWPP based on Geosyntec's visual site observations. Far-field groundwater conditions (i.e. curb conditions) were assumed to be El. 443 ft, based on the approximate elevation of the Illinois River during November of 2017. Hydraulic conductivities for subsurface materials (Sand and Gravel Dike Fill, CCR, and Sand and Gravel Alluvium) were based on available information collected by Geosyntec (2018) and others (NRT, 2017). The hydraulic conductivity of the Silt and Clay Alluvium at each section was adjusted during calibration until the modeled total head at each section's piezometer matched the measured head from November of 2017 within 0.2 ft. Table 8 lists the calibrated hydraulic conductivity values for each cross-section and how each value was determined.

Table 8. Summary of Hydraulic Conductivities used for Seepage Analyses

Cross-Section	Calibrated Hydraulic Conductivity							
	Sand & Gravel Dike Fill		CCR		Silt & Clay Alluvium		Sand & Gravel Alluvium	
	k^1 (cm/sec)	Source	k^3(cm/sec)	Source	k^1 (cm/sec)	Source	k^1 (cm/sec)	Source
G	$1x10^{-2}$	NRT (2017)	$8.2 x10^{-6}$	Rebound Testing[2] (Geosyntec, 2018)	$1 x10^{-6}$	Calibration	$1 x10^{-2}$	NRT (2017)
H					$3 x10^{-6}$			
I					$8 x10^{-6}$			
A			$6x10^{-6}$	Hydraulic Conductivity Testing[3] (Geosyntec, 2018)	$5 x10^{-6}$			

Notes:
[1]All hydraulic conductivity values are horizontal. Vertical hydraulic conductivity was assumed to be 50% of the horizontal hydraulic conductivity for all cross-sections.
[2]CCR hydraulic conductivity based on pumping and rebound tests of piezometers installed at each cross-section. The CCR at these cross-sections is generally a mixture of native soil, slag, and coal, per the boring logs.
[3]CCR hydraulic conductivity based on laboratory vertical permeability testing of samples collected from the Old West Ash Pond. Horizontal hydraulic conductivity was assumed to be 5 times the vertical hydraulic conductivity, based on Geosyntec's experience and calibration. The CCR at this cross-section is predominantly fly ash.

Section A represents the side of the OWPP that is connected to the OWAP where a sheet pile wall will be constructed to facilitate OWPP removal. The sheet pile wall will be constructed using hot-rolled NZ 26 sheets with Larssen interlocks. The interlocks will not be sealed. For seepage analysis, the sheet pile was modeled as an equivalent one-meter thick slurry wall. The hydraulic conductivity of the sheet pile wall was calculated as 2.86×10^{-5} cm/sec using published methodologies (ArcelorMittal, 2015). After the seepage analysis for each cross-section was calibrated, the seepage analyses were modified to represent conditions that may occur during closure-by-removal excavation of the OWPP. These cases include:

- **Pond Unwatered**: This case represents seepage inflows that are expected to occur when the free water pool is pumped out of the OWPP, but prior to closure-by-removal excavation. The interior of the OWPP was modeled as a potential seepage face. The far-field curb boundary condition was assumed as a groundwater level equal to the far-field ground surface (Sections G, H, and I). For Section I, the Illinois River pool elevation was assumed as El. 447 ft, which is the upper-most historic normal elevation of the river (USACE, 2018). A sheet pile wall was not

assumed to be installed at Section A, as the sheet pile may not be installed until after unwatering is complete, and the sheet pile will reduce seepage inflows once installed.

- **Pond Unwatered – River Flood Stage:** This case is similar to the Pond Unwatered case but assumes that the Illinois River is at flood stage (El. 450 ft [USACE, 2018]).
- **Pond Excavated:** This case is similar to the Pond Unwatered case but assumes that the three exterior dikes of the OWPP (north, west, and south) have been completely removed and that final closure-by-removal excavation grades have been reached in the OWPP. Far-field groundwater levels and Illinois River pool elevations were assumed to be the same as the Pond Unwatered case. The sheet pile wall was included in this analysis.
- **Pond Excavated – High River:** This case is similar to the Pond Excavated case but assumes that the Illinois River is at a higher stage (El. 448 ft). This is the rim elevation of the excavation, and the Illinois River would flow into the excavation if it exceeded El. 448 ft. The sheet pile wall was included in this analysis.

Estimated inflows for each cross-section were multiplied by the length of the side of the OWPP representing each section and added together to develop a single excavation inflow value for the entire OWPP. Inflows are presented in both gallons per minute and gallons per day and are listed in Table 9. A factor of safety of 1.45 was applied to the seepage inflows, the corrected values are also presented in Table 9. The factor of safety was developed based on a factor of safety for design data of 0.10, experience of 0.10, and criticality of 0.25 (NAVFAC, 1983), these are then added together to get a factor of safety of 1.45.

In summary, excavation inflows are relatively low (approximately 1,000 to 7,000 gal/day, depending on scenario), primarily due to the thick layer of relatively low-permeability Silt and Clay Alluvium under the OWPP and the presence of the sheet pile wall between the OWPP and OWAP. Seepage analysis output is presented in Appendix D.

Table 9. Summary of Seepage Analyses

Scenario	Calculated Infiltration Rate			
Pond Unwatered	0.78	gal/min	1200	gal/day
Pond Excavated	3.15	gal/min	4600	gal/day
Pond Excavated (High River El. 448 ft)	3.37	gal/min	4900	gal/day
Pond Unwatered - River Flood Stage (El. 450 ft)	1.39	gal/min	2100	gal/day
	With Factor of Safety (FS=1.45)			
Pond Unwatered	1.14	gal/min	1700	gal/day
Pond Excavated	4.57	gal/min	6600	gal/day
Pond Excavated (High River El. 448 ft)	4.88	gal/min	7100	gal/day
Pond Unwatered - River Flood Stage (El. 450 ft)	2.02	gal/min	3000	gal/day

9. VENEER COVER STABILITY

Veneer stability refers to the shallow, translational stability of the cover system and each material interface within the cover system. While veneer stability calculations are not expressly required by the CCR Rule, they were performed to develop minimum interface friction specifications for construction purposes. Veneer stability calculations have been performed to determine minimum interface friction angles between each of the material interfaces. Material interfaces within the cover system include, from top to bottom:

- Cover soil against vegetative support soil (erosion layer),
- Geocomposite drainage layer or geotextile against cover soil,
- Geomembrane liner to geotextile or geocomposite drainage layer, and
- Subgrade against geomembrane liner.

Veneer stability for static loading conditions was evaluated following published methodology (Giroud, et al., 1995). Five final cover system slopes were evaluated at the site and represent critical veneer stability sections. The evaluated slopes are listed in Table 10 and shown in plan in Figure 21. Both the cover soil and vegetative soils were assumed to have a unit weight of 120 pcf and a drained friction angle of 27 degrees with zero cohesion, which is consistent with a compacted cohesive cover soil.

Table 10 – Slopes Evaluated for Veneer Stability

Slope	Location	Grade	Height (ft)	Length (ft)	Toe Elevation (ft)	Cushion Material	Reason for Selection
A	Western exterior	20%	6.7	33.9	462.5	Geocomposite	Tallest 20% slope with geocomposite
B	Western interior	2.10%	6.6	312.6	462.4	Geotextile	Tallest of the 2.1% slopes
C	Southern interior	19%	1.9	9.9	463.1	Geotextile	Tallest interior ~20% slope
E	Eastern exterior	20%	6.8	33.3	464	Geotextile	Highest 20% slope without a geocomposite

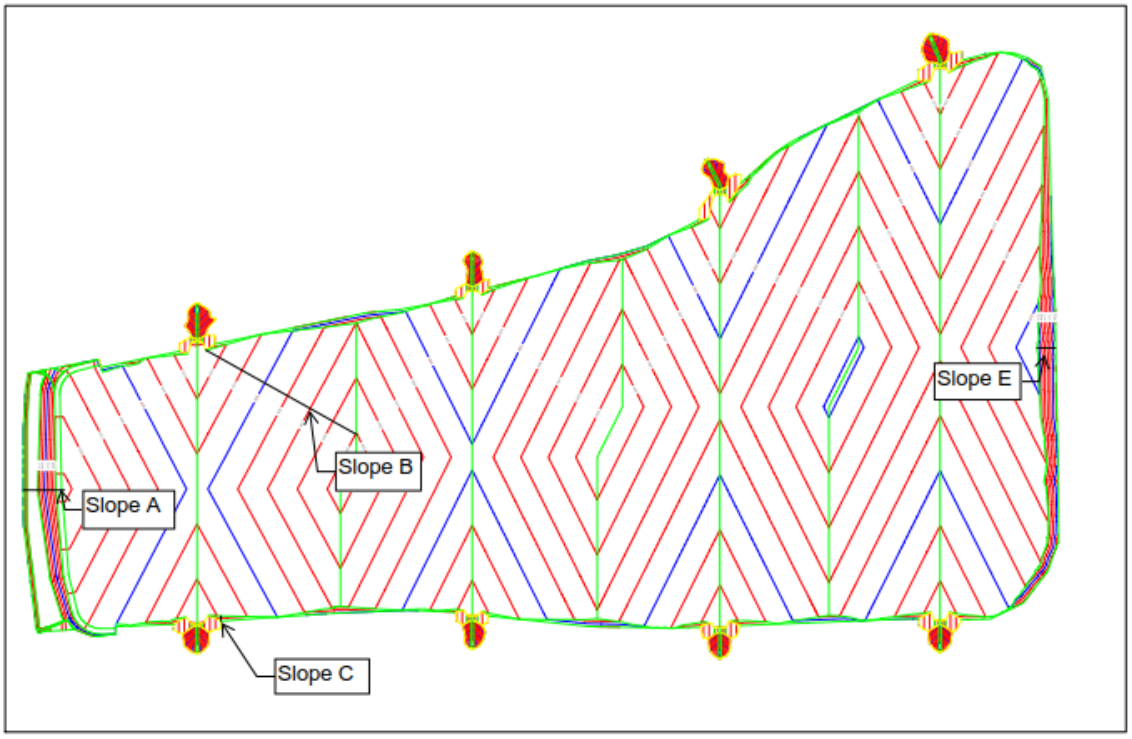

Figure 21 – Veneer Stability Slope Locations

Analyses were performed for the lower interfaces (one analysis for subgrade against geomembrane liner, geomembrane liner against geotextile or geocomposite drainage

layer, and geotextile or geocomposite drainage layer against cover soil, as the effective stresses would be the same for all three interfaces) and the upper interface (cover soil against vegetative soil, which was used to select the minimum shear strength of both soils). Each analyzed loading condition is described below:

Normal Conditions: This analysis considers the stability of the cover system under normal, static, steady-state operating conditions. The cover system soil is assumed to be unsaturated, and 0.25 inches of water is present within the geotextile (where present) which corresponds to a full thickness of water within a geotextile. For slopes with a geocomposite drainage layer (Slope A only), the head in the drainage layer was calculated as 0.13 inches based on the 25-year, 24-hour storm, following Giroud & Houlihan (1995) and was used for analysis. This is approximately half the geonet core thickness of 0.25 inches. The minimum acceptable FS for this condition is 1.50, as recommended by Koerner and Soong (1998). Minimum peak friction angles were calculated for this condition.

Saturated Conditions: This analysis considers the stability of the cover system under static, saturated operating conditions that may occur after a rainfall event on slopes that utilize a cushion geotextile in lieu of a geocomposite drainage layer. The cover system soil is assumed to be fully saturated, with two feet of water present (full cover thickness). A minimum acceptable FS for this condition of 1.20 was selected for design. This case was not analyzed for slopes that include a geocomposite, as the geocomposite was sized to convey infiltration resulting from the 25-year, 24-hour storm event, and therefore the cover soils are unlikely to become saturated when a geocomposite is used. Minimum peak friction angles were calculated for this condition.

Seismic Conditions: Veneer stability for seismic conditions was calculated following Matasovic (1991), for the same slope orientations as the static veneer analyses. Flood or saturated conditions were not considered for the seismic analyses as the likelihood of a flood event occurring at the same time as a seismic event is low. A pseudostatic seismic coefficient of 0.076 g was selected for analysis, which is 65% of the site-class amplified peak ground acceleration of 0.117 g, as recommended by Matasovic (1991). The minimum acceptable factor of safety for this condition is 1.00, as recommended by Matasovic (1991). Minimum peak friction angles were calculated for this condition.

Post-Earthquake Conditions: This analysis considers the stability of the final cover condition under conditions immediately after a seismic event, when seismic shaking has stopped. The seismic event may induce strains on the cover system, potentially straining the soils and/or interfaces to a reduced post-peak strength condition. The minimum factor of safety for this condition was assumed to be 1.20, which corresponds to the USEPA CCR Rule (USEPA, 2015) regulatory guidance for global dike stability. Minimum residual friction angles were calculated for this condition

The minimum design interface friction angles calculated for each interface are shown in Table 11. The friction angles reflect the highest calculated friction angle required to maintain the stability of the interface out of all analyzed loading conditions. No adhesion was assumed in the analyses.

Table 11. Calculated Minimum Interface Friction Angle for Final Cover Stability

		Calculated Minimum Interface Friction Angle (d, deg)					
	Interface	**Static Conditions (Min FS = 1.50)**	**Saturated Conditions (Min FS = 1.20)**	**Seismic Conditions (Min FS = 1.00)**	**Post-EQ Conditions (Min FS = 1.00)**	**Peak Design Interface Friction Angle (d_d, deg)[1]**	**Residual Large-Displacement Design Interface Friction Angle (d_d, deg)[1]**
Slope A	Lower Interfaces[2]	12.0	Not Evaluated	16.0	9.0		
	Vegetative Soil to Cover Soil	16.0	Not Evaluated	16.0	13.0		
Slope B	Lower Interfaces[2]	1	1	6	1		
	Vegetative Soil to Cover Soil	1	3	6	1		
Slope C	Lower Interfaces[2]	1	18	16	1		
	Vegetative Soil to Cover Soil	13	23	16	7		
Slope E	Lower Interfaces[2]	13.0	23.0	16.0	7.0		
	Vegetative Soil to Cover Soil	16.0	26.0	16.0	11.0		
Minimum Design Values	Lower Interfaces[2]	13.0	23.0	16.0	9.0	**23.0**	**9.0**
	Vegetative Soil to Cover Soil	16.0	26.0	16.0	13.0	**26.0**	**13.0**

Notes:

[1]Design interface friction angle is taken as the maximum calculated required interface friction angle for all evaluated loading

[2]Lower interfaces refer to geomembrane-to-subgrade, geomembrane-to-geotextile, and geotextile-to-cover soil. Friction angles were not calculated separately for each interface and refer to the most conservative hydraulic conditions for each interface.

10. GEOMEMBRANE PUNCTURE ANALYSIS

The cover system design at Hennepin includes a geomembrane with a 16-ounce geotextile cushion layer installed on top to provide protection from rocks or sharp objects within the cover soil. Rocks in the subgrade system (below the geomembrane) will be removed prior to geomembrane deployment, in accordance with the project specifications. A puncture analysis was performed on sand and gravel from the South Borrow Area at the site to determine its suitability as cover soil at the OWAP. Sand and gravel material parameters including grain size and angularity were determined based on laboratory testing. Puncture calculations were performed in accordance with GRI White Paper #14 (2008) and considered the following; gravel particles up to 3 inches in diameter, the presence of a 16-ounce geotextile on top of the geomembrane, 2 feet of soil on top of the geotextile, and a maximum construction equipment surcharge of 20 psi. The analysis resulted in a factor of safety of 3 against geomembrane puncture, indicating a low potential for puncture of the geomembrane.

An addition sensitivity analysis was performed for construction loading immediately after the geomembrane is installed (long-term chemical/biological degradation factor of 1.0, and a minimum factor of safety against puncture of 2.0). This analysis found that a maximum ground pressure of 34 psi may be applied to the geomembrane during installation. The 20 psi limit should be applied to long-term conditions after construction is completed.

Laboratory test results and puncture analysis calculations are provided in Appendix F.

11. SETTLEMENT ANALYSES

Settlements were calculated to evaluate post-settlement drainage grades (to check for hydraulic grade reversals in ditches) and to evaluate strains induced in geosynthetics. Closure of the OWAP will induce settlements in foundation soils due to added load (contoured fill and cover soil) and the long-term lowering of phreatic levels beneath the cover system, due to reduced infiltration. The ditches were designed with 1% slopes.

Compressibility parameters for CCR and the Silt & Clay Alluvium were estimated using available consolidation test data (AECOM, 2016; Geosyntec, 2018). Compressibility parameters for the Sand & Gravel alluvium were estimated using SPT N-value correlations (Hough, 1969) from borings at the OWAP advanced into the Sand & Gravel

Alluvium (AECOM, 2016; Geosyntec, 2018). Design compressibility parameters are provided in Table 12.

Table 12 – Design Compressibility Parameters

Material	Preconsolidaton Pressure (P'_p) (tsf)	Compression Index (C_c)	Recompression Index (C_r)	Initial Void Ratio (e_o)	Bearing Capacity Index (C)
CCR	1.5	0.306	0.025	0.84	Cohesive Material Consol. Settlement Only
Silt & Clay Alluvium	Normally Consolidated	0.274	0.018	1.28	
Sand & Gravel Alluvium	Free-Draining Material with Elastic Settlement Only				93

Settlements were calculated using one-dimensional consolidation theory. One-dimensional theory is appropriate for the site due to the gentle closure grades (approximately 2.2% in the middle of the OWAP). Settlements were calculated at 100-ft increments along five settlement sections: SS-1 through SS-5. SS-1 through SS-4 correspond to each of the four north-south stormwater channels while SS-5 corresponds to an east-west section along the highest planned fill thicknesses in the OWAP. Existing grades, post-closure grades, and subsurface material interfaces were taken from an AutoCAD Civil 3D model of the site.

Existing phreatic levels for each settlement analysis section were taken from recent piezometer and test pit data. Future groundwater levels were assumed to be El. 447 ft (the approximate upper-normal pool elevation in the Illinois River). Immediate settlements, consisting of recompression settlement of the CCR and settlement of the alluvial sand and gravel, was assumed to occur immediately (e.g. during construction). Long-term consolidation settlements (consisting of virgin compression of the alluvial clay) are expected to occur over a period of several years, after construction is complete. These settlements were used to calculate post-closure grades along each settlement section.

The settlement analyses found consolidation settlements of up to 15 inches at the highest fill areas (at the west side of the site). However, settlements decrease to near-zero around the perimeter of the OWAP because there is minimal added load. No areas of post-closure grade reversal, of either the stormwater ditches (SS-1 through SS-4) of the final cover peaks (SS-5), were identified.

In some limited areas, ditch grades reduced by up to 0.5% (post-settlement ditch grades grade of 0.5% compared to a design grade of 1%) but remained positive. In most areas, grades reduced by 0.1% or less. This indicates that settlement-induced grade reversals, and associated issues with stormwater drainage or ponding are unlikely due to settlement. Figures showing the location of each settlement section and profiles of the settlement analysis layering and results can be found in Appendix E.

12. CONCLUSIONS

The calculations presented herein demonstrate that the proposed closure plan for the Dynegy-Hennepin OWAP and OWPP will satisfy geotechnical dike stability criteria for static, seismic, and post-earthquake loading conditions. The sheet pile wall supporting the Splitter Dike between the OWAP and OWPP will satisfy geotechnical dike stability criteria (end-of-construction conditions) and during temporary excavation conditions. Additionally, the cover system veneer stability satisfies design criteria for static and seismic conditions. Lastly, closure-induced settlements are expected to be minor and unlikely to result in grade reversals or other settlement-induced drainage issues.

**********INPUT DATA**********

Wall Type: 1. Sheet Pile
Wall Height: 14.00
Pile Diameter: 1.00
Pile Spacing: 1.00
Factor of Safety (F.S.): 1.30
Lateral Support Type (Braces): 1. No
Top Brace Increase (Multi-Bracing): Add 15%*
Embedment Option: 1. Yes
Friction at Pile Tip: No
Pile Properties:
Steel Strength, Fy: 50 ksi = 345 MPa
Allowable Fb/Fy: 0.66
Elastic Module, E: 29000.00
Moment of Inertia, I: 419.9

CT Shoring Undrained Analysis Output

User Input Pile: NZ-26

* DRIVING PRESSURE (ACTIVE, WATER, & SURCHARGE) *

No.	Z1 top	Top Pres.	Z2 bottom	Bottom Pres.	Slope
1	0	0	3.3	.1	0.030303
2	3.3	0.1	13.9	1	0.084906
3	13.9	.525	25.9	1.13	0.050417
4	25.9	0.57	48.8	1.68	0.048472
5	48.8	1.3	94.3	2	0.015385

* PASSIVE PRESSURE *

The pressures below will be divided by a Factor of Safety =1.3

No.	Z1 top	Top Pres.	Z2 bottom	Bottom Pres.	Slope
1	13.90	0.90	25.90	1.50	0.0500
2	25.90	1.95	48.80	3.10	0.0502
3	48.80	11.00	94.30	28.45	0.3835

* ACTIVE SPACE *

No.	Z depth	Spacing
1	0.00	1.00
2	14.00	1.00

* PASSIVE SPACE *

No.	Z depth	Spacing
1	13.90	1.00

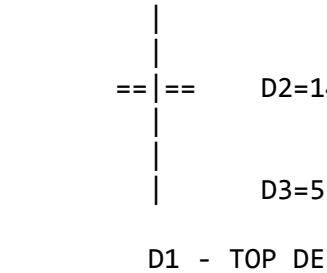
*For Tieback: Input1 = Diameter; Input2 = Bond Stength
*For Plate: Input1 = Diameter; Input2 = Allowable Pressure
*For Deaman: Input1 = Horz. Width; Input2 = Allowable Pressure; Angle = 0

**********CALCULATION**********

The calculated moment and shear are per pile spacing. Sheet piles are per one foot or meter; Soldier piles are per pile.

Top Pressures start at depth = 0.00

| D1=0.00
|



D1 - TOP DEPTH
D2 - EXCAVATION BASE
D3 - PILE TIP (20% increased, see EMBEDMENT Notes below)

MOMENT BALANCE: M=0.00 AT DEPTH=46.88 WITH EMBEDMENT OF 32.88
FORCE BALANCE: F=0.00 AT DEPTH=53.45 WITH EMBEDMENT OF 39.45

The program calculates an embedment for moment equilibrium, then increase the embedment by 20% to reach force equilibrium.
A Balance Force=12.51 is developed from depth=46.88 to depth=53.45
Total Passive Pressure = Total Active Pressure, OK!

**********RESULTS**********

* EMBEDMENT Notes *
Based on USS Design Manual, fist calculate embedment for moment equilibrium, then increased by 20 to 40 % to reach force equilibrium.
The embedment for moment equilibrium is 32.88
* The 20% increased embedment for force equilibrium is 39.45 (Used by Program)
The 30% increased embedment for force equilibrium is 42.74
The 40% increased embedment for force equilibrium is 46.03

Based on AASHTO 2002 Standard Specifications, fist calculate embedment for moment equilibrium, then add safety factor of 30% for temporary shoring; add safety factor of 50% for permanent shoring.
The embedment for moment equilibrium is 32.88
Add 30% embedment for temporary shoring is 42.74
Add 50% embedment for permanent shoring is 49.31

* BASED ON USS DESIGN MANUAL (20% increased), PROGRAM CALCULATED MINIMUM EMBEDMENT = 39.45
TOTAL MINIMUM PILE LENGTH = 53.45

* MOMENT IN PILE (per pile spacing)*
Pile Spacing: sheet piles are one foot or one meter; soldier piles are one pile.
Overall Maximum Moment = 100.62 at 31.30
Maximum Shear = 12.45
Moment and Shear are per pile spacing: 1.0 foot or meter

* VERTICAL LOADING *

```
Vertical Loading from Braces = 0.00
Vertical Loading from External Load = 0.00
Total Vertical Loading = 0.00

* DEFLECTION *
   I (in4)/foot=419.90
   Top deflection = 2.596(in)
   Max. deflection = 2.596(in)
```

*For Plate: Input1 = Diameter; Input2 = Allowable Pressure
*For Deaman: Input1 = Horz. Width; Input2 = Allowable Pressure; Angle = 0

**********CALCULATION**********

The calculated moment and shear are per pile spacing. Sheet piles are per one foot or meter; Soldier piles are per pile.

Top Pressures start at depth = 0.00

```
        |      D1=0.00
        |
        |
        |
      ==|==    D2=14.00
        |
        |
        |      D3=48.20

        D1 - TOP DEPTH
        D2 - EXCAVATION BASE
        D3 - PILE TIP (20% increased, see EMBEDMENT Notes below)

   MOMENT BALANCE: M=0.00   AT DEPTH=42.50  WITH EMBEDMENT OF 28.50
   FORCE BALANCE: F=0.00   AT DEPTH=48.20  WITH EMBEDMENT OF 34.20

   The program calculates an embedment for moment equilibrium, then increase the
embedment by 20% to reach force equilibrium.
   A Balance Force=24.45 is developed from depth=42.50 to depth=48.20
   Total Passive Pressure = Total Active Pressure,    OK!

**********RESULTS**********

* EMBEDMENT Notes *
Based on USS Design Manual, fist calculate embedment for moment equilibrium, then
increased by 20 to 40 % to reach force equilibrium.
The embedment for moment equilibrium is 28.50
* The 20% increased embedment for force equilibrium is 34.20 (Used by Program)
The 30% increased embedment for force equilibrium is 37.06
The 40% increased embedment for force equilibrium is 39.91

Based on AASHTO 2002 Standard Specifications, fist calculate embedment for moment
equilibrium, then add safety factor of 30% for temporary shoring; add safety factor
of 50% for permanent shoring.
The embedment for moment equilibrium is 28.50
Add 30% embedment for temporary shoring is 37.06
Add 50% embedment for permanent shoring is 42.76

* BASED ON USS DESIGN MANUAL (20% increased), PROGRAM CALCULATED MINIMUM EMBEDMENT
= 34.20
TOTAL MINIMUM PILE LENGTH = 48.20

* MOMENT IN PILE (per pile spacing)*
Pile Spacing:  sheet piles are one foot or one meter; soldier piles are one pile.
Overall Maximum Moment = 119.41 at 31.46
```

report.out

Maximum Shear = 24.26
Moment and Shear are per pile spacing: 1.0 foot or meter

* VERTICAL LOADING *
Vertical Loading from Braces = 0.00
Vertical Loading from External Load = 0.00
Total Vertical Loading = 0.00

* DEFLECTION *
I (in4)/foot=419.90
Top deflection = 2.059(in)
Max. deflection = 2.059(in)

APPENDIX G

Steel Sheet Pile Design Memo

CIORBA GROUP | Consulting Engineers

PROJECT MEMO

TO: Lucas Carr PE, Geosyntec Consultants
Project Engineer

FROM: William Bakos, EI / Alex Durbak PE, SE

CHECKED BY: Brett Sauter PE, SE, Structural Group Manager

DATE: 6/28/2018

REFERENCE: Hennepin Sheet Pile Wall Design

PROJECT NO.: 20890.01

Ciorba Group engineers performed an independent calculation to verify the design of the sheet pile wall along the west side of the Old West Ash Pond which will be installed to allow for closure-by-removal of the Old West Polishing Pond as shown in the plans dated April 13, 2018.

DESIGN ASSUMPTIONS

Ciorba Group engineers take no exception to the assumptions which were used to develop earth pressures. The summary of parameters (attached) as provided by Geosyntec Consultants on June 15th, 2018 was utilized in the verification calculations. In the independent calculation, the upper 1-foot of soil embedment was neglected for passive resistance.

INDEPENDENT CALCULATION METHOD AND RESULTS

Ciorba Group engineers performed independent spreadsheet calculations to verify the validity of the designed embedment depth and sheet pile section for the wall using Coulomb theory and the free earth support method. The wall was analyzed for both the drained and undrained condition. The sheet pile wall has a safety factor for overturning of 1.3 for a temporary wall which was applied by dividing the passive pressure by 1.3. The allowable steel stress was taken as 30 ksi.

The independent calculation resulted in similar calculated pressures and maximum moment, embedment depth requirement, and required section modulus of sheet pile as that prepared by Geosyntec, however the independent calculated deflections were higher than those prepared by Geosyntec. The free earth support method typically overestimates deflection calculations and the deflections that Geosyntec calculated using the CivilTech Shoring program, which uses an empirical method, are considered more reasonable. The results of the independent calculations confirm that the sheet pile section NZ 26 and the embedment as shown on the prefinal plans prepared by Geosyntec are adequate.

Subject: Hennepin Earth and Hydrostatic Pressures for Sheet Pile Wall Design

Brett,

Below is a detailed summary of how we developed the earth pressures used for design and tables with the earth and hydrostatic pressures to be used for your design. All of this was pulled from the package Lucas provided to you earlier. Please feel free to reach out to me with questions.

Cross-section Section A-A' (Attachment A) was used for design. This is considered the critical cross section because it has the largest unsupported wall height and a relatively thick zone of alluvial silts and clays within the subsurface. The same subsurface stratigraphy, soil properties, and groundwater conditions used for the slope stability analyses at Section A-A' were used for the steel sheet pile (SSP) wall design. The groundwater table behind the wall was assumed to be at El. 451 ft; this is the elevation measured by existing piezometers and the approximate normal pool elevation in the Old West Polishing Pond (OWPP) and was used because the sheet pile wall was assumed to be impermeable. The groundwater table in front of the wall as assumed equal to the closure-by-removal ground surface in the OWPP (El. 440.4 ft), resulting in 10.6 ft of hydrostatic imbalance. The proposed buttress at Section A-A' was not included in the analysis, as this buttress will not be constructed until after closure-by-removal of the OWPP is complete.

All loads were assumed static, and both drained and undrained loading conditions were considered for the temporary scenario.

Assumptions used to develop earth pressures

- For undrained analyses (ϕ=0, c=su), it is possible to calculate negative active earth pressures using classic earth pressure theory equations (e.g., Coulomb). For these analyses, negative active earth pressures were resolved to zero;
- The sheet piles will be free to deflect normal to the plane of the wall and thus active earth pressures will develop;
- Lateral earth pressures were calculated following Coulomb theory;

- A wall-to-soil interface friction angle of 10° was applied for all interfaces;
- There is a 14° slope immediately upslope of the wall;
- For the silt and clay alluvium, a drained friction angle of 30°, representing the shear strength determined from CIU triaxial tests, was used for earth pressure calculations instead of the friction angle calculated from direct shear strength tests. This is because the base angle of the active and passive wedges will be non-horizontal and oriented in a manner similar to a triaxial compression test, rather than a direct shear test;
- Seepage below the sheet pile tip was neglected because the sheet piling extends through the low permeability silt and clay alluvium unit and the sheet pile is assumed to act as a hydraulic cutoff;
- For undrained analyses, it was assumed that the CCR material would behave drained. Excess pore pressures that may develop within the CCR are expected to dissipate more rapidly than the native materials and thus behave drained relative to the native materials. Furthermore, assuming the CCR behaves drained imposes a greater load on the SSP wall which conservatively models the CCR loading on the SSP; and
- Calculated active and passive earth pressures are unfactored.

1. EXECUTIVE SUMMARY

A geotechnical investigation was performed for the Old West Ash Pond (OWAP) and Old West Polishing Pond (OWPP) at the Hennepin Power Station, located in Hennepin, Illinois. The Power Station is owned and operated by Dynegy Midwest Generation, LLC.

The geotechnical investigation results suggest that construction dewatering is unlikely to be required for excavation of CCR during closure construction of the OWAP. Subsurface conditions encountered during test pit excavations were favorable, and unsaturated CCR was encountered within and at least five feet below the bottom of proposed excavations. However, phreatic levels within the CCR may vary and potentially increase seasonally, based on local precipitation, changes in the pool level in the Illinois River, and/or other factors. Stormwater should be carefully managed during closure construction to prevent ponding in excavations, which may lead to saturation of the CCR.

Fill placement in the western portions of the OWAP will occur over CCR that becomes saturated at approximately three feet below grade. Temporary subgrade stabilization measures, such as haul road construction or bridging lifts, may be required to provide equipment access in this area. However, construction dewatering is not anticipated to be required in this area as stormwater and subgrade stabilization measures will be specified to be carefully managed.

For the OWPP, the dewatering study found that the perimeter dikes and foundation soils have relatively low permeabilities. This suggests that groundwater inflows during closure-by-removal construction will be relatively low and can likely be managed using a system of shallow trenches and pumped sumps for dewatering. Haul roads and/or work platforms may be needed to facilitate equipment access into the OWPP during excavation.

Closure construction for both the OWAP and OWPP may be affected by flooding events on the adjacent Illinois River. If a flood event were to occur during construction, it may cause an increase in groundwater levels within the OWAP and OWPP and promote increased seepage or surface water inflows. This may require work stoppages until the flood event recedes.

Geotechnical information was also collected to support the final design of the sheet pile wall and support closure-induced settlement analyses. The data collected from these investigations is expected to be sufficient for final design. Deep borings to estimate the depth to and type of bedrock at the site were not successful due to difficult drilling conditions. However, a publicly-available log for a water well drilled approximately one-half mile from the site indicates shale bedrock at a depth of approximately 100 feet below the crest of the OWAP.

2. PROJECT BACKGROUND

The purpose of this geotechnical investigation was to collect geotechnical data to support the final closure design of the OWAP and OWPP at the Hennepin Power Station. The geotechnical investigation included:

- Test pits and piezometers to evaluate the need for construction dewatering and the feasibility of trenches for construction dewatering of CCR within the OWAP;
- Piezometers and pumping tests to estimate in-situ hydraulic conductivity of soils at the OWPP, for use in calculating excavation inflows;
- Borings to confirm subsurface stratigraphy along the sheet pile wall between the OWAP and OWPP, for completing final wall design;
- Deep borings to estimate the depth to and type of bedrock beneath the OWAP, for evaluating the cost and feasibility of a deep cutoff wall for groundwater remediation; and
- Laboratory testing to estimate the index properties, compressibility, and permeability of CCR and soil for estimating post closure settlements and excavation inflows; and
- Laboratory testing to estimate the undrained shear strength of foundation soils along the proposed sheet pile wall, for completing final wall design.

The methods, results, and general conclusions from the geotechnical investigation are discussed in **Section 3**.

3. GEOTECHNICAL INVESTIGATION

The geotechnical investigation included a field investigation (**Section 3.1**) and laboratory investigation (**Section 3.2**). Summarized subsurface conditions are provided in **Section 3.3** and the results of limited engineering analyses of pumping and recovery tests are provided in **Section 3.4**.

3.1 Field Investigation

3.1.1 Old West Ash Pond Dewatering Investigation

The goal of the test pits was to evaluate the feasibility of dewatering saturated CCR using open trenches. This type of dewatering can be simulated using test pits. The instrumented test pits were intended to allow for the evaluation of drawdown of the phreatic surface adjacent to the test pits.

Instrumented test pit locations were selected to evaluate subsurface conditions at areas of greatest proposed cut where CCR was expected to potentially be saturated during closure construction. The non-instrumented test pit locations were selected to evaluate the spatial variability of CCR conditions across the OWAP.

The field investigation for the OWAP included digging nine test pits (GS-T01 through GS-T09). Three of the test pits (GS-T01 through GS-T03) were instrumented with two temporary standpipe piezometers each, located 5 and 30 feet from the edge of the test pit (GS-P01 through GS-P06).

3.1.1.1 Piezometers

The piezometers were installed using a hollow-stem auger drill rig owned and operated by Roberts Environmental Drilling, Incorporated (REDI Drill) of Millstadt, Illinois on November 7, 2017. Geosyntec supervised the piezometer installation and logged the subsurface materials at each piezometer by examining drill cuttings.

The bottom of each piezometer was installed approximately 10 feet below grade. The piezometers were entirely within CCR materials. Each piezometer included a five-foot long 0.010-inch slotted polyvinyl chloride (PVC) screen, FilterSil® No. 1 sand pack, and hydrated bentonite chip seal. Each piezometer included a temporary surface completion consisting of a two-inch solid PVC riser with approximately three feet of stickup above grade. A vented well cap was installed on each piezometer, and groundwater in the piezometers was allowed to reach hydrostatic equilibrium with the surrounding CCR over an eight-day period prior to advancing test pits. Piezometer construction details are

provided in **Table 1**, piezometer locations are provided in **Figure 1** and piezometer construction logs are provided in **Appendix B**.

[1]Piezometer locations were surveyed by IngenAE, LLC on January 17, 2018. Horizontal coordinates are in the NAD83 datum and elevations are in the NAVD88 datum.

3.1.1.2 Test Pits

The test pits were advanced by a trackhoe owned and operated by Gensini Excavation, Incorporated of Princeton, Illinois on November 15 and 16, 2017 under Geosyntec's supervision. Prior to excavating the instrumented test pits, the water levels in the adjacent piezometers, located 5- and 30 ft from each test pit, were checked and nearly all were found to be essentially dry.

Each of the instrumented test pits (GS-T01 through GS-T03) was excavated to approximately 10 feet below grade without encountering saturated CCR, groundwater inflows, or other unstable conditions. The sides of the test pit excavations stood vertically and did not cave during test pit excavation. The non-instrumented test pits were also successful and encountered similar subsurface conditions as the instrumented test pits, except for test pits GS-T07 and GS-T08; saturated CCR was encountered at depths of 3.0 and 5.8 ft, respectively. Test pit GS-T05 encountered several isolated pockets of CCR, but the pockets were not observed to be laterally or vertically continuous. Test pits GS-T05, GS-T07, and GS-T08 were located in areas of planned fill rather than excavation.

After excavation, the test pits were left open for 24 hours to hours to evaluate groundwater inflows. Eight of nine test pits were dry at 24 hours; GS-T07 accumulated approximately 8 inches of standing water. All test pits were backfilled on November 16, 2017. Test pit excavation details are provided in **Table 2**, test pit locations are provided in **Figure 1**, photographs of the test pits are provided in **Appendix A**, and test pit logs are provided in **Appendix C**.

3.1.2 Old West Polishing Pond Permeability Investigation

The goal of the piezometer installation and testing was to collect data on soil types and permeability for use in estimating groundwater inflows during closure-by-removal excavation of the OWPP.

The field investigation for the OWPP included installing and sampling two piezometers (GS-P07 and GS-P08) down into foundation soils below the base of the proposed excavation. Instrumented pumping and recovery tests were performed on GS-P07, GS-P08, and existing piezometer HEN-P001.

3.1.2.1 Piezometers

The piezometers were installed on November 11, 2017 under Geosyntec supervision using the same hollow-stem auger drill rig and crew as the OWAP piezometers. The piezometers were continuously sampled during advancement, primarily using the Standard Penetration Test (SPT) (ASTM International, 2011) technique, although limited Shelby tube (ASTM International, 2015) samples were also collected for laboratory permeability testing of the foundation clay beneath the OWPP dikes.

The piezometer borings were advanced until native soils were encountered and then each piezometer was constructed using a 10-foot long 0.010-inch slotted PVC screen, FilterSil® No. 1 sand pack, and hydrated bentonite chip seal. Both piezometers included a temporary surface completion consisting of a two-inch diameter solid PVC riser with approximately three feet of stickup above grade. A vented well cap was installed on each piezometer and the piezometers were allowed to reach hydrostatic equilibrium with the surrounding soil for six days prior to performing the groundwater recovery tests.

Piezometer construction details are provided in **Table 3**, piezometer locations are provided in **Figure 1**, and piezometer construction logs are provided in **Appendix B**.

Table 3 – Old West Polishing Pond Piezometer Construction Details

Piezometer ID	Northing[1] (ft)	Easting[1] (ft)	Surface Elevation[1] (ft)	Total Depth (ft)	Screen Depths (ft)	Filter Pack Depth (ft)	Seal Depth (ft)	Casing Stick-Up (ft)
GS-P07	1688524	2526764	459.2	20.0	9.7 - 19.7	9.0 - 20.0	0.0 - 9.0	3.0
GS-P08	1688312	2527027	458.7	18.3	8.0 - 18.0	7.0 - 20.3	0.0 - 7.0	3.0

[1]Piezometer locations were surveyed by IngenAE, LLC on January 17, 2018. Horizontal coordinates are in the NAD83 datum and elevations are in the NAVD88 datum.

3.1.2.2 Pumping and Recovery Testing

Instrumented pumping and recovery tests were performed by Geosyntec on November 16, 2017. Tests were performed at piezometers GS-P07, GS-P08, and HEN-P001. The pumping piezometers were instrumented with stand-alone pressure transducers (In-Situ Level TROLLs 700®) and data loggers to collect water level measurements during the pumping tests. A Proactive Hurricane XL pump was placed at the bottom of each piezometer casing and a pressure transducer was placed approximately one foot above the pump. Manual groundwater level measurements were also collected during pumping to verify pressure transducer data.

Water level measurements were collected by the dataloggers at approximately one-minute time intervals during pumping and recovery. The piezometers were pumped at rates between 1.68 L/min (0.5 gallons per minute [gpm]) to 3.04 L/min (0.8 gpm) for durations between 3.5 and 21 minutes, as necessary to pump most water out of the piezometers. Measurements were collected during well recovery for durations between approximately 30 and 182 minutes, as necessary for the water level in the piezometer to rebounded to within 0.5 feet of the pre-pumping water level.

Photographs of the recovery testing setup are provided in **Appendix A**.

3.1.3 Old West Ash Pond Sheet Pile, Slurry Wall, and Soil Compressibility Investigation

The field investigation program for the OWAP included six borings. Two borings were drilled in the OWAP (GS-B01 and GS-B02) for collecting samples of CCR and alluvial clay for consolidation testing and for evaluating the depth and type of bedrock for potential design of a slurry containment wall. Four borings (GS-B03 through GS-B06) were drilled along the alignment of the sheet pile wall to assess subsurface conditions and support final design of the wall.

The geotechnical borings were advanced between November 7 and 11, 2017, using a drill rig owned and operated by REDI Drill of Millstadt, Illinois. Geosyntec supervised the drilling and logged the subsurface materials at each boring. The borings were advanced using hollow-stem augers and mud-rotary techniques.

Table 4 – Old West Ash Pond Boring Details

Boring ID	Northing[1] (ft)	Easting[1] (ft)	Surface Elevation[1] (ft)	Total Depth (ft)
GS-B01	1688362	2527555	460.9	31.0
GS-B02	1689138	2528829	464.6	9.0
GS-B03	1688617	2527230	460.1	55.5
GS-B04	1688435	2527245	459.1	45.5
GS-B05	1688777	2527235	459.2	20.5
GS-B06	1688347	2527250	458.4	21.0

[1]Boring locations were surveyed by IngenAE, LLC on January 17, 2018. Horizontal coordinates are in the NAD83 datum and elevations are in the NAVD88 datum.

Several problems were encountered in the drilling of boring GS-B01, including:

- Difficulties in reaching the boring location with the driller's service truck,
- Significant loss of drilling fluid into pervious gravel foundation soils, and
- Refusal on cobbles and/or boulders at 30.5 ft below ground surface (bgs).

Based on these difficulties, Geosyntec and Dynegy jointly agreed to abandon the collection of deep boring data at the site. Bedrock borings, if deemed necessary at a later date, should be advanced using another drilling technology, such as sonic drilling, to penetrate the cobbles/boulders.

Boring details are provided in **Table 4**, boring locations are shown in **Figure 1**, and boring logs are provided in **Appendix D**.

3.2 Laboratory Investigation

Laboratory testing was performed on samples of soil and CCR to evaluate the index properties, permeability, strength, and compressibility. The laboratory test program included:

- 8 Atterberg limits tests in accordance with ASTM D4318 (ASTM International, 2017)
- 8 Grain size analyses in accordance with ASTM D422 (ASTM International, 2007)
- 4 Grain size analyses with hydrometer testing in accordance with ASTM D422 (ASTM International, 2007)
- 24 Natural moisture content tests in accordance with ASTM D2216 (ASTM International, 2010)
- 1 Specific gravity test in accordance with ASTM D854 (ASTM International, 2014)
- 3 Unconsolidated-undrained triaxial compression tests in accordance with ASTM D2850 (ASTM International, 2015)
- 4 Incremental consolidation tests in accordance with ASTM D2435 (ASTM International, 2011)
- 6 Flexible wall hydraulic conductivity tests in accordance with ASTM D5084 (ASTM International, 2016)

Summarized laboratory testing results, and individual laboratory test results sheets, are provided in **Appendix E**.

3.3 Summary of Subsurface Conditions

3.3.1 Old West Ash Pond CCR

The CCR within the Old West Ash Pond can generally be classified as a cohesionless silt (ML) or silty sand (SM) based on the laboratory testing results. The CCR was found to be predominantly fly ash, with only limited amounts of bottom ash and slag present. The fines content of the material ranged from 87 to 95 percent, and the vertical permeability ranged from 6.7×10^{-6} to 1.4×10^{-5} centimeters per second (cm/sec), with a geometric mean value of 1.2×10^{-5} cm/sec.

Data from the test pits, when combined with existing boring and piezometer data from the OWAP (AECOM, 2015), (Civil and Environmental Consultants, 2017) indicated that CCR within the OWAP is generally unsaturated to at least 10 ft below grade over the eastern portions of the OWAP. Towards the western portions of the OWAP, the CCR became saturated at approximately three to seven feet below grade around the perimeter of the pond. These conclusions are based on a limited amount of piezometric data within the CCR and correspond to a relatively low pool elevation on the adjacent Illinois River[1]. Phreatic levels may change seasonally based on local precipitation and/or fluctuations in the pool level in the adjacent Illinois River. Additional piezometric data will be collected by Dynegy from piezometers screened within CCR and installed in 2017 by this study and others (Civil and Environmental Consultants, 2017) and will provide additional information on fluctuations in phreatic levels.

Phreatic levels likely decline from west to east because the eastern side of the OWAP is underlain by permeable sand and gravel that allows for vertical drainage of surface water into the foundation soils. The western side of the OWPP is underlain by low-permeability silt and clay; this impedes the flow of surface water into the foundation soils. Additionally, the surface grade of the OWAP decreases in elevation from east to west; this may result in temporary ponding of surface water on the surface of the OWAP after rainfall events.

3.3.2 Old West Polishing Pond Dike and Foundation Soils

Data from Geosyntec's piezometers (GS-P07 and GS-P08), when combined with existing boring and piezometer logs (AECOM, 2015), indicates that the OWPP perimeter dike was constructed in two stages. The first stage (original dike) was constructed on the alluvial foundation soils and a sand and gravel dike raise was constructed over the original dike at a later date.

The sand and gravel dike raise was present from the top of the dike to depths ranging from 6 to 10 ft, and consists of a loose to very dense coarse-grained soils including poorly-graded gravel (GP), clayey gravel (GC), poorly-graded sand (SP), silty sand (SM), and

[1] The pool level at the time of the field exploration was approximately El. 443 ft on the La Salle, IL gauging station (United States Army Corps of Engineers, 2018), located approximately 12 miles upriver from the Hennepin Power Station. The historic normal stage for November is approximately El. 442 ft. Annual historic normal stages vary from approximately El. 447 ft in May to El. 441 ft in October. During 2017, the maximum pool level recorded by the La Salle, IL gauging station was El. 457 ft on May 2nd, and flood stage is El. 450 ft. All elevations recorded by the La Salle, IL gauging station are in the NGVD29 datum, and are approximately 0.2 ft higher than the NAVD88 datum at the Hennepin Power Station.

clayey sand (SC) with a trace of coal fragments and slag. One sieve analysis was performed and measured a fines content of 24%.

The original dike was present between the bottom of the sand and gravel dike raise to depths ranging from 15 to 16 ft. It consisted of a mixture of medium dense to very stiff silt (ML) and silty sand (SM), with intermingled coal fragments and boiler slag. Fines contents of this material were measured to range from 20 to 61%, with a mean value of 48%.

Alluvial foundation materials were present between the bottom of the original dike and consist of soft lean clay (CL) and fat clay (CH) with fine contents ranging from 64 to 96%. Two flexible-wall hydraulic conductivity tests were performed on this material, and measured vertical hydraulic conductivities of 4.5×10^{-8} cm/sec and 7.5×10^{-8} cm/sec, with a geometric mean value of 6.0×10^{-8} cm/sec. The mass hydraulic conductivity of the alluvial foundation materials may be higher than the laboratory measurements from individual specimens. Sand and gravel alluvium was found to be present immediately below the cohesive alluvial foundation materials.

3.3.3 CCR and Alluvial Clay Compressibility

CCR within the OWAP had relatively low compressibility based on two consolidation tests performed on the material, with recompression indices (C_r) of 0.025 and 0.010. The CCR maximum past pressure (P'_p) of the CCR was estimated to be 1.9 and 1.0 tons per square foot (tsf); this indicates apparent over consolidation of the CCR.

Two consolidation tests were performed by Geosyntec on samples of alluvial clay collected from beneath the OWAP and one test was performed by AECOM in 2015 (AECOM, 2015). One of the Geosyntec tests (GS-B04 from 33.5 to 35.5 ft) was found to be highly compressible. The sample was noted by the testing laboratory as likely containing organic material, and is therefore considered an outlier. The remaining consolidation tests performed by Geosyntec and AECOM measured recompression indices of 0.03 for both samples and compression indices of 0.26 and 0.35. The maximum past pressure of the alluvial clay was measured to be 0.7 and 2.1 tsf, indicating over consolidation ratios ranging from approximately 1 to 2.

3.3.4 Sheet Pile Wall Alignment

Four borings were drilled along the sheet pile wall alignment. Two deep borings (GS-B03 and GS-B04) were drilled to collect information on the material interfaces and strengths along the maximum section of wall alignment, while two shallow borings (GS-

B05 and GS-B06) were drilled near the north and south limits of the wall to confirm the limits of CCR materials along the wall alignment.

Deep borings GS-B03 and GS-B04 borings encountered CCR to maximum depths of 19.0 and 18.5 feet, and alluvial clay from the bottom of the CCR to maximum depths of 48.5 and 38.5 feet. Sand and gravel alluvium was encountered immediately below the alluvial clay. The deep borings were terminated within the sand and gravel alluvium at depths of 55.5 and 45.5 ft, respectively.

Shallow boring GS-B05, drilled at the north end of the proposed wall, did not encounter CCR material. Shallow boring GS-B06, drilled at the south end of the proposed wall, only encountered CCR between five and nine feet in depth.

Undrained shear strengths from unconsolidated-undrained triaxial compression testing on three samples of alluvial clay were found to be approximately 460 psf at a depth of 25 feet and 870 psf at a depth of 34 feet. The measured shear strengths are consistent with a normally-consolidated alluvial clay.

3.3.5 Depth to Bedrock

The planned bedrock borings were not successful, as discussed in **Section 3.1.3**. A drilling log for a water well installed approximately one-half mile southwest of the OWPP, within the Illinois River floodplain, was obtained (Illinois State Geological Survey, 2017). This log indicates shale bedrock at a depth of 83 feet, overlain by gravel and sand. Boulders were noted between depths of 4 to 18 feet and 26 to 33 feet. This water well represents the best currently-available bedrock data for the site, and is provided in **Appendix F**.

3.4 Engineering Analysis – Old West Polishing Pond

The hydraulic conductivity and transmissivity of the OWPP original dikes were estimated using the instrumented pumping and recovery test data. The dikes were modeled as an unconfined, unconsolidated water-bearing unit, with a boundary layer of alluvial clay foundation materials at a depth of approximately 16 ft. The thickness of the water-bearing unit was measured from the static water level before pumping to the top of the alluvial clay foundation materials.

Data from the instrumented pumping and rebound tests were analyzed using AQTESOLV, Version 4.50 (HydroSOLVE Inc, 2002) software using three analytical methods including (Theis, 1935), (Jacob, 1946), and (Neuman, 1974). Unconfined water table corrections were used for each analytical method.

Based on the analysis, the hydraulic conductivity of the OWPP original dikes ranged from approximately 2.6×10^{-6} cm/sec at GS-P08 to 2.9×10^{-5} cm/sec at GS-P07, with a geometric mean value of 8.2×10^{-6} cm/sec for all piezometers. These values are consistent for silty materials with relatively high fines contents. A summary of the results is provided in **Table 5**.

Table 5 – Old West Polishing Pond Hydraulic Conductivity Results

Well ID	Water-Bearing Unit Thickness (ft)	Water-Bearing Unit Type	Method	Hydraulic Conductivity (cm/sec)
GS-P07	6.5	Unconfined	Theis (1935)	4.6E-05
			Cooper-Jacob (1946)	9.5E-06
			Neuman (1974)	5.8E-05
			Geometric Mean	2.9E-05
GS-P08	6.5	Unconfined	Theis (1935)	2.1E-06
			Cooper-Jacob (1946)	3.0E-06
			Neuman (1974)	2.8E-06
			Geometric Mean	2.6E-06
HEN-P001	4	Unconfined	Theis (1935)	6.0E-06
			Cooper-Jacob (1946)[1]	1.1E-02
			Neuman (1974)	7.6E-06
			Geometric Mean	6.7E-06

[1]Value is assumed to be an outlier and is not considered in the mean hydraulic conductivity.

4. CONCLUSIONS

Data collected from the geotechnical investigation will be used to complete final design of the OWAP and OWPP closure. Preliminary conclusions based on these data include:

- Phreatic levels in the CCR in the OWAP were at least five feet below the bottom of proposed excavation grades. In areas where fill will be placed, phreatic levels ranged from 3 to over 10 feet below grade. Small, isolated, saturated pockets of CCR were encountered above the phreatic surface in one test pit but were not found to be laterally or vertically continuous.
- Phreatic levels in the CCR may vary seasonally due to local precipitation and/or fluctuations in the adjacent Illinois River pool level. The lowest cut elevation in the OWAP is approximately El. 458 ft; this is approximately 8 ft above flood stage on the adjacent Illinois River (El. 450 ft) and approximately 1 ft above the maximum Illinois River pool level recorded during 2017 (El. 457 ft). Temporary work stoppages may be required if flooding occurs on the adjacent Illinois River, as the flooding could saturate CCR above levels observed during the field exploration.
- The presence low-permeability clay underneath the OWAP may result in perched phreatic conditions within the OWAP if high local rainfall occurs. While these conditions were not encountered within areas of proposed excavation during the field exploration, they could occur during construction as a result of local precipitation.
- Excavations within the OWAP can likely be completed using conventional earthwork equipment, without the need for construction dewatering. However, stormwater will need to be carefully managed during construction to prevent temporary ponding within excavations, which may saturate the surrounding CCR. Excavations should include provisions to temporarily direct stormwater into sumps or shallow basins for prompt removal by pumping. Stormwater, if allowed to pond within the excavations, may destabilize the excavations.
- Fill placement within the western portions of the OWAP may occur over CCR that is saturated at three feet or less below the ground surface. Temporary subgrade stabilization may be required to support equipment access in these areas. Methods for stabilization may include the construction of access roads or placement of bridging lifts to allow for equipment access.
- Closure-by-removal excavation of the OWPP can likely be completed using a system of shallow trenches and pumped sumps to control excavation inflows. Excavation inflow quantities will be estimated during final design. Temporary

subgrade improvements, including haul roads and/or work platforms, may be required to allow for equipment access into the OWPP during excavation.

- Closure-by-removal excavation of the OWPP may be affected by flood events on the adjacent Illinois River. The rim elevation of the excavation will be approximately El. 450 ft, which is equal to the Illinois River flood stage. The bottom elevation of the excavation is approximately equal to the mean annual historic normal river elevation of El. 443 ft. Temporary work stoppages may be required if a flood event occurs on the Illinois River during construction, and such a flood event may fill the excavation with water through either increased seepage inflows or overtopping. Careful staging of the excavation during should be performed to remove CCR from inside of the excavation prior to removing the perimeter dikes to reduce the potential of floodwater contact with CCR. The existing crest elevation of the OWPP perimeter dikes is approximately El. 459 ft; this is approximately nine feet above flood stage on the Illinois River.
- Bedrock at the site is anticipated to be present approximately 100 ft below grade, but the depth was unable to be verified at the OWAP. If bedrock data is deemed necessary at a later date, it should be collected using a drilling technique that can penetrate through boulders and cobbles, such as sonic drilling.

Note that the results of the investigation are applicable to the conditions at the time of the investigation and future results may be different as environmental and climate conditions change.

5. LIMITATIONS

The conclusions and recommendations presented in this report are based on a limited subsurface investigation program performed by Geosyntec and others. Subsurface conditions may vary between exploration locations. Additionally, observed phreatic conditions within CCR and foundation soils may change seasonally based on precipitation, levels in the Illinois River, and other factors.

Information provided by Dynegy and/or their contractors was used in the preparation of this report. Geosyntec has assumed that such information is correct and has not verified and is not responsible for the accuracy of such provide information.

TEST PIT NUMBER GS-T07

Geosyntec consultants

CLIENT Dynegy Midwest Generation, LLC
PROJECT NAME Dynegy - Hennepin Power Station
PROJECT NUMBER CHE8356
PROJECT LOCATION Hennepin, Illinois
DATE STARTED 11/15/2017 **COMPLETED** 11/16/2017
GROUND ELEVATION 455.4 ft. **HOLE SIZE** 4.5' x 10'
CONTRACTOR Gensini Excavation, Inc.
NOTES Test pit logged from excavation spoils.
EQUIPMENT CAT Excavator
GWL AT TIME OF EXCAVATION 3 ft
EXCAVATION METHOD Vertical trenching
GWL AT END OF EXCAVATION Dry
LOGGED BY D. Mateas **CHECKED BY** L. Carr
GWL AFTER EXCAVATION 4.2 ft at 10:35 AM on 11/16/17

ELEVATION (ft)	DEPTH (ft)	GRAPHIC LOG	MATERIAL DESCRIPTION	SAMPLE TYPE NUMBER	RECOVERY/ ATTEMPTED (in)	BLOW COUNTS (N VALUE)	POCKET PEN. (tsf)	TORVANE (tsf)	PID (ppm)	MOISTURE CONTENT (%)	ATTERBERG LIMITS: LIQUID LIMIT	ATTERBERG LIMITS: PLASTICITY INDEX
455	0		**SILT** (ML): dark gray (10YR 4/1), nonplastic, soft, moist with lenses of saturated material [FLY ASH]									
	5		changes to very soft, saturated at 3 ft.									
450			Note: (1) End of test pit at 5 ft. bgs (2) Test pit is located at 1688711 ft. N and 2527343 ft. E. Coordinates are in NAD83 (IL West) datum and elevations are in NAVD88 datum. (3) Groundwater levels at time of excavation were estimated based on ash/soil moisture. Groundwater levels after excavation were measured.

Notes:

[1]Shelby tube samples are denoted by "T". Standard Penetration Test samples are denoted by "SPT"

[2]USCS classifications are based on field classifications for soil samples where only a Atterberg limit or only a sieve analysis were performed.

[3]Samples determined to be noNplastic are denoted by "NP"

[4]Failure is defined as peak deviator stress ($s_1 - s_3$), limited to 15% axial strain

[5]Consolidation parameters were estimated by Geosyntec using the Casagrande method

[6]Sample 9 from boring BS-B04 was noted by the laboratory as likely having a significant organics content, which likely resulted in the high compressibility of this sample.

[7]Samples where a hydrometer was not perfumed are denoted by "ND"

Project Name:	Dynergy Hennepin West Ash Ponds		
Project Location:	Hennepin, IL		
GTX #:	GTX-307367		
Start Date:	12/15/2017	Tested By:	jm
End Date:	12/20/2017	Checked By:	mcm
Boring	GS-B01	Test #: K1	
Sample #:	3		
Depth:	5-7 ft		
Visual Description:	Moist, dark gray silty sand (ASH)		

Hydraulic Conductivity of Saturated Porous Materials Using a Flexible Wall Permeameter by ASTM D5084 Increasing Tailwater

Sample Type:	Intact	Permeant Fluid:	de-aired tap water
Orientation:	Vertical	Cell #:	P2

Sample Preparation: Extruded from tube, cut, trimmed and placed into permeameter at as-received density and moisture content. Moisture content determined at 60°C for ash.

Re: 35 IAC 845.220(a)(9) Certification Statement
Hennepin Power Plant; West Ash Pond (IEPA ID # W1550100002-01-03)

Dear Mr. Darin LeCrone:

For the above-refenced CCR surface impoundments and in accordance with 35 IAC 845.220(a)(9), Dynegy Midwest Generation, Inc. certifies that the public notification and public meetings required under 35 IAC 845.240 were completed. Please find enclosed both the public meeting summary and listserv.

Sincerely,
Dynegy Midwest Generation, Inc.

Dianna Tickner, PE, PMP
Senior Director, Demolition and Decommission

Hennepin Public Meeting Summary, April 8, 2025

On March 9, 2025, Dynegy Midwest Generation, LLC ("Dynegy") made available to the public its proposed plans to implement corrective action at the previously closed West Ash Pond System (WAPS) located at the Hennepin Power Plant. On Tuesday, April 8, 2025 Dynegy held in-person public meetings at 3:00 pm and 5:00 pm at the AmericInn Lodge & Suites in Princeton, IL to present its decision-making process. A discussion of the corrective measures assessment and corrective action alternatives analysis, including an objective comparison of pros and cons and projected groundwater impacts for each of the alternatives, was presented at these meetings. During the question-and-answer portion of the meetings, the public asked questions relating to the proposed remedial measures which the company addressed. As required by Section 845.240(g), this document provides a general summary of the issues or comments raised by the public relating to the closure, a summary of the company's responses to those issues or comments, and a summary of any revisions or changes made to the proposed corrective action as a result of issues and comments raised by the public. All questions asked during the meeting were addressed. This document also provides as required by 845.240(f)(3), written responses to subsequent questions posed following the meeting.

Issue/Topic		Summary of Response Provided at Meeting	Additional Written Response
1.	Closure Method	The purpose of the current public meeting is to discuss the corrective action evaluation for groundwater remediation at the West Ash Pond System. The West Ash Pond System was previously closed and capped in 2020 with IEPA approval. The final closure system meets the cover design requirements of Part 845 and Federal Part 257. The approved closure method included protecting the ash pond from flood events, such as armoring the pond with rip rap for protective measures.	The final closure system includes riprap armoring on the exterior dikes adjacent to the Illinois River. The riprap armoring was designed based on calculated floodwater velocities. No adverse affects to the completed closure have been observed.
2.	Groundwater Impacts and Monitoring	A risk assessment confirmed that the ash pond is not adversely impacting human health and the environment; specifically the ash pond is not negatively impacting the river habitat and does not present a risk to river users. No potable water wells are impacted. The corrective action will reduce, to the maximum extent feasible, further releases and minimize further migration of CCR-derived constituents in groundwater until	

		the groundwater quality standards are achieved. Adaptive site management action will be taken if the remedy performance does not correspond with the expected performance. Groundwater is required to be monitored quarterly for a minimum of 30 years beginning after closure to ensure conditions are as anticipated. Groundwater monitoring will continue until groundwater quality standards are met.	
3.	Corrective Action Plan	Corrective action will consist of supplementing the completed source control (IEPA approved ash pond closure) through the installation of a vertically- and laterally-continuous, permanent, and low-permeability deep cutoff wall that will extend from the perimeter dikes of the West Ash Pond System into low-permeability bedrock beneath. This will result in the CCR within the West Ash Pond System being physically isolated from the environment on all sides by a permanent barrier, including the final cover system on the surface, the cutoff wall laterally, and competent shale bedrock below the ash pond. The proposed cutoff wall would prevent impacts from high river elevations. Cutoff walls are widely used and a common technology used for corrective action. Additional information and drawings are provided in the draft corrective action plan previously posted on Dynegy's publicly accessible website (noted below).	There is no evidence that bentonite clay cutoff walls degrade or "wear out" over time, due to the material being a blend of natural, inert, soil components. The chemicals of concern at West Ash Pond System are inorganic and do not affect soil properties or permeability of the bentonite mixture that will be utilized in the cutoff wall. Upgradient groundwater monitoring has not detected any chemicals of concerns that would impact the performance of the cutoff wall. The surrounding soils vary from clays to sands, and are compatible with the cutoff wall. The target hydraulic conductivity for the cutoff wall will be $1x10^{-7}$ cm/sec. This is approximately 120,000 times (5 orders of magnitude) lower than that of the surrounding aquifer materials (1.2×10^{-2} cm/sec for the gravel deposits). This will result in the wall having an appropriately lower hydraulic conductivity to function as a lateral barrier. During construction of the deep cutoff wall portion of the remedy, Dynegy will

			implement a construction quality control and quality assurance continual monitoring and testing of the actual slurry materials to verify that the as-installed deep cutoff wall will perform as in accordance with the proposed design. Additional information on this QA/QC program will be added to the Construction Permit Application for the WAPS.
4.	Working with IEPA	Dynegy has met all the required Part 845 deadlines for corrective action and public meeting notification. Prior closure of the West Ash Pond System was done with approval from IEPA. Dynegy has submitted an operating permit application under Part 845 in 2021. No permit has been issued yet.	
5.	More Information	Additional information about the items discussed in this Public Meeting can be found online. Data and documents for compliance with the Illinois CCR Rule: www.luminant.com/ccr/illinois-ccr/	

In accordance with 845.240(f)(4), a list of people who requested to be added to the IEPA Listserv from the Hennepin public meeting held on April 8, 2025, are as follows:

Re: 415 ILCS 5/22.59(b)(4) Certification Statement
Hennepin Power Plant West Ash Pond (IEPA ID # W1550100002-01-03)

Dear Mr. Darin LeCrone:

For the above-refenced CCR surface impoundments and in accordance with 415 ILCS 5/22.59(b)(4), Dynegy Midwest Generation, LLC certify that all contractors, subcontractors, and installers utilized to construct, install, modify, or close a CCR surface impoundment will be participants in a training program that is approved by and registered with the US Department of Labor's Employment and Training Administration and that includes instruction in the following: erosion control, environmental remediation, operation of heavy equipment and excavation.

Sincerely,
Dynegy Midwest Generation, LLC

Dianna Tickner
