Re: Illinois Power Generating Company - Newton Power Plant Primary Ash Pond (ID No. W0798070001-01)

Pursuant to Illinois Power Generating Company (IPGC) is hereby submitting this assessment of groundwater corrective measures for Newton Power Plant Primary Ash Pond to satisfy the following provisions:

- 35 I.A.C. 845.660 (Assessment of Corrective Measures), and
- 35 I.A.C. 845.650(d) (Characterization of Nature and Extent)

Along with this letter, these plans will be posted to Luminant's publicly accessible internet site: www.luminant.com/ccr/illinois-ccr/.

If you have any questions regarding this submittal, please contact Phil Morris at 618-343-7799 or phil.morris@vistracorp.com.

Sincerely,

Phil Morris

1. INTRODUCTION

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has developed this assessment of groundwater corrective measures on behalf of Illinois Power Generating Company (IPGC) to assist in the compliance with the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845 Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments. This assessment applies specifically the coal combustion residuals (CCR) unit referred to as the Primary Ash Pond (PAP) at the Newton Power Plant (NPP), also referred to as Vistra identification (ID) number (No.) 501, Illinois Environmental Protection Agency (IEPA) ID No. W0798070001-01, and National Inventory of Dams (NID) No. IL50719. This report addresses content requirements specific to 35 I.A.C. § 845.660 (Assessment of Corrective Measures) for exceedances of lithium, sulfate, and total dissolved solids (TDS) at the PAP.

1.1 Source Control and Residual Plume Management

IPGC intends to initiate significant source control and residual plume management efforts as part of the PAP closure, as documented in the Final Closure Plan and Construction Permit Application that were submitted to IEPA in July of 2022 (IPGC, 2022). The proposed closure exceeds the minimum Closure Performance Standards listed in 35 I.A.C § 845.750. The closure will include removing free liquids in accordance with the performance standard in 35 I.A.C § 845 and maintaining that condition during the closure construction period. The closure will reduce the hydraulic head that can force leachate into subsurface soils and is the mechanism that can drive risk (United States Environmental Protection Agency [USEPA], 2015a, p. 21342):

> *EPA's risk assessment shows that the highest risks are associated with CCR surface impoundments due to the hydraulic head imposed by impounded water. Dewatered CCR surface impoundments will no longer be subjected to hydraulic head so the risk of releases, including the risk that the unit will leach into the groundwater, would be no greater than those from CCR landfills.*

The PAP will be closed using a consolidate-and-cap approach consisting of excavating nearly 2 million cubic yards of CCR and placing it in a consolidated CCR footprint at an elevation greater than 5 feet above the uppermost aquifer (UA). The consolidated CCR will be covered with an alternate geomembrane final cover system having performance that exceeds the 35 I.A.C §845.750(c)(2) minimum final cover requirements. The proposed source control is predicted to reduce water flux into and out of the PAP by 94% and allow the groundwater protection standards (GWPS) to be achieved within approximately 20 years (Ramboll, 2022). These source control activities will serve as the primary groundwater corrective measure at the PAP. The potentially feasible corrective measures presented herein are intended to be supplementary to the primary source control and are intended to serve as management measures to address any residual plumes that remain after completion of source control.

Attachment A includes summary figures from the Construction Permit Application that show the proposed final source control and primary corrective action.

1.2 Adaptive Site Management

Adaptive site management strategies will be employed as an integral part of ongoing corrective action at the PAP. The adaptive site management approach will allow timely incorporation of new

site information over the closure and post-closure life cycle of the PAP to ensure the achievement of the GWPS. The adaptive site management approach is proposed to expedite progress toward meeting the GWPS while acknowledging uncertainties, such as the persistence of current groundwater flow directions and flux quantities and potential related changes in geochemical conditions. A structured decision-making process and explicitly planned iterations between the implemented corrective measures and monitoring results will ensure that remediation is occurring. System performance and the condition of the residual plume will be monitored as the corrective measure(s) selected through the 35 I.A.C. § 845.710 Corrective Action Plan (CAP) process are implemented to supplement the source control measures described above. If the groundwater concentrations do not decrease consistent with the modeling prediction, the adaptive site management approach will facilitate timely modifications or enhancements to the corrective measure(s), as needed in accordance with 35 I.A.C. § 845.680(b). This approach will be employed to provide continuous improvement to the PAP groundwater remediation in response to new site information and/or the performance of the selected corrective measure(s).

The planned adaptive site management strategies are generally consistent with National Research Council, Interstate Technology & Regulatory Council (ITRC) and USEPA methodologies developed to address sites with long remediation times and high levels of uncertainty regarding the remedial actions necessary to achieve final and protective remediation goals (USEPA, 2022). The elements of the proposed adaptive site management strategy at the PAP will be responsive to the changing conditions associated with pond closure and performance of the selected corrective measure(s) and will include the following:

1. Implementing the groundwater corrective measure(s) selected as part of the CAP for the current conditions at the PAP. The selected corrective measures may include a combination of the technologies presented in this Corrective Measures Assessment (CMA).

2. Establishing both the absolute remedial objective and functional (interim) goals to monitor progress toward the remedial objective. Achieving the GWPS for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary is the remedial objective for the PAP. Specific functional goals will be developed as part of the CAP process. The functional goals will be measurable thresholds for future action and may include short-term or technology-specific objectives and triggers. Functional goals may vary for different locations, CCR constituents or other site-specific considerations (ITRC, 2017) and will serve as benchmarks for comparison to ongoing groundwater monitoring at the PAP.

3. Ongoing groundwater monitoring at the PAP will continue throughout the implementation of source control and residual plume management activities. Post-closure monitoring will continue for a period of at least 30 years, in accordance with 35 I.A.C. § 845.780(c). A comprehensive groundwater monitoring plan (GMP) will be developed as part of the CAP process in accordance with 35 I.A.C. § 845.670 and 35 I.A.C. § 845.220(c)(4). The GMP will include the functional goals and proposed action levels.

4. Groundwater monitoring information will be used to guide decisions regarding whether progress toward the remedial goal is advancing as expected and/or whether additional actions may be needed to achieve the remedial objective, in conjunction with IEPA, as required by 35 I.A.C. § 845.680(b).

2. SITE INFORMATION

The NPP is located in Jasper County in the southeastern part of central Illinois, approximately 7 miles southwest of the town of Newton. The PAP is located in Section 26 and the western half of Section 25, Township 6 North, Range 8 East. The PAP is located south of the power plant and situated in a predominantly agricultural area (**Figure 2-1**). The PAP is surrounded by Newton Lake on the west, south, and east (**Figure 2-2**). Beyond the lake is additional agricultural land.

The NPP's sole CCR surface impoundment (SI), the PAP, was constructed in 1977 and has a design capacity of approximately 9,715 acre-feet. The PAP is an unlined CCR SI with a surface area of 404 acres which currently receives bottom ash, fly ash, and low-volume wastewater from the plant's two coal-fired boilers. The PAP is operated per National Pollutant Discharge Elimination System (NPDES) Permit IL0049191, Outfall 001. A construction permit application for the closure of the PAP (*e.g.,* source control) was submitted to IEPA on July 28, 2022 (IPGC, 2022); permit approval is pending at this time.

2.1 Conceptual Site Model

Significant site investigation has been completed at the NPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the PAP has been well characterized and detailed in the Hydrogeologic Site Characterization Report (Ramboll, 2021), which was prepared to comply with the requirements specified in 35 I.A.C. § 845.620 and expands upon the Hydrogeologic Monitoring Plan (Natural Resource Technology, an OBG Company [NRT/OBG], 2017). The conceptual site model (CSM) is presented below.

Quaternary deposits in the Newton area consist mainly of diamictons and outwash deposits that were deposited during Illinoian and Pre-Illinoian glaciations (Lineback, 1979; Willman et al., 1975). The unconsolidated deposits include the following units (beginning at the ground surface):

- **Upper Drift (UD)/ Potential Migration Pathway (PMP):** The upper drift (UD) is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member. The Peoria Silt and Sangamon Soil units are present within the PAP at thicknesses up to approximately 46 feet, as measured in APW15, and range from 3 to 46 feet thick as observed in APW05 and APW10 (Ramboll, 2021). The hydraulic conductivity of this unit, calculated from field hydraulic test data from monitoring wells screened between 8 and 36 feet below ground surface (bgs), was observed to range from 2.4×10^{-6} to 6.1×10^{-5} centimeters per second (cm/s) with a geometric mean of 1.3×10^{-5} cm/s (Rapps Engineering and Applied Science [Rapps], 1997).
  - **Hagarstown Member/PMP**: The Hagarstown Member consists of the discontinuous, sandier deposits of the UD where present and overlies the Vandalia Till. Where present, the sandy deposits of the Hagarstown are generally less than 2 feet thick, with a maximum encountered thickness of approximately 6.9 feet at APW18 (Ramboll, 2021). Results of field hydraulic conductivity tests in wells screened within the Hagarstown PMP (APW05S and APW12) ranged from 6.1×10^{-4} to 1.5×10^{-2} cm/s, with a geometric mean hydraulic conductivity of 3.1×10^{-3} cm/s (Ramboll, 2021).
- **Upper Confining Unit (UCU)**: The UCU consists of a thick, 26 feet thick on average with a maximum observed thickness of 59 feet at APW07, package of the low permeability clay and silt of the Vandalia Till Member. This unit is a laterally continuous layer between the base of

the upper drift and the top of the UA. The hydraulic conductivity of this unit was observed to range from 6.3 x 10^{-9} to 2.1 x 10^{-8} cm/s with a geometric mean of 1.1 x 10^{-8} cm/s (Rapps, 1997).

- **Uppermost Aquifer (UA):** The UA is composed of the Mulberry Grove Member, which has been classified as poorly graded sand, silty sand, clayey sand, and gravel. The top of the UA is highest in elevation in the north and east portions of the unit and slopes downward toward APW15. The top of unit elevations range from approximately 482 feet[1] (APW05 and APW10) to 425 feet (APW15). The average thickness of the Mulberry Grove sands and gravels is approximately 10 feet, with a maximum thickness of 30 feet observed at APW17. Field hydraulic conductivity tests conducted in 2021 at monitoring wells screened in the UA ranged from 2.0 x 10^{-4} to 1.5 x 10^{-1} cm/s with a geometric mean hydraulic conductivity of 6.8 x 10^{-3} cm/s. The highest conductivities are measured in APW15, APW16, and APW17 (Ramboll, 2021).
- **Lower Confining Unit (LCU):** The LCU is comprised of low permeability silt and clay of the Smithboro Till Member and the Banner Formation. The unit was encountered at thicknesses up to 36 feet in APW14), while the average thickness is 32 feet (Ramboll, 2021). The hydraulic conductivity of this unit was observed to be 1.4 x 10^{-7} cm/s (Rapps, 1997).
- **Bedrock Unit:** Shale bedrock of the Pennsylvanian-age Mattoon Formation (Willman et al., 1967) was encountered at the NPP during recent and historical investigations. Based on boring logs, the bedrock surface elevation at the NPP ranges from 408 feet (B141) to 445 feet (APW13) (Ramboll, 2021). Bedrock was not encountered at APW15, which was advanced to approximately 412 feet (Ramboll, 2021). This indicates that APW15, which is screened within the UA from 424 to 419 feet, is located in close proximity to the bedrock surface.

Groundwater flow in the UA is generally from north to south. However, UA wells also display flow converging towards a former surface drainage feature located west of the PAP and an area where the UA is lowest in elevation. Groundwater elevations in the UA vary seasonally, generally less than one foot per year, while across the PAP they range from approximately 490 to 530 feet, although flow directions are generally consistent. Groundwater elevations and contours for the April 24, 2023 monitoring event (Event 1 [E001]) are presented in **Figure 2-3**.

2.2 Groundwater Quality

Groundwater monitoring in accordance with the proposed GMP and sampling methodologies provided in the operating permit application for the PAP began in the second quarter of 2023. The 35 I.A.C § 845 groundwater monitoring system is displayed on **Figure 2-4** and consists of two background monitoring wells screened in the UA, 11 compliance wells screened in the UA, five compliance wells screened in the UD, and two temporary water level only surface water staff gages. The groundwater samples collected from the 18 wells are used to monitor and evaluate groundwater quality and demonstrate compliance with the groundwater quality standards listed in 35 I.A.C. § 845.600(a). The proposed monitoring wells yield groundwater samples that represent the quality of downgradient groundwater at the CCR boundary (as required in 35 I.A.C. § 845.630(a)(2)).

The E001 sampling event was completed on April 28, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), statistically derived values were compared with the GWPSs summarized in

[1] All elevations in this report are referenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

35 I.A.C. § 845.600 to determine exceedances of the GWPS (Ramboll, 2023a). The statistical determinations initiated during E001 identified the following GWPS exceedances at compliance groundwater monitoring wells:

- Lithium in UD/PMP well APW02;
- Sulfate in UD/PMP wells APW02, APW04, APW05S, and in UA well APW10;
- TDS in UD/PMP wells APW02, APW04, APW05S and APW12;
- Chloride in UA well APW15.

Pursuant to 35 I.A.C. § 845.650(e), an alternative source demonstration (ASD) was prepared and submitted to IEPA that presented evidence demonstrating that sources other than the PAP were the cause of the chloride GWPS exceedance listed above (Ramboll, 2023b).

The IEPA did not concur with the ASD due to the following alleged data gaps:

1. Source characterization of the CCR at the PAP must include total solids sampling in accordance with SW846.
2. Hydraulic conductivities from laboratory or in-situ testing must be collected, analyzed, and presented with hydrogeologic characterization of bedrock unit.
3. Characterization to include sample and analysis in accordance with 35 IAC § 845.640 of alternative source must be provided with the ASD.

IPGC submitted written comments and additional information in response to IEPA's request for information and filed a petition asking the Illinois Pollution Control Board (IPCB) to review IEPA's ASD denial. Implementing corrective actions to address naturally occurring compounds in groundwater will not be effective and IPGC believes that it is likely that it will succeed on the merits of the petition for review of the ASD denial. The petition included a motion for a partial stay of the 35 I.A.C. § 845 requirements as they apply to the exceedance of the chloride GWPS at the PAP. The IEPA had no objection to the requested stay, which was granted by IPCB on January 18, 2024. Therefore, the CMA will address identified GWPS exceedances, exclusive of chloride exceedances at APW15, in accordance with 35 I.A.C. § 845.660 and the partial stay. The 35 I.A.C. § 845.650 groundwater monitoring requirements will continue to ensure that there will be timely detection of any additional changes in groundwater quality during the stay. The inclusion of the chloride GWPS exceedance in the CAP process will remain under review pending IPCB's final action on IPGC's appeal of the IEPA ASD denial or until IPCB orders otherwise.

3. CORRECTIVE MEASURES ASSESSMENT METHODOLOGY

This section describes the CMA methodology initiated in response to the identification of exceedances of the GWPSs for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary of the PAP during the E001 groundwater monitoring event (Ramboll, 2023a). The CMA was initiated on November 5, 2023, within 90 days after the detection of exceedance(s) of GWPS. Under 35 I.A.C. § 845, owners and operators of existing CCR SI must initiate the assessment of corrective measures in accordance with 35 I.A.C. § 845.660 if one or more constituents are detected, and confirmed by an immediate resample, to be in exceedance of a GWPS in 35 I.A.C. § 845.600, and the owner or operator has not demonstrated that: a source other than the CCR SI caused the exceedance, or; that the exceedance of the GWPS resulted from error in sampling, analysis, statistical evaluation, natural variation in groundwater quality or a change in the potentiometric surface and groundwater flow direction (an ASD).

The CMA is the first step in developing a long-term CAP to address the GWPS exceedances at CCR SIs. The process provides a systematic, rational method for evaluating potential corrective measures by first identifying potentially viable technologies and assessing them using qualitative information to eliminate from consideration infeasible or otherwise unacceptable remedial technologies (*i.e.,* the 35 I.A.C. § 845.660 CMA). The remaining technologies will be evaluated individually, or assembled into combined alternatives, and further evaluated under the 35 I.A.C. § 845.670 CAP process.

This CMA identified applicable corrective measure technologies and evaluated them for viability, given the site-specific conditions and considerations at the PAP, by addressing the following 35 I.A.C § 845.660 evaluation criteria:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the corrective action plan; and
- Institutional requirements, such as State or local permit requirements or other environmental or public health requirements, that may substantially affect implementation of the corrective action plan.

The evaluation included qualitative and/or semi-quantitative screening of the potential corrective measures (technologies) relative to their general performance, reliability, and ease of implementation characteristics and their potential impacts, timeframes, and institutional requirements to assess the viability of each technology to address the GWPS exceedances at the PAP. This approach provided a reasoned set of corrective measures that could be used, either individually or in combination, to supplement the primary source control measures described in **Section 1.1**. This set of corrective measures will be further evaluated in the Corrective Action Alternatives Analysis (CAAA).

4. DESCRIPTION OF POTENTIAL CORRECTIVE MEASURE TECHNOLOGIES

The potential groundwater corrective measures summarized below are applicable to the PAP and were included in the CMA development and analysis. Site-specific considerations provided in **Section 2** were used to evaluate potential groundwater corrective measures. Each of the corrective measures evaluated may be capable of satisfying the requirements and objectives, listed in **Section 3**, to varying degrees of effectiveness. The corrective measure review process was intended to yield a set of applicable corrective measures that could be used to supplement the primary corrective action, which will be the source control activities described in **Section 1.1** (hybrid consolidate-and-cap approach with a geomembrane final cover system). The source control is expected to reduce downgradient concentrations in the UA to less than the GWPS via naturally occurring physical and chemical processes over an approximately 20-year timeframe. Ongoing monitoring will be an integral part of all corrective measures to verify and document the remedial process. The corrective measures ultimately advanced to the CAAA and selected in the CAP will be used to enhance the effectiveness of the source control and may be used independently or combined into specific remedial alternatives to leverage the advantages of multiple corrective measures to attain GWPSs.

Source control measures will be initiated for the PAP, as described in **Section 1.1**; all of the evaluated additional corrective measure technologies are proposed to be supplemental and complementary to source control activities. The following potential corrective measures, commonly used to mitigate groundwater impacts, were considered as a part of the CMA process:

- Source Control with Groundwater Polishing;
- Source Control with Groundwater Extraction (groundwater pumping wells or collection trenches);
- Source Control with a Cutoff Wall; and
- Source Control with In-Situ Treatment (Permeable Reactive Barrier [PRB] or In-Situ Chemical Treatment).

4.1 Source Control with Groundwater Polishing

Both federal and state regulators have long recognized that natural geochemical processes can be an acceptable component of a remedial action when it can achieve remedial action objectives in a reasonable timeframe. In 1999, the USEPA published a final policy directive (USEPA, 1999) for groundwater remediation and described the process as follows:

- *"The reliance on natural attenuation processes (within the context of a carefully controlled and monitored site cleanup approach) to achieve site-specific remediation objectives within a time frame that is reasonable compared to that offered by other more active methods. The natural attenuation processes that are at work in such a remediation approach include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in-situ processes include biodegradation; dispersion; dilution; sorption; volatilization; radioactive decay; and chemical or biological stabilization, transformation, or destruction of contaminants."*

The USEPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (USEPA, 1999). Natural geochemical processes may be appropriate as a "finishing step" after effective source control implementation (*i.e.*, groundwater polishing), to reduce the residual mass remaining in the groundwater after closure, if there are no risks to receptors and/or the contaminant plume is not expanding. Thus, groundwater polishing would be used in conjunction with the significant planned source control effort at the site, which will consist of a hybrid consolidate-and-cap approach with a final cover system described in **Section 1.1**.

In 2015, USEPA addressed remediation of inorganic compounds in groundwater and noted that the use of natural geochemical processes to address inorganic contaminants: (1) is not intended to constitute a treatment process for inorganic contaminants; (2) when appropriately implemented, can help to restore an aquifer to beneficial uses by immobilizing contaminants onto aquifer solids and providing the primary means for attenuation of contaminants in groundwater; and (3) is not intended to be a "do nothing" response (USEPA, 2015b). Rather, documenting the applicability of natural geochemical processes for groundwater remediation should be thoroughly and adequately supported with site-specific characterization data and analysis (USEPA, 1999; USEPA, 2007; USEPA, 2015b):

Both physical and chemical processes can contribute to the reduction of the small amount of residual mass remaining after closure of the PAP, and the toxicity, mobility, volume, or concentration of contaminants in groundwater. Physical processes applicable to CCR constituents in groundwater include dilution, dispersion, and flushing. Chemical processes applicable to CCR constituents in groundwater include precipitation and coprecipitation (*e.g.,* incorporation into sulfide minerals), sorption (*e.g.,* to iron, manganese, aluminum; to other metal oxides or oxyhydroxides; or to sulfide minerals or organic matter), and ion exchange.

All inorganic compounds are subject to physical processes and under typical environmental conditions, the physical mechanisms most often exert the dominant control on the CCR constituents of interest. Chemical mechanisms are also likely to be active, though not often dominant, such as adsorption, ion exchange, and organic complexation. In combination with source control, these natural controls can provide an effective means to polish residual loading and achieve the GWPS in a reasonable timeframe. Additional data collection and analysis may be required to support the USEPA's evaluation framework (USEPA, 2015b) and obtain regulatory approval.

4.2 Source Control with Groundwater Extraction

Groundwater extraction is one of the most widely used groundwater corrective technologies and has a long history of performance. This corrective measure includes installation of one or more groundwater pumping wells or an extraction trench to control and extract impacted groundwater. Groundwater extraction captures and contains impacted groundwater and can limit plume expansion and/or off-site migration. Construction of a groundwater extraction system typically includes, but is not limited to, the following primary components:

- Designing and constructing a groundwater extraction system consisting of one or more extraction wells or trenches and operating at a rate to allow capture of CCR impacted groundwater within the UA and or the UD/PMP.

- Management of extracted groundwater, which may include modification to the existing NPDES permit.
- Ongoing inspection and maintenance of the groundwater extraction system.

Remediation of inorganics by groundwater extraction can be effective, but systems do not always perform as expected. A combination of factors, including geologic heterogeneities, difficulty in flushing low-permeability zones, and rates of contaminant desorption from aquifer solids can limit effectiveness. Groundwater extraction systems require ongoing operation and maintenance to address issues such as iron bacteria and well fouling and to ensure optimal performance. The extracted groundwater must be managed, either by ex-situ treatment or disposal.

Groundwater extraction may reduce the timeframe to achieve GWPS and limit the off-site migration of constituents that exceed the GWPS. Extraction could be accomplished using a groundwater pumping well system or an extraction trench.

4.3 Source Control with Groundwater Cutoff Wall

Since the late 1970s and early 1980s, vertical cutoff walls have been used to control and/or isolate impacted groundwater. Low-permeability cutoff walls can be used to prevent horizontal off-site migration of potentially impacted groundwater. Cutoff walls act as barriers to lateral transport of impacted groundwater and can isolate soils that have been impacted by CCR to prevent mixing with unimpacted groundwater. Cutoff walls are often used in conjunction with an interior pumping system to establish an inward gradient within the cutoff wall. The gradient imparted by the pumping system maintains an inward flow through the wall, keeping it from acting as a groundwater dam and controlling potential end-around or breakout flow of contaminated groundwater. Constructing the cutoff wall such that it intersects a low-permeability material at its base, referred to as "keying", greatly increases its effectiveness.

A commonly used cutoff wall construction technology is the slurry trench method, which consists of excavating a trench and backfilling it with a soil-bentonite mixture, often created with the excavated soils, or, for deeper walls, a cement-bentonite mixture that is produced at an onsite batch plant. The trench is temporarily supported with bentonite slurry pumped into the trench during excavation (D'Appolonia & Ryan, 1979). Cutoff wall excavation uses conventional hydraulic excavators, hydraulic excavators equipped with specialized booms to extend their reach (*i.e.,* long-stick excavators), clamshells, or more specialized equipment such as hydromills, secant-pile drill rigs, or one-pass machines, depending upon trench depth, material excavated, and type of material that the wall is keyed into.

Cutoff walls are a widely accepted technology for containing impacted groundwater. Combining groundwater polishing with a limited cutoff wall and groundwater extraction in specific areas may provide advantages over independent use of these potential corrective technologies. Cutoff walls can be used in combination with groundwater extraction or as part of a PRB system (as the "funnel" in a funnel-and-gate system; **Section 4.4**).

4.4 Source Control with In-Situ Chemical Treatment

The use of in-situ treatment, either by injection or PRBs is a widely used technology for treating impacted groundwater. However, in-situ treatment techniques for lithium and sulfate are not well established, therefore performance is unknown.

Chemical treatment could consist of injection of reactive materials into the subsurface to treat contaminants at specific, targeted locations. Alternatively, treatment could be accomplished via PRB, where subsurface barriers (*i.e.,* cutoff walls) are placed at locations designed to direct the contaminant plume along a flow path through the reactive media. In either system, the contaminants are transformed or otherwise rendered into environmentally acceptable forms to attain remediation concentration goals downgradient of the barrier (Electric Power Research Institute [EPRI], 2006).

As groundwater passes through the PRB under natural gradients, dissolved constituents in the groundwater react with the reactive media and are transformed or immobilized. A variety of media have been used or proposed for use in PRBs. Zero-valent iron (ZVI) has been shown to effectively immobilize some CCR constituents, including arsenic, chromium, cobalt, molybdenum, selenium, and sulfate. Use of a combination media consisting of ZVI and a boron-selective ion exchange resin to treat boron has been documented in a pilot-scale test (EPRI, 2006).

System configurations include continuous PRBs, in which the reactive media extends across the entire path of the contaminant plume; and funnel-and-gate systems, where low-permeability barriers are installed to control groundwater flow through a permeable gate containing the reactive media. Continuous PRBs intersect the entire contaminant plume and do not materially impact the groundwater flow system. Design may or may not include keying the PRB into a low-permeability unit at depth. Funnel-and-gate systems utilize a system of barriers to groundwater flow (funnels) to direct the contaminant plume through the reactive gate. The barriers, typically some form of cutoff wall, are keyed into a low-permeability unit at depth to prevent short circuiting of the plume. Funnel-and-gate design must consider the residence time to allow chemical reactions to occur. Directing the contaminant plume through the reactive gate can significantly increase the flow velocity, thus reducing residence time.

Design of in-situ treatment systems requires rigorous site investigation to characterize the site hydrogeology and to delineate the contaminant plume. A thorough understanding of the geochemical and redox characteristics of the plume is critical to assess the feasibility of the process and select appropriate reactive media. Laboratory studies, including batch studies and column studies using samples of site groundwater, are needed to determine the effectiveness of the selected reactive media at the site (EPRI, 2006). The main considerations in selecting reactive media are as follows (Gavaskar et al., 1998; cited by EPRI, 2006):

- Reactivity - The media should be of adequate reactivity to immobilize a contaminant within the residence time of the design.
- Hydraulic performance - The media should provide adequate flow through the PRB, meaning a greater particle size than the surrounding aquifer materials. Alternatively, gravel beds have been emplaced in front of barriers to direct flow through the barrier.
- Stability - The media should remain reactive for an amount of time that makes its use economically advantageous over other technologies.
- Environmentally compatible by-products - Any by-products of media reaction should be environmentally acceptable. For example, iron released by zero-valent iron corrosion should not occur at levels exceeding regulatory acceptance levels.
- Availability and price: The media should be easy to obtain in large quantities at a price that does not negate the economic feasibility of using a PRB.

5. ASSESSMENT OF CORRECTIVE MEASURE TECHNOLOGIES

This CMA was initiated to address exceedances of the 35 I.A.C. § 845.600 GWPS for lithium, sulfate, and TDS at the downgradient waste boundary of the PAP identified during the E001 groundwater monitoring event (**Section 2.2**).

5.1 Requirements

The potential groundwater corrective technologies described in the previous section were evaluated relative to the requirements presented in **Section 3** and reiterated below:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the corrective action plan; and
- Institutional requirements, such as State or local permit requirement or other environmental or public health requirements that may substantially affect implementation of the corrective action plan.

Table 5-1 presents the qualitative CMA evaluation for each corrective technology relative to these requirements, as well as their ability to address lithium, sulfate, and TDS GWPS exceedances. The following sections provide a summary of these evaluations and a discussion of the potential groundwater corrective measure technologies that may be viable, either independently or in combination, to address GWPS exceedances. This section also provides a summary of corrective measure technologies that have been retained and advanced for evaluation as part of the CAAA process for selecting the final remedy for the PAP per 35 I.A.C. § 845.670.

5.2 Groundwater Corrective Technology Assessment

Source control, consisting of CCR consolidation and closure-in-place (CIP) with a final cover system, will be the primary groundwater corrective measure for the PAP. Closure is expected to be completed in 2028 and each of the potential groundwater corrective measure technologies would supplement the positive impact of the closure activities. The following sections evaluate groundwater corrective measure technologies that, when combined with site closure, may be viable to address the lithium, sulfate, and TDS GWPS exceedances. Technologies that are not viable for addressing exceedances of GWPS at the PAP will be eliminated from further evaluation and viable technologies will be advanced for further evaluation as part of the CAAA process per 35 I.A.C. § 845.600.

5.2.1 Source Control with Groundwater Polishing

Source control corrective measures (**Section 1.1**) will reduce the mass loading to the groundwater system and the groundwater polishing process could decrease the timeframe for attainment of GWPS in the UA. Groundwater flow and fate and transport modeling incorporating only physical processes indicate that source control would meet GWPS in approximately 20 years. Physical processes are expected to perform well in the UA, as discussed below.

Groundwater polishing by natural geochemical processes is a widely accepted component of groundwater remediation and is routinely approved by the IEPA when paired with source control. The performance of groundwater polishing as a groundwater corrective measure varies based on site-specific conditions and additional data collection may be needed to support the design and achieve regulatory approval. The sandy nature of the UA suggests good performance by physical processes in addressing the sulfate in the UA. The chemical processes in the fine-grained UD require further evaluation.

Naturally occurring geochemical processes are ongoing at the PAP and will continue to affect groundwater constituent concentrations during and after PAP closure. Ongoing monitoring of groundwater conditions is needed to better understand the mechanisms and efficacy of the groundwater polishing process and to confirm the effectiveness over time. Thus, additional groundwater sample collection and analyses would be required to characterize potential mechanisms, as discussed above, and to provide long term monitoring of the remedial progress. Enhancements to the groundwater monitoring system may be required to ensure that groundwater polishing is occurring as predicted by the groundwater and consistent with the adaptive site management approach. The reliability of groundwater polishing as a groundwater corrective measure is high because operation and maintenance requirements are limited. However, the reliability can also vary based on site-specific hydrogeologic and geochemical conditions.

Following characterization and approval of the CAP, monitoring of the groundwater polishing processes and comparison to functional goals established to monitor progress toward the remedial objective could begin prior to, or concurrently with, site closure activities. Installing additional monitoring wells could begin as quickly as within a few months of CAP approval. The time required could be reduced if existing groundwater monitoring well systems could be utilized for monitoring.

No potential safety impacts or exposure to human health or environmental receptors are expected to result from the groundwater polishing processes. Timeframes to achieve GWPS are dependent on site-specific conditions, which require detailed technical analysis which are ongoing and will be evaluated in connection with the CAAA. Selecting groundwater polishing as a corrective measure for the PAP will require approval of the closure and CAP permits by the IEPA.

Monitoring the groundwater polishing to track progress toward achievement of the GWPS, in conjunction with source control at the PAP, would require long-term maintenance and monitoring of the groundwater monitoring system to confirm source control and verify the effectiveness in reducing groundwater concentrations to levels below the GWPS. System design could begin immediately after approval of the CAP permit. Additional investigations to characterize site conditions and installation of the final monitoring system could be performed concurrently with the source control (unit closure) activities, which are currently expected to be completed in 2028.

Groundwater polishing processes will continue before and after source control implementation and may be a viable corrective measure for the sulfate and lithium exceedances at the PAP. Therefore, these processes are being advanced to the CAAA for further evaluation.

5.2.2 Source Control with Groundwater Extraction

Source control will reduce the mass loading to the groundwater system and implementing a groundwater extraction system may reduce the time required to attain the GWPS in the UA.

However, the groundwater impacts already present in the low permeability PMP may limit the reduction in time to attain the GWPS that can be achieved by a groundwater extraction system.

Groundwater extraction is a widely accepted corrective measure with a long track record of performance and reliability. It is routinely approved by the IEPA. For a corrective measure using groundwater extraction to effectively control off-site flow and/or to remove potentially contaminated groundwater, horizontal and vertical capture zone(s) must be created. However, the low permeability PMP would restrict the ability to pump at rates high enough to establish the required capture zone(s) or would require a high density of wells or a trench drainage system. The performance of a groundwater extraction system would be expected to be effective in the high permeability UA (mean hydraulic conductivity of 6.8×10^{-3} cm/s). However, the proximity and influence of Newton Lake to the impacted area of the UA would potentially result in large volumes of extracted groundwater and lake water. Cutoff walls (**Section 4.3**) could also be used in conjunction with a pumping system to control potential groundwater movement from the lake. A groundwater extraction system in the PMP would be limited by its low permeability (mean hydraulic conductivity of 1.3×10^{-5} cm/s); however, a low volume extraction trench in the PMP could be used to enhance groundwater capture from the PMP.

Implementation of a groundwater extraction system presents design challenges due to the proximity to Newton Lake. An extraction system in the UA would have to consider the potential for extracting unimpacted lake water. Construction of an extraction system between the PAP and Newton Lake may be challenging due to the physical site constraints (limited construction area). Extracted groundwater (and potentially lake water) would need to be managed, which may include modification to the existing NPDES permit and treatment prior to discharge, if necessary. Specialized treatment equipment may be required, and ongoing operations and maintenance activities would be necessary.

There could be some impacts associated with constructing and operating a groundwater extraction system, including some limited exposure to extracted groundwater. Additional data collection and analyses would be required to design an extraction system. Construction could be completed within 1 year following completion of a final design. Time of implementation is approximately 3 to 4 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on site-specific conditions. An extraction system may reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling. However, accelerated attainment of the GWPS is expected to be limited by the low permeability of the PMP.

Implementing a groundwater extraction system at the PAP would require IEPA approval of the CAP permit, and discharge of extracted groundwater may require a modification to the NPDES permit, as well as possibly permitting and construction of a new outfall. Depending upon the location of the extraction system an Illinois Department of Natural Resources (IDNR) dam safety modification permit may also be required to construct an extraction system.

Groundwater extraction could be viable corrective measure for the sulfate and lithium exceedances at the PAP. Implementation of groundwater extraction may require combining an extraction system with a cutoff wall to prevent potential inflow of water from Newton Lake. Therefore, groundwater extraction is being advanced to the CAAA for further evaluation.

5.2.3 Source Control with Groundwater Cutoff Wall

Source control will reduce the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. A low permeability cutoff wall could be used in combination with a groundwater extraction system in the UA to reduce the potentially high volumes of extracted groundwater that would be captured by and extraction system between the PAP and Newton Lake. A cutoff wall could reduce the water management and treatment requirements for an extraction system.

Groundwater cutoff walls are a widely accepted corrective measure used to control and/or isolate impacted groundwater and are routinely approved by the IEPA. Cutoff walls have a long history of reliable performance as hydraulic barriers, provided they are properly designed and constructed. However, if not coupled with a groundwater extraction system, a cutoff wall will provide directional groundwater control only and may result in redistribution of contaminants and potentially GWPS exceedances at new locations.

Cutoff walls are designed to act as hydraulic barriers; as a result, cutoff walls inherently alter the existing groundwater flow system. Changes to the existing groundwater flow system may need to be controlled to maximize the effectiveness of the remedy by, for example, combining a cutoff wall with groundwater extraction to control build-up of hydraulic head upgradient and around the cutoff walls. The effectiveness of a cutoff wall as a hydraulic barrier also relies on the contrast between the hydraulic conductivity of the native geologic materials and the cutoff wall. The most effective barriers have hydraulic conductivity values that are several orders of magnitude lower than the geologic materials they are in contact with. A cutoff wall designed with hydraulic conductivity of 1×10^{-7} cm/sec would be two orders of magnitude lower than the UD with a mean conductivity of 1.3×10^{-5} cm/sec, limiting its performance. Performance and reliability of a cutoff wall in the UD/PMP would also be limited due to the difficulty in delineating the intermittent sandy zones within the unit. Construction of a cutoff wall extending into the UA would be four orders of magnitude lower than the UA, with a mean hydraulic conductivity of 6.8×10^{-3} cm/s and would be an effective containment method in the UA and could improve the performance of a UA extraction system.

Constructing a cutoff wall may be challenging due to the physical site constraints (limited construction area due to the proximity to Newton Lake), particularly if used in combination with an extraction system. In that case, both the extraction system and the cutoff wall would need to be located between the PAP and Newton Lake, which would increase the construction complexity and could result in structural impacts to the embankment dikes, depending on the location of the wall. Specialized construction contractor(s) may be required, which could delay implementation.

Additional data collection and analyses would be required to design a cutoff wall. Construction of only the cutoff wall could be completed within 2 to 3 years. Time of implementation is approximately 5 to 8 years, including characterization, design, permitting and construction. Construction could possibly be accelerated by combining with site closure activities. To attain GWPS, cutoff walls require a separate groundwater corrective measure to operate in concert with the cutoff wall(s). Cutoff walls are commonly coupled with groundwater polishing and/or groundwater extraction as groundwater corrective measures. The time to attain GWPS is dependent on the selected groundwater corrective measure or measures that are coupled with the cutoff walls.

Constructing a cutoff wall at the PAP would require IEPA approval of the CAP permit and, depending on the location, an IDNR dam safety modification permit may be required.

A cutoff wall at the PAP alone would not be a viable corrective measure for the sulfate, lithium, and TDS exceedances at the PAP. However, a cutoff wall may serve to increase the efficiency of a groundwater extraction system by preventing inflow of water from Newton Lake. Therefore, the cutoff wall is being advanced to the CAAA for further evaluation.

5.2.4 Source Control with In-Situ Chemical Treatment

Source control will reduce the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. Use of in-situ treatment, either through targeted injection of reactive media or in PRB systems, to transform contaminants into environmentally acceptable forms to attain the GWPS was considered.

In-situ treatment using ion exchange to address sulfate and lithium exceedances in groundwater is not an established or widely accepted groundwater corrective measure; therefore, its performance and reliability are unknown. Regulatory acceptance of this innovative approach to achieving the GWPS is uncertain.

In-situ treatment presents design and construction challenges, including targeted reactive media delivery via injection to the sandier zones in the UD/PMP and the complicated construction that would be required for a PRB system in close proximity to Newton Lake (if possible). Depending upon the location of the PRB system, construction may affect the PAP embankment and/or final cover system and periodic change-outs of ion exchange (IX) resin media may be required.

Additional data collection and analyses would be required to design an in-situ treatment system and bench scale and/or pilot scale testing may be required to demonstrate performance and reliability. Time of implementation is approximately 4 to 6 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on demonstrations of performance and reliability along with regulatory acceptance. It is not known whether in-situ treatment would reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling.

Due to the uncertain performance, reliability and potential for not obtaining regulatory acceptance, in-situ chemical treatment is not a viable corrective measure for the sulfate and lithium exceedances at the PAP and is not being advanced to the CAAA for further evaluation.

5.3 Technologies Advanced to CAAA

Based on the evaluations presented above, the following potential corrective technologies are being advanced to the CAAA, individually or in combination, for more detailed evaluations:

- Source control with groundwater polishing;
- Source control and with groundwater extraction; and
- Source control with a groundwater cutoff wall.

Potential Corrective Measure Technology	Evaluation Factors						
	Performance	**Reliability**	**Ease of Implementation**	**Potential Impacts of Remedy** (safety impacts, cross-media impacts, control of exposure to any residual contamination)	**Time Required to Begin and Implement Remedy[1]**	**Time to Attain Groundwater Protection Standards**	**Institutional Requirements** (state/local permit requirements, environmental/public health requirements that affect implementation of remedy)
Source Control with Aquifer Polishing	Performs best paired with source control, which is expected to be completed at the site in 2028. Site conditions are favorable for physical processes of sulfate and lithium. Good performance is expected for physical processes due to the sandy nature of the Uppermost Aquifer. Geochemical process performance may be limited.	Ongoing analysis will evaluate whether the geochemical mechanism has low reversibility, the Uppermost Aquifer and/or the Upper Drift have sufficient capacity, and the hydrogeology is favorable for physical processes. Possibly low reliability for lithium due to reversibility.	Evaluation is underway and is expected to be completed in 2024. Long-term monitoring would be required. Implementing would not require extensive specialized equipment or contractors.	None identified.	Approximately 90 days after CAP permit approval.	Dependent on site specific conditions. Accelerated attainment of GWPS will be limited by the low permeability of the Upper Drift and may not significantly improve attainment of the GWPS in the Uppermost Aquifer to less than the 20 years post-closure predicted by the groundwater model.	IEPA approval of the closure and CAP permits is required.
Source Control with Groundwater Extraction	A widely accepted, routinely approved technology. Performance expected to be effective in the relatively high permeability, sandy, Uppermost Aquifer but would be limited in the low permeability silts and clays of the Upper Drift.	Reliable if properly designed, constructed, and maintained. Reliability is expected to be high in the Uppermost Aquifer but may be affected by the potential need for dense well spacing to ensure overlapping cones of depression and complete groundwater capture in the low permeability silts and clays of the Upper Drift. Groundwater treatment prior to discharge can be considered if indicated by performance monitoring.	Groundwater flow direction in Uppermost Aquifer and physical site constraints (proximity and influence of Newton Lake) may make locating capture wells challenging and would result in a high volume of extracted water. In the Upper Drift, there would likely be a limited zone of influence for capture wells, which would likely require dense well spacing or installation of an extraction trench. Site constraints could make well installation challenging. Specialized contractors are not expected to be needed. Extracted groundwater would require management, possibly including treatment. Groundwater treatment, if needed, may required specialized equipment/contractors.	Alters groundwater flow system and there is some potential for some limited exposure to extracted groundwater.	Design, permitting and construction is expected to take 3 to 4 years after CAP permit approval.	Dependent on site specific conditions. Accelerated attainment of GWPS will be limited by the low permeability of the Upper Drift and may not significantly improve attainment of the GWPS to less than the 20 years post-closure predicted by the groundwater model for source control and aquifer polishing.	IEPA approval of the closure and CAP permits is required. Extracted groundwater discharge may require an NPDES permit modification or permitting and constructing a new outfall, depending on the groundwater flow rates. A IDNR dam safety modification permit might also be required, depending on location of wells and settlement potential.
Source Control with Groundwater Cutoff Wall	Widely accepted and routinely approved technology with good performance if properly designed and constructed, however containment using cutoff walls in the low permeability Upper Drift materials would likely not be effective. If not combined with extraction wells, a cutoff wall will provide directional control only, thus redirecting flow to other areas where GWPS may be exceeded.	Reliable for groundwater directional control in the Uppermost Aquifer if properly designed and constructed. Reliability in the discontinuous sandy deposits of the Upper Drift would be limited by the ability to delineate the sandy deposits.	Widely used, established technology. Groundwater flow direction in Uppermost Aquifer and physical site constraints (proximity and influence of Newton Lake) make locating a cutoff wall challenging. Potential need to locate cutoff wall either upon the existing embankment or upon the (post-closure) final cover would increase the construction complexity. May require specialized construction equipment and delay implementation.	Alters groundwater flow system but does not provide any treatment. Can result in unintended consequences resulting from redirecting contaminants to areas where they are not currently present. May cause structural impacts to the embankment dikes, depending on the location of the wall.	Design, permitting and construction is expected to take 5 to 8 years after CAP permit approval. Implementation could be accelerated by combining with closure construction activities.	Provides groundwater directional control only. Combination with another groundwater corrective measure, such as groundwater extraction or a permeable reactive barrier, may not significantly improve attainment of the GWPS to less than the 20 years post-closure predicted by the groundwater model for source control and aquifer polishing.	IEPA approval of the closure and CAP permits is required. An IDNR dam safety permit may also be required depending on the location of the cutoff wall.
Source Control with In-Situ Chemical Treatment	In-Situ treatment using ion exchange (IX) is not well established for sulfate and lithium, therefore performance is unknown.	Unknown reliability for sulfate and lithium.	Design challenges for a funnel and gate PRB system due to depth, stratigraphy and proximity to the Newton Lake. Challenge to target reactive media delivery in the low permeability Upper Drift for in-situ treatment (injection). Could require periodic change-outs of IX resin media.	Depending on the location of a PRB, it's construction may affect the embankment/final cover system (structural impacts to the dike, inducting settlement, impacts to final cover system, etc.).	May require bench scale and/or pilot scale testing as part of design. Design, permitting and construction is expected to take 4 to 6 years after CAP permit approval.	There is uncertainty regarding whether a permeable reactive barrier would reduce sulfate concentrations to achieve the GWPS. Dependent on conditions specific to the reactive media used and the site. Treatment technology not well understood.	IEPA approval of the CAP permit is required. IEPA approval of this innovative and relatively unproven solution may be challenging. An IDNR dam safety permit may also be required depending on the location of the PRB.

Notes: [1] Time required to begin and implement remedy includes design, permitting and construction.

GWPS - Groundwater Protection Standard

ACRONYMS AND ABBREVIATIONS

35 I.A.C.	Title 35 of the Illinois Administrative Code
40 C.F.R.	Title 40 of the Code of Federal Regulations
ASD	Alternative Source Demonstration
bgs	below ground surface
BOD	biological oxygen demand
CCR	coal combustion residuals
CEC	Cation Exchange Capacity
cm/s	centimeters per second
COC	chain-of-custody
COD	chemical oxygen demand
CORRACTS	RCRA Corrective Action Sites
CSM	conceptual site model
CWA	Clean Water Act
DO	dissolved oxygen
EDR	Environmental Data Resources, Inc.
E001	Event 1
GCSM	geochemical conceptual site model
GPS	Global Positioning System
GWPS	groundwater protection standard
IEPA	Illinois Environmental Protection Agency
IPCB	Illinois Pollution Control Board
kHz	kilohertz
LCL	lower confidence limit
LCU	lower confining unit
LF 1	Phase 1 Landfill
LF 2	Phase 2 Landfill
LOI	loss-on-ignition
LUST	Leaking Underground Storage Tanks
LVW	low-volume wastewater
MCL	Maximum Contaminant Level
mg/kg	milligrams per kilogram
mg/L	milligrams per liter
NAVD88	North American Vertical Datum 1988
NPDES	National Pollutant Discharge Elimination System
NPP	Newton Power Plant
NRT/OBG	Natural Resource Technology, an OBG Company
PAP	Primary Ash Pond
PMP	potential migration pathway
QA/QC	quality assurance/quality control
Ramboll	Ramboll Americas Engineering Solutions, Inc.
RCRA	Resource Conservation and Recovery Act
RISC	Risk Integrated System of Closure

RTK	real-time kinematic
SAP	Sampling and Analysis Plan
SI	surface impoundment
SMA	sediment management area
SOP	standard operating procedures
SPLP	synthetic precipitation leaching procedure
SVOC	semi-volatile organic compounds
TBD	To Be Determined
TDS	total dissolved solids
TOC	total organic solids
TSD	Treatment, Storage, and Disposal
TSS	total suspended solids
UA	uppermost aquifer
UCU	upper confining unit
UD	upper drift
USACE	United States Army Corps of Engineers
USGS	United States Geological Survey
VOC	volatile organic compounds
XRD	x-ray diffraction
XRF	x-ray fluorescence

EXECUTIVE SUMMARY

Groundwater samples collected at the Newton Power Plant (NPP) Primary Ash Pond (PAP) during April 2023 for the Quarter 2, 2023 compliance sampling event (Event 1 [E001]) were evaluated for exceedances of the groundwater protection standards (GWPS) described in Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845.600. Exceedances were identified in the following hydrostratigraphic units and wells:

- Detected uppermost aquifer (UA) Exceedances:
  - Chloride at APW15
  - Sulfate at APW10
- Detected Upper Drift (UD) (potential migration pathway [PMP]) Exceedances:
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - Total dissolved solids (TDS) at APW02, APW04, and APW05S

An alternative source demonstration (ASD) was completed for the chloride exceedance at UA monitoring well APW15. The Illinois Environmental Protection Agency (IEPA) did not concur with the ASD. The non-concurrence was appealed, and the Illinois Pollution Control Board (IPCB) granted a stay on January 18, 2024.

As required by 35 I.A.C. § 845.650(d)(1) this Report characterizes the nature and extent of sulfate, lithium, and TDS, and relevant site conditions to determine how they may affect the corrective measures ultimately selected for the PAP and documents the additional measures taken in accordance with 35 I.A.C. § 845.650(d).

Sulfate (and TDS) above the GWPS was encountered within the two hydrostratigraphic units: the shallow UD and associated PMP, and in the UA where it occurs at it's highest elevation. In both units, the extent of sulfate above the GWPS is defined laterally by existing wells and Newton Lake, and vertically by the presence of low permeability tills or deeper wells that do not have GWPS exceedances. The sulfate concentrations are attenuated physically through dilution and dispersion; and may be geochemically attenuated by sorption to iron oxides. The sulfate and TDS concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1].

Lithium above the GWPS was encountered only within the shallow UD at APW02. The extent of lithium above the GWPS is currently being further defined laterally with additional wells but is ultimately defined by Newton Lake. Vertically, the extent of lithium above the GWPS is limited by presence of low permeability tills and defined by deeper wells that do not have GWPS exceedances. The lithium concentrations are attenuated physically through dilution and dispersion and may be geochemically attenuated by sorption to and incorporation into clay minerals. The lithium concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1].

1. INTRODUCTION

35 I.A.C. § 845.650(d)(1) requires the owner or operator of a coal combustion residuals (CCR) surface impoundment (SI) to characterize the nature and extent of a release and relevant site conditions that may affect the remedy ultimately selected for a CCR SI if any constituent regulated under 35 I.A.C. § 845 is found to exceed the GWPS. This report documents the nature and extent of constituents detected above the GWPS that are attributable to the NPP PAP.

The groundwater data and analysis in this report includes results from historical sampling (initiated in 2015) through E001, which was completed on April 28, 2023. Results of the E001 event were submitted and placed in the facility's operating record by August 7, 2023 as required by 35 I.A.C. § 845.800(d)(15), within 60 days of receiving final laboratory analytical data [2]. The statistical determination presented in the report identified the following exceedances of the GWPS at compliance groundwater wells in the following hydrostratigraphic units:

- Detected UA Exceedances:
  - Chloride at APW15
  - Sulfate at APW10
- Detected UD/PMP Exceedances:
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - Total dissolved solids (TDS) at APW02, APW04, and APW05S

An Alternative Source Demonstration (ASD), as allowed by 35 I.A.C. § 845.650(e) was completed for the chloride exceedance at UA monitoring well APW15 [3]. The Illinois Environmental Protection Agency (IEPA) did not concur with the ASD in a letter dated November 7, 2023 due to the following data gaps:

1. Source characterization of the CCR at the PAP must include total solids sampling in accordance with SW846.
2. Hydraulic conductivities from laboratory or in-situ testing must be collected, analyzed and presented with the hydrogeologic characterization of bedrock unit.
3. Characterization to include sample and analysis in accordance with 35 I.A.C. § 845.640 of alternative source must be provided with the ASD.

On December 15, 2023, Illinois Power Generating Company (IPGC) submitted a Petition for Review [4] of the non-concurrence with the chloride ASD and Motion for Stay to the IPCB. The IPCB granted a stay on January 18, 2024. Therefore, the nature and extent of chloride is not discussed in this document. This Nature and Extent Report discusses in detail the extent of the sulfate, lithium, and TDS exceedances as well as a geochemical conceptual site model (GCSM) describing the nature of these exceedances.

2. UNIT BACKGROUND

2.1 Site Location and Description

The NPP is located in Jasper County in the southeastern part of central Illinois, approximately seven miles southwest of the town of Newton (**Figure 2-1**). The NPP operates as a coal-fired power plant with three CCR units present, including the PAP and two landfills: the Phase 1 Landfill (LF 1) located northwest and west of the PAP, and the Phase 2 Landfill (LF 2) located to the west of the PAP. The PAP is located within Section 26 and the west half of Section 25, Township 6 North, Range 8 East. The PAP is located south of the NPP and surrounded by Newton Lake to the south, east, and west (**Figure 2-2**). Beyond the lake is additional agricultural land.

2.2 Description of CCR Unit

The PAP is an unlined CCR SI used to manage CCR and non-CCR waste streams at the NPP. The PAP was constructed in 1977 and has a design capacity of approximately 9,715 acre-feet. There is also a non-CCR 83.6 acre-feet Secondary Pond located immediately south of the PAP. The PAP has a surface area of 404 acres and the Secondary Pond has an area of 9.3 acres. The PAP currently receives stormwater runoff, bottom ash, fly ash, and low-volume wastewater (LVW) from the plant's two coal-fired boilers. The SI is operated per National Pollutant Discharge Elimination System (NPDES) Permit No. IL0049191, Outfall 001 (located at the Secondary Pond).

Prior to PAP construction, an incised stream gully existed at the site of the PAP. Areas within the impoundment were excavated during construction for native materials used to build the containment berms in 1977.

Initial operation of the NPP, beginning with Unit 1 being put into service in 1977, included combustion of Illinois coal until 1997-1998, at which point the plant switched to low sulfur coal from the Powder River Basin. Both fly and bottom ash were sluiced wet to the PAP until 1979 when the wet scrubber (including sodium carbonate injection) came online. The fly ash was then mixed with the scrubber cake and placed in the Phase I landfill while bottom ash continued to be sluiced to the PAP. The scrubber was shut down in the Fall of 1996 and fly ash was sluiced wet to the PAP again. Fly ash and bottom ash have both been sluiced to the PAP since the plant began operation in 1977. Emission controls consisting of injection of halogenated activated carbon to reduce mercury emissions were implemented prior to 2009 under an agreement with IEPA. The Newton Landfill Phase 1 (closed) and Phase 2 (operational) receive the wastes generated from the emissions controls. Review of historic aerial imagery of the PAP (observations summarized in **Figure 2-3**) illustrate the extent of CCR deposition through time as well as potential CCR variability (based on observed differences in color). Characterization of the CCR material including total metals analysis of eight samples of materials within the PAP and completion of monitoring wells screened within the CCR was completed in areas of the PAP that were safely accessible in 2021 to meet the requirements of 35 I.A.C. § 845 (**Figure 2-4**) (Hydrogeologic Site Characterization Report [5]).

2.3 Geology and Hydrogeology

Significant site investigation has been completed at the NPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the PAP has been well characterized and detailed in the Hydrogeologic Site Characterization Report [5].

2.3.1 Hydrostratigraphic Units

Materials at the site have been categorized into six hydrostratigraphic units at the PAP based on stratigraphic relationships, geologic composition, and common hydrogeologic properties. The units, listed from surface downward, are summarized as follows:

- **CCR:** CCR consists of fly and bottom ash within the PAP and may be present from the surface (approximately 545 to 555 feet[1]) to a minimum elevation of approximately 485 feet NAVD88 (**Figure 2-5**). CCR material is lowest in elevation along a historic drainage feature that runs approximately through the center of the PAP. Groundwater elevations measured in piezometers screened within the PAP indicate that the phreatic surface ranges from approximately 535 to 547 feet, which is above groundwater measured outside the CCR unit in the surrounding monitoring wells.
- **Upper Drift (UD)/Potential Migration Pathway (PMP):** The UD is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.,* PMP).
  - **Hagarstown Member/PMP:** The Hagarstown Member consists of discontinuous sandier deposits of the UD, where present, and overlies the Vandalia Till.
- **Upper Confining Unit (UCU):** This unit consists of the low permeability clay and silt of the Vandalia Till Member (Vandalia Till).
- **Uppermost Aquifer (UA):** This unit is composed of the Mulberry Grove Formation, which has been classified onsite as poorly graded sand, silty sand, clayey sand, and gravel.
- **Lower Confining Unit (LCU):** This unit is comprised of low permeability silt and clay of the Smithboro Till Member (Smithboro Till) and the Banner Formation.
- **Bedrock Unit:** Shale bedrock of the Pennsylvanian-age Mattoon Formation [6] was encountered at the NPP during recent and historical investigations. Based on boring logs, the bedrock surface elevation at the NPP ranges from 408 feet (B141) to 445 feet (APW13) (Ramboll, 2023). The locations of these wells and measured bedrock elevations indicate the bedrock surface is highest in the southeast portion of the site and slopes downward to the west and north beneath the PAP.

2.3.2 Uppermost Aquifer

The UA includes the Mulberry Grove Member in the vicinity of the PAP. Groundwater monitoring for the UA is focused on this zone because it is continuous, exhibits moderate permeability, and is likely to indicate potential impacts from the PAP. The top of UA was evaluated with respect to the location restrictions in 2018 [7] and provided in **Figure 2-6**. Based on the geologic information, the top of the aquifer is highest in elevation nearest the base of the CCR in the eastern portion of the pond (along a NW-SE trending line between APW05 to APW10), with an elevation of approximately 482 feet. The top of the UA is separated from overlying CCR material by the low permeability Vandalia Till which was encountered at thicknesses up to 59 feet and an average thickness of 26 feet (**Figures 2-7** to **2-9**). The base of the UA is the top of the LCU, which contains the low permeability Smithboro Till and the Banner Formation.

[1] All elevations in this report are referenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

2.3.3 Potential Migration Pathways

The UD consists mostly of low permeability clays and silts of the Peoria Silt, Sangamon Soil, and sandy clay of the Hagarstown Member which also includes discontinuous sand lenses. Monitoring wells APW02, APW03, and APW04 are screened in sandy clay at the interface with the Vandalia Till, while APW05S and APW12 are screened within the sandier deposits of the UD. These wells are generally screened at similar elevations and provide representative groundwater samples to monitor shallow PMPs adjacent to the PAP.

2.3.4 Regional Bedrock Geology

Bedrock investigation at the site has been limited given the depth to bedrock, presence of low permeability confining units underlying the UA and above the bedrock, the low permeability of the bedrock unit, and generally non-potable groundwater. There are no known monitoring wells or production wells screened within the bedrock at NPP. Bedrock has been encountered at three borings on-site (APW13, APW14, and historic boring B141), with elevations ranging from 408 feet (B141) to 445 feet (APW13). A literature review was completed to supplement the site geology. Groundwater available from bedrock units is mostly mineralized and rarely used as a source for potable water [8]. Lithium is naturally occurring in shale bedrock and overlying regolith and is released to groundwater during weathering processes [9]. Regional investigations of the Illinois Basin have also identified bedrock (specifically brines within the bedrock formations) as a source of chloride in groundwater [10, 11]. Studies by Cartwright [12] and Siegel [13] indicate that groundwater migrates toward the center of the Illinois Basin and discharges upward through overlying confining units. The "Saline groundwater and brines can be brought near or to the land surface by natural conditions, such as migrating up prominent fractures and/or faults in bedrock, or by anthropogenic activities, such as exploration for and exploitation of petroleum. The mixing of upward-migrating saline groundwater with fresh groundwater from shallow aquifers can make groundwater from private wells undrinkable and can present a very expensive problem for municipalities" [14]. A saline spring was identified in Clay County [10] approximately 10 miles south of the NPP and is adjacent to the Clay City Anticline which runs north into Jasper County and east of the NPP. Concentrations of chloride in groundwater collected from the Pennsylvanian shale in Jasper County range from 100 to 5,000 milligrams per liter (mg/L) [11].

2.3.5 Water Table Elevation and Groundwater Flow Direction

The elevations of water within the PAP (as observed in XPW01 through XPW04, and XSG01) are greater than the surrounding areas. The phreatic surface within the PAP in 2023 averaged 539 feet, ranging from approximately 547 feet in XPW02 (located along the northern portion of the PAP) to 530 feet in XSG01 (staff gage located along the southern portion of the PAP) (**Figure 2-10)**.

As indicated in Section 2.3.2 the groundwater in the UA is separated from overlying CCR material by an average thickness of 26 feet of the low permeability Vandalia Till. Groundwater flow in the UA is generally from the north near background wells APW05 and APW06 to the southwest toward a historic drainage feature and southeast toward Newton Lake. Specifically, groundwater flow is north to south beneath the center of the PAP (from APW05/APW06 toward APW09/APW15). Beneath the western portion of the PAP, flow is west to southwest converging towards a former surface drainage feature located west of the PAP (**Figure 2-10**) and an area where the UA is lowest in elevation and has the highest hydraulic conductivity. Beneath the eastern portion of the PAP, groundwater flows east to southeast (from APW05 toward APW11-

APW14). Groundwater elevations exhibit limited variability, generally less than one to two feet per year. Spatially across the PAP they range from approximately 490 feet in the southern portion of the site to 530 feet in the northern portion of the site. Flow directions are generally consistent between seasons [5].

Groundwater elevations in PMP wells are above those in the UA, exhibit more variability, (1-4 feet per year), and range from approximately 518 feet (APW05S) to 535 feet (APW05S). Groundwater elevations within the UCU, LCU, and bedrock unit are unknown because no wells are screened within these low hydraulic conductivity units. Groundwater flow within the aquitards of the UCU and LCU will be primarily vertical based on heads above and below these units.

2.3.5.1 Vertical Hydraulic Gradients

Vertical hydraulic gradients calculated using available groundwater elevation data from February to August 2021 at nested well locations within the UD (*i.e.,* PMP) and UA wells indicated downward gradients [5], which was consistent with historical results [15]. Recent data collected through April 2023 is also consistent with these results. The results of the vertical hydraulic gradient calculations for these hydrostratigraphic units are summarized below:

- UD (*i.e.,* PMP) to UA:
  - Gradients calculated between APW05S (PMP) and APW05 (UA) were downward for all events.
  - Gradients calculated between APW04 (PMP) and APW10 (UA) were downward for all events.
  - Gradients calculated between APW03 (PMP) and APW09 (UA) were downward for all events.
  - Gradients calculated between APW02 (PMP) and APW17 (UA) were downward for all events.

2.3.5.2 Impact of Surface Water Bodies on Groundwater Flow

The surface water elevation at Newton Lake measured from February 15, 2021 to October 9, 2023 ranged from 503.56 to 504.84 feet at location SG02 near the outfall from the Secondary Pond. Groundwater flow in the UA generally flows southwest across the PAP with potentiometric surface elevations at downgradient wells around 491 feet (approximately 10-15 feet lower than the Newton Lake elevation). The separation observed in groundwater and surface water elevations (and observed downward vertical gradients) indicates groundwater within the UA does not flow into Newton Lake along the western portion of the site.

Groundwater elevations observed at APW10 located on the east side of the site are approximately 2 feet higher than surface water in Newton Lake (506 feet versus 504 feet) indicating groundwater migrates toward the Lake along the eastern boundary of the Unit. Based on the stratigraphic interpretations, the UA slopes upward in this area and approaches the former land surface, now beneath Newton Lake. As illustrated in cross-section B-B' (**Figure 2-8**), the UA may intersect the base of Newton Lake.

2.3.6 Hydraulic Conductivities

2.3.6.1 Field Hydraulic Conductivities

Field hydraulic conductivity tests were conducted by Ramboll during the 2021 investigation [5]. The results are summarized in **Table 2-1**, and discussed below:

- **CCR**: Results of field hydraulic tests in wells screened within the CCR (XPW01 through XPW04) ranged from 1.0×10^{-3} to 2.3×10^{-1} centimeters per second (cm/s), with a geometric mean of 2.0×10^{-2} cm/s.
- **UD**: Previous field hydraulic conductivity tests conducted by NRT in 2017 in wells screened within the Sangamon Soil of the UD (APW02, APW03, and APW04) ranged from 5.14×10^{-6} to 4.53×10^{-5} cm/s, with a geometric mean hydraulic conductivity of 1.5×10^{-5} cm/s [15].
  - **PMP**: Results of field hydraulic tests in wells screened within the Hagarstown PMP (APW05S and APW12) ranged from 6.1×10^{-4} to 1.5×10^{-2} cm/s, with a geometric mean hydraulic conductivity of 3.1×10^{-3} cm/s.
- **UCU**: No field hydraulic conductivity tests were performed as there are no wells screened within the UCU.
- **UA**: Results of field hydraulic tests in wells screened within the UA (APW11, APW13, APW14, APW15, APW16, APW17, and APW18) ranged from 2.0×10^{-4} to 1.5×10^{-1} cm/s, with a geometric mean of 6.8×10^{-3} cm/s. Previous field hydraulic conductivity tests conducted in 2017 obtained similar results with a geometric mean hydraulic conductivity of 1.2×10^{-3} cm/s [15]. The highest conductivities are measured in APW15, APW16, and APW17, which is consistent with groundwater flow toward these wells. In addition, the grain-size analyses of the UA materials from two samples collected at APW17 were amongst the highest observed at the Site, with sand and gravel contents of 91.1 and 93.3 percent.
- **LCU**: No field hydraulic conductivity tests were performed as there are no wells screened within the LCU.
- **Bedrock**: No field hydraulic conductivity tests were performed as there are no wells screened within the bedrock unit.

2.3.6.2 Laboratory Hydraulic Conductivities

Falling head permeability tests (ASTM D5084 Method F) were performed in the laboratory on samples collected during the 2021 investigations [5]. The results are summarized in **Table 2-2** and discussed below.

- **CCR**: Eight samples were collected from CCR borings XPW01 through XPW04, located within the PAP. However, the two samples collected from XPW02 (8 to 8.5 and 16.5 to 17 feet bgs) were general fill not CCR fill and are not included in summary of CCR characteristics. Laboratory falling head permeability test results for the six CCR samples indicated a geometric mean vertical hydraulic conductivity of 3.1×10^{-4} cm/s with a range of 1.6×10^{-5} to 1.3×10^{-3} cm/s.
- **UD**: One sample was collected from the Sangamon Soil at borings APW11 and APW15. Laboratory falling head permeability test results in the UD indicated a geometric mean vertical hydraulic conductivity of 5.9×10^{-8} cm/s and ranged from 3.1×10^{-8} to 8.6×10^{-8}

cm/s. These values are lower than previous samples collected in 2017 from APW02 AND APW04, which reported a geometric mean hydraulic conductivity of 1.3 x 10^{-5} cm/s [15].

- **PMP**: Three samples were collected from the Hagarstown Member, a PMP within the UD, at borings APW12 and APW13. Laboratory falling head permeability test results for the Hagarstown Member indicated a geometric mean vertical hydraulic conductivity of 3.5 x 10^{-5} cm/s and ranged from 1.1 x 10^{-7} to 9.6 x 10^{-5} cm/s.
- **UCU**: Four samples were collected from the Vandalia Till at borings APW14, APW17, SB300/APW18, and SB301. Laboratory falling head permeability test results for the UCU samples indicated a geometric mean vertical hydraulic conductivity of 6.7 x 10^{-8} cm/s and ranged from 3.3 x 10^{-8} to 9.7 x 10^{-8} cm/s. These values are similar to a previous investigation completed in 1997 that reported hydraulic conductivity values ranging from 6.3 x 10^{-9} to 2.1 x 10^{-8} cm/s with a geometric mean hydraulic conductivity of 1.1 x 10^{-8} cm/s [8].
- **UA**: Five samples were collected from the Mulberry Grove Formation at borings APW13, APW15, APW17, and APW18. Laboratory falling head permeability test results for the Mulberry Grove Formation indicated a geometric mean vertical hydraulic conductivity of 3.2 x 10^{-4} cm/s and ranged from 3.5 x 10^{-6} to 7.2 x 10^{-4} cm/s.
- **LCU**: Eight samples were collected from the glacial tills of the Smithboro Till at borings APW11, APW12, APW14, APW15, APW18, and SB301. Laboratory falling head permeability test results for the Smithboro Till indicated a geometric mean vertical hydraulic conductivity of 9.3 x 10^{-8} cm/s and ranged from 2.4 x 10^{-8} to 2.7 x 10^{-7} cm/s. No samples were collected from the Banner Formation of the LCU.
- **Bedrock**: No bedrock samples were analyzed.

2.4 Groundwater Monitoring

The monitoring system for the PAP is shown on **Figure 2-2** and consists of two background monitoring wells (APW05 and APW06), 16 compliance monitoring wells (APW02, APW03, APW04, APW05S, APW07, APW08, APW09, APW10, APW11, APW12, APW13, APW14, APW15, APW16, APW17, and APW18), and two temporary water level only surface water staff gages (XSG01 and SG02) to monitor potential impacts from the PAP [16]. These monitoring wells are screened within the UD/PMP (APW02, APW03, APW04, APW05S, and APW12) and the UA (APW05, APW06, APW07, APW08, APW09, APW10, APW11, APW13, APW14, APW15, APW16, APW17, and APW18) along the perimeter of the PAP. Porewater samples are collected from locations XPW01 and XPW02 on the northern side of the PAP, and from XPW03 and XPW04 on the northeastern side of the PAP (**Figure 2-2**).

2.5 Hydrogeologic Conceptual Site Model

The HCR [5] and information provided above forms the foundation of the PAP hydrogeological setting. The PAP overlies a potential recharge area for the underlying transmissive geologic media, which are composed of unlithified deposits. Recharge migrates downward into and through the UD and UCU into the UA. In locations where recharge intersects the Hagarstown, it mixes with groundwater and migrates within the unit, which is also monitored as a PMP in addition to the UA.

The silts of the UD and sands of the PMP are hydraulically connected and considered a single hydrostratigraphic unit although groundwater migration will be variable based on localized

hydraulic properties. The groundwater flow in the silts and clays of the UD and confining units of the UCU, LCU, and BCU is expected to be primarily vertical. The Hagarstown member PMP and sands of the UA are the primary units where the majority of the horizontal groundwater migration is expected to occur. The geologic conceptual model for the site used for the groundwater modeling [17] consists of the following layers:

- Silts and Clays (UD) – silt and clayey silt of the Peoria Silt and Sangamon Soil which extends beneath the topsoil.
- Discontinuous sands (PMP) – sandier soils of the Hagarstown Member.
- Vandalia Till (UCU) – a thick layer of low permeability till consisting of the Vandalia Till.
- Sands (UA) – sands and gravels of the Mulberry Grove Formation, laterally continuous sand and gravel deposit identified beneath the site.
- Smithboro Till (LCU) – composed of lean clay Smithboro Till and Banner Formation.
- BCU – lowermost unit identified at the site and underlies all unlithified deposits. This unit is composed of low permeability shale of the Mattoon Formation.
- Alluvial deposits of the Cahokia formation may replace UD and UCU deposits along the southeastern boundary of the PAP.

The United States Geological Survey (USGS) National Map places the NPP within the upper Illinois-Little Wabash watershed subbasin (Hydrologic Unit Code 05120114). The PAP hydrogeologic CSM extent is bounded by a hydrological catchment (watershed) divide to the east based on watershed data from USGS. The Newton Lake water levels are managed such that they remain at an elevation between 504.23 and 504.82 feet. Newton Lake is the receiving body of water for surface water.

Precipitation infiltrates and recharges the groundwater table throughout the site and upgradient. Groundwater in the UD migrates downward into the discontinuous sands of the Hagarstown Formation. The Hagarstown Formation, where present, is considered a PMP for groundwater adjacent to the PAP and localized lateral migration of groundwater may occur. The sands of the UA are separated from the Hagarstown Formation PMP and the base of CCR in the PAP by the laterally continuous low permeability UCU. The UA receives water from the overlying geologic units and potentially through its interpreted connection with Newton Lake. Water that percolates downward from layers overlying the UA is most likely to travel laterally from the site within the UA due to the lateral continuity, relatively high permeability, and horizontal gradients present within the UA as described above. Further downward migration is also limited by the relatively thick and low permeability LCU.

Based on the geology and hydrogeology, monitoring wells at the PAP can be separated into three distinct groupings which exhibit similar geologic and hydraulic characteristics. Monitoring well groupings are summarized as follows:

- UD/PMP wells: shallow wells (generally less than 40 feet bgs) screened in low to moderate permeability materials (generally $\leq 10^{-4}$ cm/s) including APW02, APW03, APW04, and APW05S. Based on the water levels measured within the PAP, UD/PMP wells are downgradient of the PAP.

Eastern UA wells: wells located on the eastern half of the PAP (APW05, APW10, APW11, APW13, and APW14) where the top of the UA is slightly shallower (~40 to 60 feet bgs). Results indicate that the hydraulic conductivity of the UA is lowest where the UA is shallowest at monitoring wells APW05 and APW10. Groundwater flow directions indicate these wells are currently downgradient of the former drainage feature that was present prior to construction of the PAP.

- Western UA wells: wells located on the western half of the PAP (APW06, APW07, APW08, APW15, APW16, APW17, and APW18) where the top of the UA is slightly deeper (~60 to 90 feet bgs). Several of these wells had high hydraulic conductivities. Groundwater flow directions indicate these wells represent groundwater from the western portion of the PAP and from areas located west of the PAP.

3. OCCURRENCE AND DISTRIBUTION OF GROUNDWATER EXCEEDANCES (EXTENT)

Results from groundwater samples collected from the PAP during E001 were received on June 8, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), comparison of statistically derived values with the GWPSs described in 35 I.A.C. § 845.600 to determine exceedances of the GWPS was completed [2]. Exceedances for which an ASD was not completed include the following parameters and wells by hydrostratigraphic unit:

- UA (**Figure 3-1**):
  - Sulfate at APW10
- UD (PMP; **Figure 3-2**):
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - TDS at APW02, APW04, and APW05S

3.1 Additional Investigation to Define Nature and Extent

Following initial sampling in 2021, potential exceedances of the GWPS were identified for the parameters and locations identified above [18]. Additional investigation was completed in 2021 to collect soil samples and surface water samples to further evaluate the concentrations and potential attenuation mechanisms near the PAP (**Appendix A** and **Appendix B**).

A total of seven borings were advanced adjacent to locations with potential exceedances (APW02, APW04, APW05S, and APW10), and porewater wells (XPW01 and XPW04). Solids samples were collected and analyzed for the following:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld x-ray diffraction (XRD) Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

In addition, 28 surface water samples were collected to characterize the water quality in Newton Lake. Surface water samples were analyzed for 35 I.A.C. § 845.600 parameters (total and dissolved), ferrous and ferric iron, major ions, and monitored natural attenuation parameters. Data from this investigation has been incorporated into this report where applicable.

3.2 Extent in the Uppermost Aquifer

Groundwater samples are evaluated quarterly and exceedances are identified following comparison of lower confidence limits (LCLs) to the GWPSs described in 35 I.A.C. § 845.600. The

LCLs vary as the dataset is updated to include additional quarterly events (**Table 3-1**). The discussion below includes ranges of concentrations measured in wells with exceedances, because there is no single value for LCLs.

3.2.1 Sulfate

Sulfate exceedances in the UA are limited to APW10. Monitoring well APW10 is located on the southeast berm of the unit, between the PAP and Newton Lake. Concentrations of sulfate in APW10 range from 390 to 540 mg/L. The extents of concentrations above the GWPS are defined laterally in the UA to the southwest by monitoring well APW13 (**Figure 3-1**). The boring log from APW12 (location shown on **Figure 2-10**) indicates that the UA is not present northeast of APW10, and exceedances are not expected to extend a significant distance in this direction due to observed groundwater flow directions and the absence of UA materials observed at APW12. Newton Lake is located approximately 100 feet downgradient of APW10 and comparison of water elevations indicates that groundwater migrates toward Newton Lake. The extent of sulfate is defined downgradient by surface water samples collected near APW10 which indicate concentrations of sulfate are 39 mg/L (**Appendix B**), comparable to concentrations measured for sulfate in ambient portions of the lake distant from the PAP.

Downward migration of sulfate in the UA at APW10 is inhibited by the underlying Smithboro Till which has a thickness of greater than 10 feet. Vertical permeability tests completed on samples of the LCU beneath the UA indicate a geometric mean vertical hydraulic conductivity of 9.3×10^{-8} cm/s with a range from 2.4×10^{-8} to 2.7×10^{-7} cm/s. This is very low relative to the horizontal hydraulic conductivity measured within APW10 (5.5×10^{-4} cm/s). The significant contrast in permeability (greater than two orders of magnitude) indicates groundwater will preferentially migrate horizontally toward Newton Lake and the elevated sulfate concentrations will not extend into the underlying till and shale bedrock.

3.3 Extents in Upper Drift /Potential Migration Pathways

3.3.1 Sulfate

Concentrations of sulfate exceed the GWPS (400 mg/L) at UD/PMP wells APW02, APW04, and APW05S. Concentrations and the extent of sulfate at these locations (**Figure 3-2**) are summarized as follows:

- APW02 – Concentrations range from 1,500 to 3,200 mg/L. The lateral and downgradient extent of sulfate concentrations near APW02 is currently being investigated but is ultimately limited downgradient by Newton Lake. Concentrations of sulfate in Newton Lake near this location were 38 mg/L (**Appendix B**), comparable to concentrations measured for sulfate in ambient portions of the lake distant from the PAP. Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low sulfate concentrations reported in APW17 (non-detect to 64 mg/L) which is nested with APW02 and screened in the UA beneath the PMP.
- APW04 – Concentrations range from 760 to 990 mg/L. The lateral extent of sulfate concentrations in the UD near APW04 is defined to the north by APW12 (56 to 712 mg/L) and to the southwest by APW03 (110 to 190 mg/L). APW04 is located approximately 100 feet from Newton Lake. As discussed for APW10, concentrations of sulfate in the adjacent area of

Newton Lake were 39 mg/L. Vertical extents at this location were discussed in the previous section regarding APW10.

- APW05S – Concentrations range from 200 to 2,100 mg/L. The lateral and downgradient extent of sulfate concentrations near APW05S is currently being investigated to the north and east but is defined by APW12 (56 to 712 mg/L) to the east. Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (range of 6.3×10^{-9} to 9.7×10^{-8} cm/s measured in the till onsite). Lack of vertical migration is also supported by the low sulfate concentrations reported in APW05 (non-detect at 15 mg/L) which is nested with APW05S and screened in the UA beneath the PMP.

3.3.2 Lithium

Monitoring well APW02 is located near the southwest corner of the PAP and screened within the low conductivity materials of the UD. Concentrations of lithium range from 0.079 to 0.3 mg/L. The lateral and downgradient extent of lithium concentrations near APW02 is limited downgradient by Newton Lake and additional data is currently being collected to further evaluate the extent of lithium and sulfate concentrations in groundwater. Concentrations of lithium were not detected in Newton Lake near this location (<0.02 mg/L; **Appendix B**). Vertically, the extent of lithium is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low lithium concentrations reported in APW17 (non-detect to 0.0099 mg/L) which is nested with APW02 and screened in the UA beneath the PMP.

3.3.3 Total Dissolved Solids

TDS results indicate the mass of dissolved material in the groundwater and is a representation of multiple constituents present in the groundwater. Typically, major ions (such as sulfate) represent the primary contributors to TDS. TDS exceeded the GWPS at APW02 and APW04. Concentrations and the extent of TDS at these locations is summarized as follows:

- APW02 – Concentrations range from 1,910 to 5,500 mg/L. The lateral and downgradient extent of TDS concentrations near APW02 is currently being investigated but is limited downgradient by Newton Lake. Concentrations of TDS in Newton Lake near this location were 170 mg/L (**Appendix B**). Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low TDS concentrations reported in APW17 which is nested with APW02 and screened in the UA beneath the PMP.
- APW05S - Concentrations range from 3,200 to 4,000 mg/L. The lateral and downgradient extent of TDS concentrations near APW05S is currently being investigated to the north and east but is defined by APW12 (990 to 1,740 mg/L) to the east. Vertically, the extent of TDS is limited by the low permeability Vandalia Till which underlies this well (range of 6.3×10^{-9} to 9.7×10^{-8} cm/s measured in till onsite) and is supported by the low TDS concentrations reported in APW05 (470 to 1,000 mg/L) which is nested with APW05S and screened in the UA beneath the PMP. Concentrations above the GWPS do not extend past the waste boundary downgradient as evidenced by concentrations in wells APW03 and APW04.

4. GEOCHEMICAL CONCEPTUAL SITE MODEL (NATURE)

A GCSM was developed to describe the conditions of the groundwater in the vicinity of the NPP PAP and is summarized here (full analysis presented in **Appendix C**). The GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. Only parameters that have exceeded the GWPS in PAP groundwater and will be addressed in the corrective action plan are included in the GCSM. As discussed in previous sections the exceedances observed at the PAP include sulfate, TDS, and lithium.

The GCSM includes two hydrostratigraphic units: the shallow UD/PMP and the deeper UA. The UA is shallowest (*i.e.*, in closest proximity to the upper drift/primary migration pathway) on the east side of the PAP. Groundwater in the UD/PMP and eastern UA wells tend to be geochemically similar: groundwater from these locations tends to be more oxidizing, exhibit lower pH, and have a cation signature dominated by calcium and magnesium. Groundwater in the rest of the UA tends to be more reducing (exhibiting higher dissolved iron concentrations), have higher pH, and have a greater contribution of sodium and potassium to the cation signature. These results suggest some degree of hydraulic connection between the UD/PMP and UA east of the PAP.

Sulfate is the major contributor to TDS in the PAP groundwater. Therefore, processes that control sulfate concentrations also control TDS. Elevated sulfate concentrations were observed in shallow groundwater wells (screened in the upper drift/primary migration pathway) and UA wells located east of the PMP. Sulfate in CCR porewater and the UD/PMP groundwater is correlated with sodium, indicating that dissolution of sodium sulfate from the CCR material is the primary source of sulfate to the CCR porewater. Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. Potential sulfate attenuation mechanisms at the NPP PAP include sorption to solid-phase iron oxides. Based on results from laboratory batch testing, sulfate sorption may be more likely in the UA.

Lithium concentrations in groundwater are highest in UD/PMP and eastern UA groundwater. Although lithium was identified in solid samples located both upgradient and downgradient of the PAP, the similar distributions of lithium and sulfate suggest that CCR porewater is the primary source of lithium to the groundwater. The difference in groundwater lithium concentrations may be due to variability in porewater concentration or in attenuation to aquifer solids. Lithium in groundwater may be attenuated by sorption to exchangeable sites (readily reversible) or incorporation in clay mineral matrices (poorly reversible). According to results from laboratory batch testing, lithium may sorb to both UA/PMP and UA solids.

5. COMBINED GEOCHEMICAL AND HYDROGEOLOGIC CONCEPTUAL SITE MODELS

5.1 Sulfate and TDS Conceptual Site Model

The CSM describing current conditions at the PAP combining the hydrogeologic and geochemical CSMs for sulfate and TDS is as follows. Surface water within the PAP comes into contact with CCR and once it enters the pore spaces within the CCR we characterize it as porewater within the unlined CCR unit. Porewater containing elevated concentrations of sulfate mixes with groundwater of the UD. Groundwater within the UD/PMP in the vicinity of the PAP travels horizontally outward from the PAP, ultimately migrating toward Newton Lake, or vertically into the clay of the UCU that separates the UD from the UA. Sulfate concentrations are attenuated physically through dilution and dispersion; and may be geochemically attenuated by sorption to iron oxides. The limit of sulfate exceedances is defined by wells in the UA with concentrations below the GWPS and Newton Lake, where sulfate concentrations near APW10 are 39 mg/L (**Appendix B**). The sulfate concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1]. Sulfate exceedances of the GWPS have been observed in 3 of 5 UD wells and 1 of 13 UA wells. The presence or absence of exceedances can be attributed to variability in both sulfate concentration within the CCR of the PAP and the extent of water migration between the UD/PMP and UA.

5.2 Lithium Conceptual Site Model

The CSM describing current conditions at the PAP combining the hydrogeologic and geochemical CSMs for lithium is as follows. Surface water within the PAP comes into contact with CCR and once it enters the pore spaces within the CCR we characterize it as porewater within the unlined CCR unit. Porewater containing elevated concentrations of lithium mixes with groundwater of the UD/PMP. Groundwater within the UD in the vicinity of the PAP travels horizontally outward from the PAP, ultimately migrating toward Newton Lake, or vertically into the clay of the UCU that separates the UD from the UA. Lithium concentrations are attenuated physically through dilution and dispersion and may be geochemically attenuated by sorption to and incorporation into clay minerals. The lithium exceedance is limited to one location (APW02) and is being further investigated laterally, but is limited in extent by Newton Lake, where concentrations in surface water were < 0.02 mg/L (**Appendix B**). The lithium concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1]. Lithium exceedances of the GWPS have only been observed in UD well APW02 located along the western side of the PAP, which is the same side of the PAP where the highest concentrations of lithium were observed in porewater (XPW01), indicating exceedances at APW02 may be a result of proximity to portions of the PAP where CCR porewater contains relatively higher concentrations of lithium.

6. CONCLUSIONS AND FUTURE ACTIVITIES

In accordance with 35 I.A.C. § 845.650(d)(1), the nature and extent of GWPS exceedances of sulfate, TDS, and lithium have been described in sufficient detail to support a complete and accurate assessment of the corrective measures necessary to effectively clean up all releases from the PAP.

The lateral extents of exceedances are illustrated in **Figures 3-1 and 3-2**. As discussed in Sections 3.3.1 and 3.3.2, the horizontal delineation of lithium at APW02 is ongoing, as well as additional characterization of sulfate exceedances at APW04, APW05S, and APW10. Wells will be installed upgradient of APW05S; downgradient of APW02, APW04, and APW10; and along the NEW PAP waste boundary, adjacent to APW02 in 2024. Findings from the installation and sampling of these additional wells will be incorporated into the final Corrective Action Plan Permit application, which will be submitted in 2025.

Sulfate was selected for modeling source control presented in the Final Closure Plan and was identified as a surrogate for the exceedances of lithium and TDS, as described in the Groundwater Modeling Report (GMR) [17]. For modeling purposes it was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]), which is a conservative estimate for predicting contaminant transport times in the model. Additional geochemical modeling will be completed to evaluate how sorption to solid phases may affect sulfate and lithium mobility and therefore the time to reach the GWPS for these parameters.

Notes:
[1] Porosity calculated as relationship of bulk density to particle density (n = 100[1- (pb/pd)])
% = Percent
bgs = below ground surface
CCR = coal combustion residuals
cm/s = centimeters per second
ft = foot/feet
in = inch
LL = Liquid limit
NP = Non Plastic
pcf = pounds per cubic foot
PI = Plastic Index
PL = Plasticity Limit

HSU = Hydrostratigraphic Unit
LCU = lower confining unit
PMP = potential migration pathway
UA = uppermost aquifer
UCU = upper confining unit
UD = upper drift

USCS = Unified Soil Classification System
CL - Lean Clay
CL-ML = Silty Lean Clay
SC = Clayey Sand
SM = Silty Sand
SP-SM = Poorly Graded Sand with Silt
SW-SM = Well Graded Sand with Silt

APPENDIX A
Technical Memorandum - Monitored Natural Attenuation Field Investigation Status Update

GOLDER
MEMBER OF WSP

TECHNICAL MEMORANDUM

DATE December 15, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company (IPGC)

CC Brian Hennings - Ramboll

FROM Pat Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

MONITORED NATURAL ATTENUATION FIELD INVESTIGATION STATUS UPDATE, PRIMARY ASH POND (CCR UNIT 501) NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

The following Technical Memorandum summarizes the results received to date from the Monitored Natural Attenuation (MNA) Field Investigation completed by Golder Associates USA Inc. (Golder) for the Primary Ash Pond (PAP, CCR Unit 501) located at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. Data collected as a part of this investigation will be an integral part of the MNA Feasibility Demonstration for the PAP and will be used for IPGC's Illinois Part 845 Coal Combustion Residual (CCR) compliance program. A Site plan showing the PAP, existing Part 845 monitoring wells, and the MNA boring locations is provided in **Figure 1**.

This memorandum only includes laboratory analytical data that has been received to date. Golder will update this memorandum when the remaining data has been received and reviewed.

2.0 PROJECT SCOPE OF WORK

As part of the MNA Feasibility Demonstration, and ongoing discussions with IPGC, Golder completed the following activities as part of this Field Investigation:

- Screened for potential underground utilities in the vicinity of the proposed borings prior to completing any drilling or ground disturbance activities.
- Advanced a total of seven (7) soil borings ranging in depth from 15 to 90 feet below ground surface (ft bgs).
- Collected ten (10) soil samples from seven (7) soil borings for laboratory analysis.
- Collected groundwater samples from five (5) existing monitoring wells for laboratory analysis.

3.0 FIELD INVESTIGAITON

3.1 Private Utility Locate

Prior to conducting any work onsite, Golder reviewed Site plans/drawings provided by IPGC and/or Site representatives and met with Site representatives to assist in identifying underground utility locations in the vicinity

Golder Associates Inc.
13515 Barrett Parkway Drive, Suite 260, Ballwin, Missouri, USA 63021 T: +1 314 984-8800 F: +1 314 984-8770

of the proposed borings. Golder also sub-contracted with GPRS to provide ground penetrating radar (GPR) and electromagnetic (EM) tracing services to screen the proposed boring locations in the field. All boring locations were cleared by GPRS personnel before drilling commenced.

3.2 Drilling and Aquifer Solids Sampling

Drilling was completed by Cascade Environmental Drilling (Cascade) using a roto-sonic drill rig under direct supervision of a Golder Geologist from August 17 – 21, 2021. Continuous soil core samples were obtained at each borehole location and were logged in the field by Golder personnel. Soils were classified according to the Unified Soil Classification System (USCS) and in accordance with the standard Golder Soil Logging Technical Procedure.

During the field investigation, seven (7) soil borings were advanced at the locations shown on **Figure 1**. Soil boring logs are provided in **Attachment A**. The following units were encountered during the field investigation (unit names are consistent with the Groundwater Monitoring Plan (Ramboll, 2021) in the Newton Part 845 Operating Permit):

- Shallow Saturated Zone – This zone is made up of the Upper Drift and the Upper Confining Units. The Upper Drift consists of low permeability silts and clays of the Peoria Silt and Sangamon Soil and the Hagarstown Member (Potential Migration Pathway) which consists of discontinuous sandier deposits. Below the Upper Drift is the Upper Confining unit, which consists of low permeability clay and silt of the Vandalia Till. The contact between the Upper Confining Unit and the underlying Uppermost aquifer ranges from approximately 467 feet above mean sea level (FT MSL) to 483 FT MSL in the borings completed for this investigation. Samples from the shallow saturated zone are shown in **Table 1**.
- Uppermost Aquifer – This zone consists of the Mulberry Grove Formation and is generally made up of fine to coarse, poorly to well graded sands, with occasional clayey sand layers and gravels. The formation is present between approximately 449 and 483 FT MSL. Samples collected from the uppermost aquifer are shown in **Table 1**.
- Lower Confining Unit – This unit consists of the Smithboro Till and is generally made up of compact glacial till consisting of low permeability silty clays and clayey silts with trace sand and gravel. The Till was present directly below the Uppermost Aquifer and the contact between these two units ranges from approximately 449 FT MSL to 474 FT MSL. Drilling was terminated in the Lower Confining Unit in most boreholes, therefore, evaluation of the full thickness of the unit was not completed as a part of this investigation. There were no samples collected from the lower confining unit.

Methane was encountered in soil boring SB-02, on August 18, 2021, while retrieving the soil from 60 to 80 feet below ground surface (FT BGS) within the bottom of the Shallow Saturated Zone and the top of the Uppermost Aquifer unit. Drilling was stopped until methane levels dropped below safe working levels and continued on August 19, 2021. Methane was only detected in this borehole during this investigation.

Ten (10) soil samples were collected for laboratory analysis from the soil borings (see **Figure 1** for sample location). Details regarding collected samples are included in **Table 1**.

Table 1: Laboratory Soil Sample Locations and Intervals Used for Laboratory Analysis

Borehole ID	Sample ID	Sample Depth (FT BGS)	Soil Type / Geologic Unit Sampled
N-SB-02	N-SB-02 (12.5 – 20.0)	12.5 - 20.0	Clayey Silt / Shallow Saturated Zone
	N-SB-02 (65.0 – 71.5)	65.0 – 71.5	Well Graded Sand /Uppermost Aquifer
N-SB-04	N-SB-04 (12.0 – 18.0)	12.0 – 18.0	Sandy Silty Clay / Shallow Saturated Zone
	N-SB-04 (38.8 – 45.4)	38.8 – 45.4	Clayey Sand / Uppermost Aquifer
N-SB-05	N-SB-05 (18.0 – 20.0)	18.0 – 20.0	Poorly Graded Sand / Shallow Saturated Zone
	N-SB-05 (60.0 – 67.1)	60.0 – 67.1	Poorly Graded Sand / Uppermost Aquifer
N-SB-14	N-SB-14 (44.2 – 52.0)	44.2 – 52.0	Sandy Clay / Uppermost Aquifer
N-SB-18	N-SB-18 (77.5 – 80.0)	77.5 – 80.0	Well Graded Sand / Uppermost Aquifer
N-SB-XPW01	N-SB-XPW01 (10.0 – 12.7)	10.0 – 12.7	CCR
N-SB-XPW04	N-SB-XPW04 (10.0 – 15.0)	10.0 – 15.0	CCR

Notes

1) FT BGS – Feet Below Ground Surface.

3.2.1 Soil Laboratory Analysis

Soil samples collected during the field investigation were placed in clean containers and properly labeled with sample location, depth, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to the following laboratories for analysis:

- Eurofins TestAmerica for 7-Step Sequential Extraction; and
- SiREM for the Batch Testing, Total Metals, Reitveld X-Ray Diffraction (XRD), leachability, Cation Exchange Capacity (CEC), and Total Organic Carbon (TOC) analyses.

The following laboratory analyses were conducted for each soil sample:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld XRD Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

Currently, only the results from Test America have been received, and are included in **Attachment B**. A separate Technical Memorandum will be provided when results from SiREM are completed.

3.2.2 Borehole Survey

On September 1, 2021, IngenAE completed a survey of the boring locations including the longitude/latitude of and elevation of each borehole location. Survey information is included in the boring logs in **Appendix A**.

3.3 Groundwater Sampling

Groundwater sampling was completed by Golder personnel on August 31, 2021. Five (5) existing monitoring wells were sampled, provided in **Figure 1**. Groundwater sample locations and adjacent borehole sample intervals for the MNA evaluation are included in **Table 2**.

Table 2: Groundwater Sample Locations

Well ID	Adjacent Borehole Sample
APW-02	N-SB-02 (12.5 – 20.0)
APW-04	N-SB-04 (12.0 – 18.0)
APW-05S (background)	N-SB-05 (18.0 – 20.0)
APW-05 (background)	N-SB-05 (60.0 – 67.1)
APW-14	N-SB-14 (44.2 – 52.0)

3.3.1 Groundwater Sample Laboratory Analysis

Groundwater samples collected during the field investigation were placed in clean containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to SiREM Laboratories to be included in batch testing analysis along with soil samples collected at adjacent boreholes. Results for the batch testing has not yet been completed and will be provided in a separate Technical Memorandum.

4.0 CLOSING

Golder appreciates the opportunity to serve as your consultant on this project. If you have any questions concerning this technical memorandum or need additional information, please contact the undersigned

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

APPENDIX B
Technical Memorandum – Surface Water Sampling

GOLDER
MEMBER OF WSP

TECHNICAL MEMORANDUM

DATE December 16, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company

FROM Patrick J. Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

SURFACE WATER SAMPLING SUMMARY, NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

Golder Associates USA Inc. (Golder) is pleased to submit this Technical Memorandum summarizing recent surface water sampling activities at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. During the field investigation, 28 samples were collected and sent for laboratory analysis from Newton Lake, which is adjacent to the Site, in the vicinity of the Primary Ash Pond (PAP, CCR Unit ID 501). A sample location map is provided in **Figure 1**.

2.0 PROJECT SCOPE OF WORK

The scope of work for this project consisted of the following:

- Preparation of a Site-specific Health, Safety, and Environment Plan (HASEP).
- Review of baseline data to determine sample locations and constituents for analysis.
- Collection of 28 surface water samples from Newton Lake.
- Preparation of a Technical Memorandum to summarize the sampling and the results.

3.0 FIELD INVESTIGATION

3.1 Health, Safety, and Environment Plan

This work was performed under a Site-Specific HASEP that was approved by IPGC. The HASEP was prepared in accordance with IPGC sub-contractor requirements and includes identification of occupation and health and safety hazards (risks) related to the field team, site conditions, specific risk controls, training requirements, personal protective equipment (PPE) requirements, and information on potential emergencies.

3.2 Surface Water Sampling Locations

Surface water sampling on Newton Lake was completed on October 4th and October 5th, 2021. To access the sample locations, Golder subcontracted with Environmental Restoration, LLC. (ER) to provide and operate an open boat with a low horsepower outboard motor. Twenty-eight (28) surface water samples were collected from Newton Lake at locations agreed upon prior to sampling between Golder and IPGC. Sample locations were

Golder Associates Inc.
13515 Barrett Parkway Drive, Suite 260, Ballwin, Missouri, USA 63021 T: +1 314 984-8800 F: +1 314 984-8770

confirmed in the field using a Trimble Geo7X handheld GPS unit as displayed in **Figure 1**.

3.3 Surface Water Sample Collection and Results

At each sampling location, the field methods described in section 3.2.1.3 of the *Surface Water Sampling Work Plan – Newton Power Plan, Jasper County, Illinois* were completed as applicable. Field parameters including turbidity, pH, specific conductivity, dissolved oxygen, redox potential, and temperature were recorded prior to collecting each sample as shown on the field forms provided in **Appendix A**.

Surface water samples were placed in clean laboratory-supplied containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and the samples and COC were shipped to PDC Laboratories, LLC (PDC) for analysis. Sampling data validation was completed by Golder following receipt of the analytical data from PDC. A summary of the results is displayed in **Table 1** and the laboratory data packet from PDC as well as the data validation is provided in **Appendix B**.

No exceedances of the Site Groundwater Protection Standards (GWPS) used for Part 845 groundwater monitoring were noted based on our initial evaluation of the surface water sampling results. Further evaluation of the surface water data will be completed as part of the MNA evaluation for the site.

4.0 CLOSING

Golder appreciates the opportunity to continue to work on this project. Should you require any additional information about this technical memo, please feel free to contact the undersigned.

Sincerely,

Golder Associates Inc.

Jeffrey Ingram
Senior Project Geologist

Notes:
1. Unit Abbreviations: °C - degrees celcius, µg/L - micrograms per liter, mg/L - milligrams per liter, SU - standard units, mV - millivolts, µS/cm - microsiemens per centimeter, NTU - nephelometric turbidity unit, pCi/L - picocuries per liter, FT BLE - feet below lake elevation.
2. ND - Non Detects. NDs reported as less than the Method Detection Limit (MDL) or adjusted Practical Quanitation Limit (PQL) basd on data validation.
3. Radium (226 + 228) is reported as the sum of the Radium 226 and the Radium 228 activity concentrations unless the sum of the Radium 226 and Radium 228 Minimum Detectable Concentrations (MDC) is higher in which case it is displayed as ND.
4. J - Flags are estimated values based on data validation.
5. Site Groundwater Protection Standards (GWPS) from Table 3-1, Background Groundwater Quality Standards from the Newton Groundwater Monitoring Plan.
6. For pH, the values represent the upper / lower limits. Values outside of these values represents a statistical exceedance.
7. No values are present above the Site GWPS, therefore, no highlighting is used in the table.

Phosphorus, Total	mg/L	NA	ND < 0.05	ND < 0.05	0.068	0.120

Notes:
1. Unit Abbreviations: °C - degrees celcius, µg/L - micrograms per liter, mg/L - milligrams per liter, SU - standard units, mV - millivolts, µS/cm - microsiemens per centimeter, NTU - nephelometric turbidity unit, pCi/L - picocuries per liter, FT BLE - feet below lake elevation.
2. ND - Non Detects. NDs reported as less than the Method Detection Limit (MDL) or adjusted Practical Quanitation Limit (PQL) basd on data validation.
3. Radium (226 + 228) is reported as the sum of the Radium 226 and the Radium 228 activity concentrations unless the sum of the Radium 226 and Radium 228 Minimum Detectable Concentrations (MDC) is higher in which case it is displayed as ND.
4. J - Flags are estimated values based on data validation.
5. Site Groundwater Protection Standards (GWPS) from Table 3-1, Background Groundwater Quality Standards from the Newton Groundwater Monitoring Plan.
6. For pH, the values represent the upper / lower limits. Values outside of these values represents a statistical exceedance.
7. No values are present above the Site GWPS, therefore, no highlighting is used in the table.

SURFACE WATER SAMPLE COLLECTION FORM

Project Ref: Surface Water Sampling - Kincaid & Newton - MNA Evaluation Project No. : 21454831.0004

WEATHER CONDITIONS

Temperature 75°F Weather Clear

SAMPLE INFORMATION

Sample Location N-A-1 Sample No. N-A-1
Sample Date 10/4/21 Time 1115 Sample By EMS
Sample Method Peristaltic Sample Type GRAB

Appearance of Sample: Clear, Some light colored suspended solids
Depth to Bottom of Lake: 0.9 ft
Other Water Sample notes: None

FIELD MEASUREMENTS

Parameter	Units	Measurement	Sample
Time	hhmm	1113	
~~Volume Discharged~~	gals		(ES)
pH	Standard	8.86	
Spec. Cond.	µS/CM	273.6	
Turbidity	NTU	14.7	
Temperature	°C	27.8	
Dissolved Oxygen	mg/l	7.65	
Redox Potential	+/- mV	-15.8	

Northing: 823551.51
Easting: 991516.56
Elevation: 397.83

LABORATORY CONTAINERS

Sub-Sample	Analysis Requested	Type and Size of Sample Container	Filtered (Yes or No)	Type of Preservative
1	Total Metals	1 x 250mL Plastic	NO	HNO_3
2	Dissolved Metals	1x250mL Plastic	Yes	HNO_3
3	Chloride Fluoride Sulfate TDS Alkalinity	1x500mL Plastic	No	None
4	Sulfide	500mL Plastic	No	2N Acetate/NaOH
5	Nitrate	1x500mL Plastic	No	None
6	Total Organic Carbon	3 x 40mL Glass	No	H_2SO_4
7	Phosphorus	1 x 250mL Plastic	No	HNO_3
8	Radium 226 & 228 1x2.5L Plastic	~~2x 1L Plastic~~ (84)	No	HNO_3
9	Ferrous/Ferric Iron	1L Plastic	~~NO~~ Yes (85)	None

SURFACE WATER SAMPLE COLLECTION FORM

Project Ref: Surface Water Sampling - Kincaid & Newton - MNA Evaluation Project No. : 21454831 . 0004

WEATHER CONDITIONS

Temperature 65'F Weather Cloudy

SAMPLE INFORMATION

Sample Location N-UA-2 Sample No. N-UA-2M

Sample Date 10-5-2021 Time 0925 Sample By EMS

Sample Method Peristaltic Sample Type GRAB

Appearance of Sample: Clear-Colorless

Depth to Bottom of Lake: 17.8 ft Sample at 8.9 ft

Other Water Sample notes: None

FIELD MEASUREMENTS

Parameter	Units	Measurement	Sample
Time	hhmm	0925	
Volume Discharged	gals	—	
pH	Standard	9.86	
Spec. Cond.	µ S/CM	276.9	
Turbidity	NTU	12.2	
Temperature	°C	24.2	
Dissolved Oxygen	mg/l	7.22	
Redox Potential	+/- mV	-14.8	

Northing: 823072.73
Easting: 1002564.04
Elevation: 400.80

LABORATORY CONTAINERS

Sub-Sample	Analysis Requested	Type and Size of Sample Container	Filtered (Yes or No)	Type of Preservative
1	Total Metals	1x250mL Plastic	~~No~~	HNO_3
2	Dissolved Metals	〃	Yes	〃
3	Chloride Fluoride Sulfate TDS Alkalinity	1x500mL Plastic	No	Ware
4	Sulfide	〃	〃	Zn Acetate/NaOH
5	Nitrate	〃	〃	None
6	Total Organic Carbon	#3x40mL Glass	〃	H_2SO_4
7	Phosphorus	1x250mL Plastic	〃	HNO_3
8	Radium 226 & 228	1x2.5L Plastic	〃	〃
9	Ferrous/Ferric Iron	1x1L Plastic	~~No~~ Yes	Ware

REMARKS: None

NA = Not applicable

SAMPLING METHODS:

Bailer: Other: Peristaltic Pump

APPENDIX B

Laboratory Analytical Data

November 01, 2021

Jeffrey Ingram
Golder Associates, Inc
13515 Barrett Parkway Dr, Suite 260
Ballwin, MO 63021

RE: GOLDER VISTRA NEWTON

Dear Jeffrey Ingram:

Please find enclosed the **revised** analytical results for the **30** sample(s) the laboratory received on **10/5/21 4:30 pm** and logged in under work order **EJ00598**. All testing is performed according to our current TNI accreditations unless otherwise noted. This report cannot be reproduced, except in full, without the written permission of PDC Laboratories.

If you have any questions regarding your report, please contact your project manager. Quality and timely data is of the utmost importance to us.

PDC Laboratories. appreciates the opportunity to provide you with analytical expertise. We are always trying to improve our customer service and we welcome you to contact the Director of Client Services, Lisa Grant, with any feedback you have about your experience with our laboratory at 309-683-1764 or lgrant@pdclab.com.

Sincerely,

Gail J Schindler

Project Manager
(309) 692-9688 x1716
gschindler@pdclab.com

SAMPLE RECEIPT CHECK LIST

Items not applicable will be marked as in compliance

Work Order EJ00598

YES	Samples received within temperature compliance when applicable
YES	COC present upon sample receipt
YES	COC completed & legible
NO	Sampler name & signature present
YES	Unique sample IDs assigned
YES	Sample collection location recorded
YES	Date & time collected recorded on COC
YES	Relinquished by client signature on COC
YES	COC & labels match
YES	Sample labels are legible
YES	Appropriate bottle(s) received
YES	Sufficient sample volume received
YES	Sample containers received undamaged
NO	Zero headspace, <6 mm present in VOA vials
NO	Trip blank(s) received
YES	All non-field analyses received within holding times
YES	Short hold time analysis
YES	Current PDC COC submitted
NO	Case narrative provided

Revised Report - QC added

Certifications

CHI - McHenry, IL - 4314-A W. Crystal Lake Road, McHenry, IL 60050
TNI Accreditation for Drinking Water and Wastewater Fields of Testing through IL EPA Accreditation No. 100279
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory Registry No. 17556

PIA - Peoria, IL - 2231 W. Altorfer Drive, Peoria, IL 61615
TNI Accreditation for Drinking Water, Wastewater, Solid and Hazardous Material Fields of Testing through IL EPA Accreditation No. 100230
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory Registry No. 17553
Drinking Water Certifications/Accreditations: Iowa (240); Kansas (E-10338); Missouri (870)
Wastewater Certifications/Accreditations: Arkansas (88-0677); Iowa (240); Kansas (E-10338)
Solid and Hazardous Material Certifications/Accreditations: Arkansas (88-0677); Iowa (240); Kansas (E-10338)

SPMO - Springfield, MO - 1805 W Sunset Street, Springfield, MO 65807
USEPA DMR-QA Program

STL - Hazelwood, MO - 944 Anglum Rd, Hazelwood, MO 63042
TNI Accreditation for Wastewater, Solid and Hazardous Material Fields of Testing through KS KDHE Certification No. E-10389
TNI Accreditation for Wastewater, Solid and Hazardous Material Fields of Testing through IL EPA Accreditation No. - 200080
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory, Registry No. 171050
Missouri Department of Natural Resources - Certificate of Approval for Microbiological Laboratory Service - No. 1050

Qualifiers

M	Analyte failed to meet the required acceptance criteria for duplicate analysis.
Q1	Matrix Spike failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q2	Matrix Spike Duplicate failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q3	Matrix Spike/Matrix Spike Duplicate both failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q4	The matrix spike recovery result is unusable since the analyte concentration in the sample is greater than four times the spike level. The associated blank spike was acceptable.

ANALYTICAL REPORT

October 29, 2021

PDC Laboratory, Inc.

Sample Delivery Group:	L1416552
Samples Received:	10/12/2021
Project Number:	EJ00598
Description:	

Report To: Gail Schindler
2231 W. Altorfer Drive
Peoria, IL 61615

Entire Report Reviewed By:

Mark W. Beasley
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All radiochemical sample results for solids are reported on a dry weight basis with the exception of tritium, carbon-14 and radon, unless wet weight was requested by the client. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

Mark W. Beasley
Project Manager

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDA	Minimum Detectable Activity.
Rec.	Recovery.
RER	Replicate Error Ratio.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(T)	Tracer - A radioisotope of known concentration added to a solution of chemically equivalent radioisotopes at a known concentration to assist in monitoring the yield of the chemical separation.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C1	Tracer recovery limits have been exceeded; values are outside upper control limits.
J	The identification of the analyte is acceptable; the reported value is an estimate.
U	Below Detectable Limits: Indicates that the analyte was not detected.

MEMORANDUM

DATE November 19, 2021 **Project No.** 21454831

TO Project File
Golder Associates

CC Jeff Ingram

FROM Annie Muehlfarth **EMAIL AMuehlfarth@golder.com**

DATA VALIDATION SUMMARY, VISTRA MNA – NEWTON, SURFACE WATER SAMPLING, DATA PACKAGE EJ00598, INORGANIC

The following is a summary of instances where quality control criteria in the functional guidelines were not met and data qualification was required:

- When a compound was detected in a blank (i.e. method, field), and the blank comparison criterion was not met, associated sample results were qualified as estimates (J) or non-detects (U).
- When duplicate criterion was not met, the associated sample result was qualified as an estimate (J for detects, UJ for non-detects).
- When matrix spike/matrix spike duplicate (MS/MSD) criterion was not met, the associated sample result was qualified as an estimate (J for detects, UJ for non-detects).
- When a compound was detected in a sample result between the MDL and the PQL the results were recorded at the detection value and qualified as estimates (J).

Comments/Notes:

Dilutions: Sulfate, Ferric Iron, Soluble Metals (excluding lithium), and Total Metals (excluding lithium) were analyzed at a dilution in multiple samples. No qualification was required.

Blanks:

B145055-BLK1: Alkalinity (2.50), associated with samples -01, -02, -05 through -09, -12 through -15, -17, -18, -20, 25, 27, and -30.

Sample results greater than 10x blank result, no qualification necessary.

B145143-BLK1: Alkalinity (2.50), associated with samples -03, -04, -10, -11, -16, -19, -22, -23, -24, -26, -29, -29.

Sample results greater than 10x blank result, no qualification necessary.

QA LEVEL IV - INORGANIC DATA EVALUATION CHECKLIST

Comments/Notes:

B145145-BLK1: Alkalinity (2.50), associated with samples -03, -04, -10, -11, -16, -19, -22, -23, -24, -26, -29, -29. Sample results greater than 10x blank result, no qualification necessary.

(MB) R3723020-1: Radium-228 (0.549 +/- 0.219). Associated with samples L1416552-20 through -30. Sample results <10x blank were qualified as an estimate (J).

FB:

N-FB-1 @ N-E-1: Dissolved Sodium (0.12). Associated result is >RL and 10x blank, no qualification necessary.

DUP:

N-DUP-1 @ N-B-1: DUP RPD exceeded limit (20%) for Total Iron (27.0%); Total Nitrate Nitrogen and Radium-228 detected in DUP and non-detect in sample.

The lab analyzed sample duplicates for Radium, TDS,

B144564-DUP2: RPD limit (5%) exceeded by TDS (27%). Associated with sample -20

B144565-DUP1: RPD limit (5%) exceeded by TDS (14%). Associated with sample -22

B144565-DUP2: RPD limit (5%) exceeded by TDS (7%). Associated with sample -23

B145055-DUP1: RPD limit (10%) exceeded by Alkalinity (15%). Associated with sample -01

MS/MSD:

B144698-MS1/B144698-MSD1: MS/MSD % recovery unusable since analyte concentration in sample is >4x spike for Chloride and Sulfate, associated with sample -29. Qualified as an estimate.

B144698-MS2/B144698-MSD2: MS/MSD % recovery unusable since analyte concentration in sample is >4x spike for Chloride and Sulfate, associated with sample -30. Qualified as an estimate.

B145177-MS1/B145177-MSD1: % recovery low and RPD exceeds limit for Ferrous Iron, associated with sample N-F-1. Qualified as an estimate.

1. EXECUTIVE SUMMARY

This report documents the geochemical conceptual site model GCSM describing the conditions of the groundwater in the vicinity of Newton Power Plant (NPP) Primary Ash Pond (PAP). A GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. This report describes the GCSM for parameters that have exceeded the GWPS in PAP groundwater and which will be addressed in the corrective action plan. The exceedances observed at the PAP were sulfate, total dissolved solids (TDS), and lithium.

Groundwater was monitored in two hydrostratigraphic units: the shallow upper drift/potential migration pathway (UD/PMP) and the deeper uppermost aquifer (UA). The uppermost aquifer is shallowest (*i.e.*, in closest proximity to the upper drift/primary migration pathway) on the east side of the PAP. Groundwater in the UD/PMP and eastern UA wells tend to be geochemically similar: groundwater from these locations tends to be more oxidizing, exhibit lower pH, and have a cation signature dominated by calcium and magnesium. Groundwater in the rest of the UA tends to be more reducing (exhibiting higher dissolved iron concentrations), have higher pH, and have a greater contribution of sodium and potassium to the cation signature. These results suggest some degree of hydraulic connection between the UD/PMP and UA east of the PAP.

Sulfate is the major contributor to TDS in the PAP groundwater. Therefore, processes that control sulfate concentrations also control TDS. Elevated sulfate concentrations were observed in shallow groundwater wells (screened in the upper drift/primary migration pathway) and uppermost aquifer wells located east of the PMP. Sulfate in CCR porewater and the UD/PMP groundwater is correlated with sodium, indicating that dissolution of sodium sulfate from the CCR material is the primary source of sulfate to the CCR porewater. Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. Potential sulfate attenuation mechanisms at the NPP PAP include sorption to solid-phase iron oxides. Based on results from laboratory batch testing, sulfate sorption may be more likely in the UA.

Lithium concentrations in groundwater are highest in UD/PMP and eastern UA groundwater. Although lithium was identified in solid samples located both upgradient and downgradient of the PAP, the similar distributions of lithium and sulfate suggest that CCR porewater is the primary source of lithium to the groundwater. The difference in groundwater lithium concentrations may be due to variability in porewater concentration or in attenuation to aquifer solids. Lithium in groundwater may be attenuated by sorption to exchangeable sites (readily reversible) or incorporation in clay mineral matrices (poorly reversible). According to results from laboratory batch testing, lithium may sorb to both UA/PMP and UA solids.

2. INTRODUCTION

This report documents the GCSM describing the conditions of the groundwater in the vicinity of NPP PAP. This GCSM serves as an attachment to thee NPP PAP Nature and Extent Report (NPP PAP N&E Report) and describes the chemical processes that contribute to the mobilization, distribution, and potential attenuation mechanisms of parameters that exceed the GWPS in PAP groundwater (*i.e.*, the nature of the exceedance parameters). Exceedances in PAP monitoring network wells were submitted to the Illinois Environmental Protection Agency (IEPA) in accordance with Illinois Administrative Code (I.A.C) Title 35 § 845 (35 I.A.C. § 845) for the second, third, and fourth quarters of 2023 (Ramboll, 2023, 2024a, b).The exceedances observed at the PAP were sulfate and total dissolved solids (TDS) at monitoring wells APW02, APW04, APW05S, and APW10 and lithium at monitoring well APW02. Wells APW02, APW04, and APW05 are screened in the upper drift/potential migration pathway (UD/PMP) and well APW10 is screened in the uppermost aquifer (UA).

2.1 Site Overview

A detailed overview of the site history, geology, and hydrogeology is presented in (NPP PAP N&E Report). Briefly, the NPP is located in Jasper County in the southeastern part of central Illinois, approximately seven miles southwest of the town of Newton. The PAP is located south of the NPP and surrounded by Newton Lake to the south, east, and west (**Figure 2-1**). Beyond the lake is agricultural land. The PAP is an unlined coal combustion residual (CCR) surface impoundment constructed in 1977 and used to manage CCR and non-CCR waste streams at the NPP. The PAP is known to contain bottom ash and fly ash derived from Illinois (pre-1997) and Powder River Basin (post-1997) coals.

There are six hydrostratigraphic units in the vicinity of the PAP: CCR, the UD/PMP, the upper confining unit, the UA, the lower confining unit, and the bedrock unit (from shallowest to deepest). The UD/PMP is composed of low permeability clays and silts of the Peoria Silt and Sangamon Soil with discontinuous sand and sandy clay lenses of the Hagarstown Member. The UA is a continuous zone of moderate permeability comprising poorly graded sand, silty sand, clayey sand, and gravel of the Mulberry Grove Formation. The UA is shallowest east of the PAP and deeper west of the PAP. Background and compliance monitoring well locations (per the Groundwater Monitoring Plan for the PAP; Ramboll, 2021) and the fourth quarter 2023 (Q4 2023) UA groundwater contours are shown on **Figure 2-1**. Groundwater flow in the UA is generally north to south beneath the center of the PAP (from APW05/APW06 toward APW09/APW15). Beneath the western portion of the PAP, flow is west to southwest converging towards a former surface drainage feature located west of the PAP and an area where the uppermost aquifer is lowest in elevation and has the highest hydraulic conductivity. Beneath the eastern portion of the PAP groundwater flows east to southeast (from APW05 toward APW11-APW14). The groundwater elevation within the PAP is greater than the groundwater elevation in the UD/PMP, indicating that there may be radial flow away from the unit within the UD/PMP.

2.2 Constituent Transport and Fate

Sulfate is the primary form of oxidized sulfur (S(VI)) in the environment and is a divalent oxyanion at pH values greater than 2 SU (Stumm and Morgan 1996). Sulfate in groundwater may sorb onto positively charged sites on solid metal oxide phases, most commonly iron and manganese oxides (Brown et al., 1999). The extent and strength of sulfate sorption to metal

oxide surfaces depends on pH, ionic strength, and oxide surface area available for sorption. Sulfate can also form insoluble complexes such as barite (BaSO4) (Nation Center for Biotechnology Information (NCBI), n.d.). Sulfate in groundwater may be reduced to elemental sulfur (S(0)) or sulfide (S(-II)) under sufficiently reducing conditions, a process governed by local microbial communities(Stumm and Morgan, 1996). Generally, reduced sulfur is less mobile in groundwater than sulfate. Reduced sulfur readily precipitates as metal sulfides and sorbs to solid phases (such as iron and manganese oxides; Stumm and Morgan, 1996).

TDS represents the mass of dissolved material in the water rather than a specific chemical constituent. Individual constituent contributions to TDS depend on both the concentration and molar mass of each contributor. Typically, major ions (*i.e.*, calcium, sodium, magnesium, potassium, chloride, sulfate, and carbonate species) represent the primary contributors to TDS. Therefore, source and sink terms that affect the primary contributors to TDS, such as sulfate, will ultimately have the greatest effect on TDS concentrations.

Lithium is a monovalent cation in the same periodic table group as sodium and potassium but has a smaller ionic radius. Lithium can sorb to exchangeable sites on metal oxides and clay minerals (Steinhoefel et al., 2021) but tends to be displaced by other cations during ion exchange. However, lithium sorbed to clays may be incorporated deeper into the mineral matrix for more permanent immobilization, a process which drives lithium fractionation in the environment (Li and Liu, 2020; Steinhoefel et al., 2021).

3. SOLIDS CHARACTERIZATION

3.1 Methods

Attachment 1 details CCR and aquifer solid boring locations and collection methodology. Both CCR and aquifer solid borings were located adjacent to monitoring wells at depth corresponding to screened intervals. **Table 3-1** summarizes boring identifiers and collection depths per **Attachment 1**; adjacent groundwater monitoring well names, used in this section to refer to the solid phase samples for easier comparison with groundwater results; and methods of analysis. Aquifer solids collected adjacent to APW05 represent upgradient (*i.e.*, background) conditions in the UA. The UD and PMP are discussed together because they are screened at similar depths and only one sample location represents the PMP (APW05S). The UD/PMP does not have background samples due to the hydraulic gradients between the pond and the UD/PMP.

Bulk solids characterization included cation exchange capacity (CEC), loss on ignition (LOI), X-ray fluorescence (XRF), and total metals. The CEC of a solid phase represents the negative surface charge, and therefore the potential to sorb cations such as lithium. Clays and organic matter in aquifer materials typically carry a negative surface charge and therefore tend to enhance cation exchange capacity. LOI represents the combustible portion of a solid material and is often an approximation of organic matter in a sample. Therefore, it may be inferred that organic matter (as quantified by LOI) is a major contributor to CEC if CEC and LOI are directly correlated in solid phase materials. XRF analysis is a test that measures the fluorescent x-rays emitted from a solid sample excited by a primary x-ray source to quantify the relative proportions of major elements in a sample. Results from XRF analysis are reported as oxides due to the borate fusion preparation method used.

Sequential extraction procedure (SEP) is an analytical method that uses progressively stronger reagents to dissolve solid phase fractions and measures the metal content associated with each fraction. The natures of the solid-phase fractions are functionally defined by the reagents used in each dissolution step and should therefore not be considered definitive characterizations.

Metals in aquifer solids samples were analyzed by SEP by Eurofins in 2021 and by SGS in 2023. The two labs used different methods for the SEP analysis: Eurofins used a seven-step procedure while SGS used a six-step procedure (**Attachment 2** and **Attachment 3** respectively for details). The extractions performed for the two test methods generally target a similar set of soil fractions, though variations in extraction conditions and reagents (**Table 3-2**) may lead to differences in absolute values. It is therefore helpful to define nomenclature to discuss results based on the target fractions. In the Eurofins 2021 seven-step procedure, step three ("Non-Crystalline Materials") represents, in part, non-crystalline iron and manganese oxides, while step four ("Metal Hydroxides") encompasses more crystalline iron and manganese oxides. In the SGS 2023 six-step procedure, the iron and manganese oxides (implicitly both non-crystalline and crystalline) are represented by a single "Fe and Mn Oxides" fraction (step four). In the following discussion, "metal oxides" is used to describe Eurofins steps three and four and SGS step four results across analyses. In the Eurofins 2021 seven-step procedure, the most recalcitrant (*i.e.,* resistant to mobilization) fractions are extracted separately as "Acid/Sulfides" (step six, extracted by aqua regia) and "Residual" (step seven, extracted by mixed acids including HF), whereas in the SGS 2023 six-step procedure the "Residual" (step six, extracted by mixed acids including HF) fraction will encompass all of the recalcitrant material. Therefore, "recalcitrant" is used to

describe Eurofins steps six and seven and SGS step six results across analyses. Differences in results between the two methods may also be due to sample heterogeneity as different depths may have been analyzed for the same location and hydrostratigraphic unit (summarized in **Table 3-1**). The percent contribution of each fraction was calculated by summing the results of fractions one through seven (excluding non-detect values) and dividing each detected result by that sum.

Mineralogy was determined using x-ray diffraction (XRD), TESCAN integrated mineral analysis (TIMA), and electron microprobe analysis (EMPA) with laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS). Identifying mineral phases aids in understanding attenuation mechanisms and aquifer capacity. XRD quantifies the relative proportion of crystalline mineral phases by comparing the x-ray diffraction patterns observed in a sample to those of known compounds in a reference database. TIMA identifies mineral phases using a combination of energy dispersive X-ray silicon drift detectors and backscattered electron and secondary electron detectors. EMPA analyzes the chemical composition of selected minerals (in this case, clays and micas). LA-ICP-MA is combined with EMPA to determine the lithium content of the clays and micas characterized by EMPA.

3.2 CCR

The SEP results for lithium, iron, and manganese in CCR materials are shown in **Figure 3-1** and tabulated in **Table 3-3**. Iron and manganese oxides and hydroxides tend to coat soil particles and carry a surface charge that vary based on pH. Iron and manganese oxides and hydroxides therefore represent possible sorption sites for many ions, including lithium and sulfate. There is considerable heterogeneity in lithium, iron, and manganese concentrations and dominant SEP fractions between the two sampling locations.

Results of XRD characterization of CCR solids are summarized in **Table 3-4** (lab report in **Attachment 4**). The material from XPW01 was primarily quartz with other major contributions from albite (a sodium-rich feldspar), microcline (a potassium-rich feldspar), and muscovite (a mica). In contrast, the material from XPW04 contained a lower proportion of quartz and had at least 8% contribution each from albite, calcite (calcium carbonate), diopside, perovskite, and gehlenite. Perovskite, gehlenite, and many of the trace (<5% abundance) minerals found in XPW04 (periclase, hematite, magnetite, mullite, and ganophyllite) were not detected in XPW01.

The SEP and XRD characterization of these two CCR samples suggest considerable variability in the chemical composition of the CCR stored in the PAP. Additionally, the differences in SEP fractions and minerals suggest differences in chemical mobility between the two samples. The ash composition and the local geochemical environment will control porewater composition within the unit.

3.3 Aquifer Solids

3.3.1 Bulk Characterization

Figure 3-2 shows the CEC and LOI results for solid samples from the aquifer solids. The UD and PMP samples typically had a higher CEC and lower LOI (suggesting lower organic content) relative to the UA samples. This suggests that the greater CEC of the UD and PMP samples is not related to greater organic matter content and may instead be due to clay mineral components.

3.3.2 Metals

Figure 3-3 shows the concentrations of iron, manganese, and lithium in each SEP fraction as well as the proportion each fraction represents out of the summed SEP results for samples analyzed in 2021 (**Figure 3-3a**) and 2023 (**Figure 3-3b**) (results tabulated in **Table 3-3**). Summed iron in the 2021 UD/PMP results was lowest in APW05S and highest in APW02. In 2023 analyses, summed SEP iron was lowest in APW05S and highest in APW04. APW05S may have the lowest concentrations of iron due to a smaller surface area of sandier PMP material. In both analyses, over 50% of the total iron was in the recalcitrant fractions followed by presence in the metal oxide fractions. The 2021 results indicate that in the UD/PMP, iron was not abundant in the non-crystalline material (<3% of iron). Summed SEP iron concentrations in the UA were similar to UD/PMP concentrations, and downgradient concentrations were not consistently different from the background location. Similar to in the UD/PMP, iron in UA samples in both the 2021 and 2023 analyses was most abundant in the recalcitrant fractions followed by the metal oxide fractions. Results from the 2021 samples indicate that iron in UA samples is present in more equal proportion between the non-crystalline material and metal hydroxide fractions in the UA relative to the UD/PMP. The exception to this is the sample from APW10, which has a distribution more similar to UD/PMP wells. Non-crystalline iron hydroxides tend to have a greater capacity to sorb ions compared to more crystalline phases (Trivedi & Axe, 2001). These results suggest that despite similar concentrations of iron in the combined non-crystalline material and metal hydroxide fractions in the UD/PMP and UA, solid-phase iron in many UA locations may have greater capacity for sorbing ions.

Summed SEP manganese concentrations in the UD/PMP were lowest in APW05S and highest in APW04 in both 2021 and 2023 results. Similar to iron, APW05S may have the lowest concentrations of manganese due to a smaller surface area of sandier PMP material. Summed SEP manganese concentrations at downgradient UA locations were not consistently different from the background location. The 2021 analysis of UD/PMP and UA samples shows manganese distributed throughout the carbonate, non-crystalline material, metal hydroxide, and recalcitrant fractions, whereas the 2023 analysis showed the majority of the manganese in the carbonate fraction in both UA and UD/PMP samples. The 2021 analysis shows that the proportion of manganese in the non-crystalline material in UA samples tended to be lower relative to the UD/PMP, potentially indicating greater manganese oxide crystallinity in the UA compared to the UD/PMP. These results indicate that manganese is predominantly in reactive, rather than recalcitrant, in UD/PMP and UA aquifer solids.

Summed SEP results for lithium are slightly higher in the UD/PMP relative to the UA in both 2021 and 2023 analyses. Summed SEP lithium concentrations at UA compliance locations were not consistently different from the background location. Results from 2021 SEP analysis indicate that lithium is predominantly in the recalcitrant fractions and organic fraction with a small proportion in the metal hydroxide fraction in both the UD/PMP and UA. Results from 2023 suggest that lithium is predominantly in the recalcitrant fractions with a some in the Fe Mn oxide fraction and even less in the organic, carbonate, and exchangeable fractions in both UD/PMP and UA samples. This discrepancy in organic phase results may be due to the difference in reagents used (see **Section 3.1**). The higher lithium concentrations in the UD/PMP relative to the UA are largely due to a higher concentration measured in the recalcitrant fractions.

In general, these results indicate that lithium is strongly associated with recalcitrant solid-phase fractions (rather than weakly bound in the water soluble or exchangeable fractions). The

presence of lithium in the recalcitrant fraction of the background location indicates some naturally occurring lithium within the aquifer. However, aqueous lithium in groundwater may contribute to the lithium found in the metal oxide fractions by co-precipitation or sorption and/or to the recalcitrant fractions by sorption to clays and incorporation into the clay matrix (Steinhoefel, et al., 2021).

Aquifer solid contents were also analyzed by X-ray fluorescence (XRF) (**Attachment 5**). XRF analyses determine the percent by weight of individual elements (reported as their oxides due to the analytical method) based on their electron properties. Unlike in XRD, the XRF results are not normalized to 100%, so some proportion of the mass remains uncharacterized. **Figure 3-4** shows XRF results for the 2023 solids samples (the 2021 samples were not analyzed by XRF; **Table 3-1**). The dominant element in the XRF analysis was silicon, a major component of quartz (omitted from **Figure 3-4** due to scale). The next most prevalent species was aluminum, the other major component of aluminosilicate minerals. Calcium and magnesium, the central species in many carbonate minerals, were also abundant in all samples with the exception of APW05S. Iron was also relatively abundant in the XRF analysis, consistent with SEP results.

3.3.3 Mineralogical Analysis

The mineralogical composition of UD/PMP and UA solid phase samples was characterized by XRD (**Attachment 4**) and TESCAN integrated mineral analysis (TIMA) (**Attachment 6**). **Figure 3-5** shows the XRD results for the 2021 and 2023 samples (tabulated with mineral formulas in **Table 3-4**). XRD results are normalized to 100% of the total weight, meaning that material not characterized by XRD is ignored in the percent calculation. The dominant crystalline mineral contributor to solids in the UD and UA is quartz, which is omitted from **Figure 3-5** due to scale. In most samples, the next most abundant mineral phases were the carbonate minerals dolomite ($CaMg(CO_3)_2$) and calcite ($CaCO_3$). This finding is consistent with the abundance of manganese associated with the carbonate fraction in the SEP analysis. The one notable exception to the general abundance of carbonate minerals is the 2023 sample of APW05S, which had minimal carbonate minerals detected in the 2023 sample. This is consistent with the low contributions of calcium and magnesium in the XRF results measured on a sample from the same depth range, 10 to 16.6 feet below ground surface (ft bgs). In contrast, the 2021 XRD analysis for APW05S (collected from 18-20 ft bgs; **Table 3-1**) showed more abundant carbonate minerals. This difference in results at APW-05S indicates variability in aquifer solid composition within the PMP at this location. Muscovite, a phyllosilicate clay mineral, is more prevalent in most UD/PMP samples relative to UA samples. Other mineral phases detected include tectosilicate minerals (albite, orthoclase, and microcline); other phyllosilicate minerals (biotite and chlorite); inosilicate minerals (diopside and actinolite); ankerite (a carbonate mineral with varying proportions of calcium, magnesium, iron, and manganese as cations); and fluorapatite (a phosphate mineral). These minerals do not show substantial variability between UD/PMP and UA samples. Montmorillonite was detected only in the 2023 APW05S sample. The UA compliance samples did now show consistent variability relative to the background sample results.

Three UD/PMP samples were analyzed by TIMA (**Figure 3-5**). These samples represented the same depth ranges as those analyzed by XRD in 2023 (**Table 3-1**). The dominant mineral phase in all samples was quartz (omitted from **Figure 3-5** due to scale). Mixed clays/micas represented the next most abundant phase at APW04 and APW05S and had notably lower contributions to APW02. Plagioclase minerals (the mineral family to which albite, which was identified in XRD analysis, belongs) were prevalent in all three samples. Calcite and dolomite were also prevalent

phases samples from APW02 and APW04 but not in APW05S, consistent with the 2023 XRD results for carbonate minerals.

Figure 3-6 shows the results of the EMPA and LA-ICP-MS analysis. Data for EMPA is reported as a mass percent for the simple oxide of each element (**Attachment 7**). For Figure 3-6, mass percent was converted to the moles of each element and the mole fraction was obtained by normalizing to total moles of all elements. Using mole fraction rather than mass percent allows for a direct comparison of the abundance of each element independent of their weight. EMPA analysis identified that the composition of mixed clays/micas is predominantly silicon and aluminum followed by either calcium (APW02) or iron (APW04 and APW05S) (**Figure 3-6**). Concentrations of lithium in mixed clays/micas were between 53.3 mg/kg and 93.3 mg/kg, which are higher than concentrations observed in the total soil analyzed by SEP. This suggests that lithium is at higher concentrations in mixed clays/micas than in other mineral phases.

4. AQUEOUS CHARACTERIZATION

The PAP porewater and groundwater data discussed in this section are summarized in **Table 4-1** and tabulated in full in **Attachment 8**. Over time, different parameters have been collected at different frequencies at various wells due to the regulatory history of the unit. Wells in this discussion are grouped by the hydrostratigraphic unit in which they are screened (CCR porewater, UA, or UD/PMP) and by their classification in the monitoring network (background [B] or compliance [C]). Background wells are only screened in the UA (APW05 and APW06); upgradient UD/PMP locations are not available due to the hydraulic gradients present around the unit (NPP PAP N&E Report). Porewater is evaluated as a mobile source endmember representing conditions within the unit since collection began in 2021 (**Table 4-1**).

4.1 Exceedance Parameters and CCR Tracers

Figure 4-1 shows boxplots of boron, sulfate, and lithium data collected since 2015 from porewater, background groundwater, and compliance groundwater. Boron and sulfate are commonly used CCR tracers, and sulfate and lithium are the exceedance parameters of interest at the PAP because TDS includes sulfate concentrations. Boron is higher in all CCR porewater wells relative to groundwater and is highest in XPW01. With the exception of UD well APW03, boron concentrations in compliance groundwater are within the range of background boron concentrations. Compliance wells with the highest sulfate concentrations are UD/PMP wells and UA wells located east of the PAP where the UA is closest to the ground surface (APW10, APW11, APW13, and APW14). These eastern UA wells represent the extent of elevated sulfate in the UA and are referred to as a group throughout this discussion. Sulfate concentrations at other UA wells were largely consistent with background. Lithium was highest in porewater location XPW01 and UD well APW02. Lithium concentrations were generally higher in the UD and in eastern UA wells compared to background and other UA compliance wells.

4.2 Redox/pH Summary

The reduction-oxidation (redox) potential and pH of water are major controls on the speciation of redox-active chemicals such as iron, manganese, and sulfate. The redox potential of a solution is often measured in the field as the oxidation-reduction potential (ORP). ORP measurements represent the average electrical potential of all chemical species an aqueous solution. Eh is the measure of redox potential based on the standard hydrogen electrode and is calculated by converting an ORP measurement using an equation appropriate to the type of electrode used in the ORP sensor (typically silver/silver chloride or calomel). All Eh values presented here were converted from ORP measurements based on the guidance[1] provided by the field meter manufacturer (Horiba).

Figure 4-2 summarizes all available[2] measurements of Eh and pH in boxplots. CCR porewater tends to have more reducing and more basic conditions relative to groundwater wells. Wells in the UD tend to have more oxidizing conditions relative to wells in the UA (including UA background) with the exception of APW10, which has the most oxidizing groundwater in the UA and is comparable to conditions in the UD/PMP. Other UA compliance wells have Eh potentials

[1] https://static.horiba.com/fileadmin/Horiba/Products/Process_and_Environmental/Water_Pollution/Instruction_Manuals/U-50/U-50_Manual.pdf
[2] Data from 2023 Q1 excluded due to a malfunctioning ORP meter.

consistent with background. Wells in the UD/PMP tend to have lower pH relative to UA wells, and UA compliance wells have pH values consistent with background locations.

4.2.1 Pourbaix Diagram

Pourbaix diagrams show the predicted speciation of a constituent across pH values and redox potentials at thermodynamic equilibrium. **Figure 4-3** shows the median of the three most recent groundwater samples (Q2, Q3, and Q4 of 2024) plotted on the Pourbaix diagrams for manganese and iron species. Iron and manganese oxides and hydroxides tend to coat soil particles and carry a surface charge that varies based on pH. Iron and manganese oxides and hydroxides therefore represent possible sorption sites for many ions, including lithium and sulfate. The median metal concentrations (below), groundwater temperature (17 degrees Celsius), and bicarbonate alkalinity concentration (504 mg/L) were used to generate the aqueous and mineral equilibrium phases present on the diagram. Using median results as inputs allows for an evaluation of the prevailing conditions in the groundwater; however, speciation predictions for individual sample points are approximate.

The median dissolved manganese concentration in groundwater (0.083 mg/L) was used in the manganese Pourbaix diagram (**Figure 4-3a**). Manganese oxides (represented by birnessite, a common manganese oxide in soils) are not expected to be stable at any of the Eh and pH values observed in the porewater and groundwater. At lower pH values, manganese is expected to exist as the reduced divalent cation (Mn^{++}). At higher pH values representative of background and UA groundwater conditions, samples plot closer to rhodochrosite ($MnCO_3$) stability. The pH at which rhodochrosite is expected to form depends on the alkalinity. In general, rhodochrosite is closer to saturation in UA samples relative to UD/PMP samples. Although rhodochrosite was not observed in the XRD or TIMA analysis, manganese was associated with the carbonate phase in the SEP analysis and reduced manganese may substitute as a cation in carbonate minerals.

The median dissolved iron concentration in groundwater (1.3 mg/L) was used in the iron Pourbaix diagram (**Figure 4-3b**). Crystalline iron oxide phases (hematite, magnetite, and goethite) are suppressed because these phases were not detected in XRD or TIMA samples. Amorphous solid-phase iron hydroxides ($Fe(OH)_3$(ppd)) are expected to be generally stable at UD/PMP locations and at UA well APW10. The pH and redox signatures of other UA groundwaters approaches the line of equilibrium between iron oxides, dissolved ferrous iron (Fe^{++}), and siderite. Although siderite was not observed in the XRD or TIMA analysis, ankerite with a composition of $CaFe(CO_3)_2$ was detected in XRD and a small amount of iron was associated with the carbonate phase in the SEP analysis. Therefore, a mixed cation carbonate phase may host iron. The position of the UA samples relatively close to the intersection of $Fe(OH)_3$(ppd), ferrous iron, and an iron carbonate suggest that equilibrium reactions between these phases may occur in the groundwater.

4.2.2 Manganese and Iron Concentrations

Figure 4-4 presents boxplots summarizing dissolved ferrous iron, dissolved iron, and dissolved manganese concentrations in groundwater and porewater. Aqueous manganese concentrations are lowest in the porewater, and the median concentration of manganese is higher in the UD/PMP than the UA. The highest UA manganese concentrations were in the eastern UA wells. Dissolved ferrous iron (measured on filtered samples in the field using a colorimetric kit with a range of 0 to 6 mg/L and photometer) and dissolved iron concentrations were highest in both background and downgradient UA samples. APW10 was a low outlier in dissolved iron concentrations in the UA,

which is consistent with the more oxidizing conditions at this well contributing to $Fe(OH)_3$ stability. The UD/PMP groundwater samples had the highest frequency of dissolved ferrous iron and dissolved total iron below the detection limits but had lower median and maximum concentration than in CCR porewater.

Median dissolved manganese and dissolved iron concentrations for each well are shown in **Figure 4-5** with respect to longitude (x axis) and depth below ground surface (y axis), with all wells projected onto the same plane. Dissolved manganese is higher in UD/PMP and shallow eastern UA wells, whereas dissolved iron concentrations are higher in UA wells (with the exception of APW10, which is a low outlier as discussed earlier) relative to UD/PMP wells. Dissolution of manganese-containing carbonate minerals due to lower pH may be the source of elevated manganese in UD/PMP and eastern UA wells. Based on the dissolved iron concentrations and the Pourbaix diagram (**Figure 4-3b**), conditions in the UD/PMP and APW10 groundwater are insufficiently reducing to cause substantial iron reduction, whereas the rest of the UA groundwater is more likely to be iron reducing.

4.3 Major Ion Distribution/Signature

The major ion signature of the porewater and groundwater can be visualized using a Piper diagram. A piper diagram of the three most recent sampling events for each sampling location is shown in **Figure 4-6**. Porewater is consistently characterized by a higher proportion (>65%) of monovalent cations (*i.e.*, Na^+ and K^+) relative to divalent cations (*i.e.*, Ca^{2+} and Mg^{2+}), with monovalent cation contributions at porewater locations XPW01 and XPW04 consistently greater than 95%. Porewater locations show considerable heterogeneity in anion composition by location. Porewater location XPW03 has a relatively even proportion of carbonate species (i.e., HCO_3^- and CO_3^{-2}) versus sulfate and chloride, while XPW04 has over 95% contribution from sulfate and chloride.

Background groundwater at the site has roughly equivalent proportions of monovalent and divalent cations and is dominated by carbonate species over sulfate and chloride. Groundwater in the UD/PMP has a predominantly divalent cation signature and a wide range of anion signatures (from 88% carbonate species at APW03 to 84% sulfate and chloride at APW02). Groundwater in the UA varies from a similar signature as background to having a more prevalent divalent cation signature similar to the UD/PMP, with APW10 representing this extreme in the UA wells.

4.4 Statistical Analyses Supporting Source/Sink Terms

4.4.1 Multivariate Analysis

Groundwater data is frequently defined by many chemical parameters and may therefore be described statistically as "multivariate". Principal components analysis (PCA) is a common multivariate statistical approach that simplifies multivariate data by combining those variables into a smaller number of new variables called principal components. This is possible because in multivariate data sets, there is often some correlation between variables. These correlations represent "redundant" information that may be mathematically removed by PCA. The principal components (PCs) represent linear combinations of the original data which maximize the variance between the samples, and which are uncorrelated with one another. The PCs explain some proportion of the variance in the data, with a robust PCA analysis usually explaining at least 50% of the variance in the first two PCs. PCA thereby allows patterns in the data to be more easily recognized and correlations between input variables to be assessed. The goal of this PCA was to

characterize chemical composition similarities and differences between porewater and groundwater.

The PCA analysis included samples collected since the beginning of 2021 through fourth quarter of 2023 to represent the most recent site conditions. Samples with a turbidity greater than 50 nephelometric turbidity units (NTU) were excluded from the analysis to mitigate the confounding influence of suspended solids. Geochemical parameters were excluded from PCA when greater than 50% of the measurements were either missing or below detectable limits. Individual samples were excluded for those samples missing greater than 50% of measured parameters. Any measurements that were below the reporting limit were assumed to be half the reporting limit. Results for pH were converted to milligrams per liter (mg/L) H^+ ion for consistency with other analytes. Any missing values were imputed (*i.e.,* interpolated based on the available data) using the nearest neighbor method. The final data set (**Attachment 9**) contained 2,352 parameter measurements (145 of which were imputed) from 147 individual groundwater samples at 22 wells in the vicinity of the PAP (four porewater wells, two background wells, and 16 compliance wells). All data were log transformed, scaled, and centered so that parameters with larger concentrations did not have disproportionate influence on the results.

The results of PCA can be understood by evaluating how parameters relate to one another and the relationships between individual samples and the PCs. A PCA biplot is used to show the relationship of parameters and individual samples with the first two PCs. In a PCA biplot, the axes represent the PCs, and arrows originating from the center represent the input parameters. The length of the arrows and alignment with the axes represent how strongly each input parameter contributes to the PCs, and the direction of the arrow along an axis represents the direction of the contribution (positive or negative). Each data point represents a sample plotted according to the PCs.

Figure 4-7 shows a biplot of the first two PCs with the percent of variance explained by each PC indicated in the axis label. Sulfate concentrations are shown in a log scale by point size. CCR porewater samples plot most negatively on PC 1 (the x axis) and mostly in the upper-left quadrant, indicating a correlation with boron and potassium. This is consistent with the elevated boron concentrations (**Figure 4-1**) and the dominance of monovalent cations shown by the Piper diagram (**Figure 4-6**). Groundwater tends to plot positively on PC1 and therefore tends to be more acidic and have higher contributions from divalent cations. UD and eastern UA groundwater tends to plot positively on PC2 (upper right quadrant), in the direction of higher sulfate concentrations. In contrast, background and other UA groundwater plot negatively on PC2 (lower right quadrant) in the direction of higher barium. The inverse relationship between sulfate and barium in the PCA are consistent with barite formation as a control on sulfate and barium concentrations. Manganese and calcium characterize the signature (*i.e.*, point in the direction) of UD groundwater, which is consistent with a mixed calcium manganese carbonate mineral contributing these elements to the groundwater.

The cyan outline (within upper right quadrant) is the 95% confidence ellipse (which encompasses the area where 95% of the sample points fall) for the UD/PMP locations with sulfate exceedances. The darker blue outline represents the 95% confidence ellipse for eastern UA groundwater samples. There is considerable overlap between 95% confidence ellipses for the UD/PMP locations with sulfate exceedances and the eastern UA samples, indicating that these groups of samples have similar chemical compositions. In contrast, background and other UA groundwater samples plot in a distinct group from the UD and eastern UA groundwater.

4.4.2 Correlation Analysis

Figure 4-9a shows a biplot of sodium and sulfate in porewater and UD/PMP groundwater (the hydrostratigraphic unit with the highest sulfate concentrations[3]) with the results of a least squares linear regression. Concentrations in this figure are presented in millimolar (mM) rather than in mg/L to understand potential reaction stoichiometry. The relationship between sulfate and sodium in porewater and UD/PMP samples is strong (coefficient of determination $R^2 = 0.77$) and statistically significant ($p < 0.001$). Sulfate in UD/PMP groundwater is correlated with sodium in a similar ratio as CCR porewater (**Figure 4-8a**). The consistent relationship between sodium and sulfate in the porewater and UD/PMP groundwater suggests a similar source of both elements. In the porewater wells XPW01 and XPW04, which have distinctly elevated sulfate and sodium concentrations, the R^2 is even stronger at 0.89 and the slope of this regression is 0.49 (**Figure 4-8b**). This slope indicating that each atom of sulfate is associated with approximately two atoms of sodium.

One potential attenuation sulfate attenuation mechanism in groundwater is precipitation as barite (**Section 2.2**). **Figure 4-9** show a biplot of barium and sulfate in PAP groundwater. Concentrations in this figure are presented in millimolar (mM) rather than in mg/L to understand potential reaction stoichiometry. Concentrations of lower sulfate correspond to higher barium concentrations in the most of UA wells, indicating that barite may affect concentrations of sulfate and barium in the deeper groundwater. However, the molar concentrations of barium are generally much lower than sulfate, indicating a limited capacity for barite formation to remove sulfate from groundwater.

[3] Sulfate and sodium concentrations in UA wells do not show sufficient variability to contribute to this analysis.

5. LABORATORY TEST RESULTS

In 2021, aquifer solids and groundwater samples were submitted by Golder WSP to SiREM laboratory to test sorption and desorption behavior of sulfate and lithium using batch testing. Batch test studies combine soil and groundwater collected from a site of interest to evaluate the sorption and desorption of chemical constituents (**Attachment 10**).

5.1 Adsorption Batch Tests

For the adsorption tests, soil from APW05 (60.0 to 67.1 ft bgs) was paired with groundwater from well APW-04, representing sorption to UA soils. Soil from APW04 (12 to 18 ft bgs) was paired with groundwater from APW-14, representing sorption to UD/PMP soils. Groundwater was spiked to known concentrations of lithium and sulfate before being combined with soil in soil:water ratios ranging from 2:1 to 1:20. Control samples using only groundwater were also prepared. Samples and controls were prepared under an anoxic atmosphere and incubated in the dark under anoxic conditions at room temperature for 7 days. At the end of the test, concentrations of lithium and sulfate in the water were analyzed. The total amount of lithium and sulfate in the water versus in the solids of each sample were plotted according to three sorption models: linear, Langmuir, and Freundlich (for additional details about these sorption models, see **Attachment 10**). The fit of each sorption model to the data was evaluated using the coefficient of determination (R^2).

The sulfate sorption data for the UD/PMP did not exhibit good fit for any sorption model (see **Attachment 10** for full results). The sulfate data for the UA showed a linear relationship and had a linear sorption coefficient (K_d) of 3.58 L/kg (**Figure 5-1**). These results suggest the potential for some sulfate sorption in the UA, but do not support sorption in the UD/PMP.

The lithium sorption data for both the UD/PMP and UA samples were strongly consistent with the Langmuir sorption model (**Figure 5-1**). The Langmuir sorption coefficients (K_L) were 1.2×10^9 L/kg for the UD/PMP solid sample and 4.2×10^8 L/kg for the UA solid sample. These results suggest the potential for lithium sorption in both the UD/PMP and UA, with somewhat greater sorption in the UA indicated by the higher K_L.

5.2 Desorption Batch Tests

For the desorption tests, APW-05 groundwater (representing UA background) was paired with soil from APW02 (N-SB-02 at 12.5 to 20 ft bgs; UD/PMP) and from APW07 (N-SB-07 at 65 to 71.5 ft bgs; UA) at a 1:10 soil:water ratio. Samples were prepared under an anoxic atmosphere. Three sets of samples were prepared in duplicate and incubated either under ambient conditions, with oxygen sparging (representing oxic groundwater conditions), or with hydrogen sparging (representing anoxic groundwater conditions). Samples were incubated at room temperature for 7 days. The ambient control pH and ORP values on day 7 were more similar to results from hydrogen sparged samples than oxygen sparged samples (**Figure 5-2**).

Desorption of sulfate and lithium from the UD/PMP sample was observed under all redox conditions (**Figure 5-3**). There were no substantial differences in desorption under different redox conditions, which may be due to the variability between duplicates. These results suggest that sulfate and lithium are sorbed to UD/PMP solids and that sorption is to some extent reversible under background groundwater conditions. No sulfate or lithium sorption was observed

from the UA sample under any redox condition (with the exception of lithium in one oxygen-sparged duplicate sample; **Figure 5-3**). This may indicate little sorption of sulfate and lithium to UA solids and/or that existing sorption is not reversible under background groundwater conditions.

6. GEOCHEMICAL CONCEPTUAL SITE MODEL

6.1 Source and Distribution of Sulfate and TDS

Following evaluation of the solids and aqueous geochemical data collected, the primary source of sulfate to the UD/PMP is the CCR porewater. No minerals were identified in aquifer material that would contribute sulfate to groundwater. Heterogeneity in UD/PMP sulfate concentrations may be due to differences in porewater contribution or differences in local porewater contributions.

Sulfates in CCR material are commonly created during desulfurization processes. Commonly, materials such as calcium oxide, calcium carbonates, or sodium carbonates are used. The process by which these materials remove sulfate from flue gas is the formation of solid phase sulfates (*e.g.*, $CaSO_4$ and Na_2SO_4). When sodium carbonates are used as the desulfurization material, other sodium salts (residual sodium chemicals) may also be present in the waste material as combustion by-products (Raclavska et al., 2010; Kalisz et al., 2023). The use of sodium bicarbonates and the presence of residual sodium chemicals in fly ash may drive a higher leaching potential of TDS, sulfates, and metals (Raclavska et al., 2010; Kalisz et al., 2023). The molar ratio between sulfate and sodium in high-sulfate porewater (*i.e.*, from XPW01 and XPW04) is consistent with sodium sulfate dissolution (**Figure 4-9b**), suggesting that the dissolution of sodium sulfates in CCR material within the PAP is the primary driver of high sulfate concentrations in the porewater. The heterogeneity of sodium and sulfate concentrations in the PAP porewater suggests sporadic placement within the PAP of CCR produced when sodium carbonate injection was used in desulfurization processes at the NPP from 1979 to 1996.

Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. The UA is shallower on the eastern side of the PAP, putting the UD/PMP and UA in closer proximity (NPP PMP N&E Report, Figure 2-8). Water in the UD/PMP and eastern UA wells is similar in redox chemistry (**Section 4.2**) and geochemical signature (**Section 4.3** and **Section 4.4.1**), suggesting communication between the UD/PMP and UA in this area.

6.2 Source and Distribution of Lithium

Both naturally occurring soil and CCR porewater sources of lithium were identified (**Section 3.3** and **Section 4.1**). The bedrock underlying the site is shale (NPP PAP N&E Report). Lithium is naturally occurring in shale bedrock and overlying regolith and is released to groundwater during weathering processes (Steinhoefel et al., 2021). SEP analysis indicates lithium in recalcitrant aquifer solid fractions which is consistent with soil native lithium. However, lithium is higher in wells with elevated sulfate concentrations, suggesting a similar source as sulfate (**Figure 4-1**). Additionally, lithium concentrations are not elevated in background wells. It is therefore likely that the PAP is the source of most of the lithium contributing the GWPS exceedance.

6.3 Potential Attenuation Mechanisms

The primary mechanisms of sulfate in the environment are reduction to sulfide followed by mineral precipitation, sorption to positively charged sites on iron oxides, and precipitation as insoluble sulfate minerals (**Section 3.3**). Given the observed redox chemistry of the PAP groundwater, reduction of sulfate to sulfide is unlikely. Concentrations of barium in the groundwater are substantially lower than those of sulfate, suggesting limited capacity for barite precipitation to attenuate sulfate. The presence of iron oxides in the aquifer solids is indicated by

SEP results. Iron oxides may not have appeared in the XRD results due to poor crystallinity. Amorphous (*i.e.*, poorly crystalline) iron oxides tend to provide greater capacity for ion sorption (Trivedi and Axe, 2001). The surface charge on iron oxides is related to groundwater pH, with the surface carrying a more positive charge at more acidic pH values (Stumm and Morgan, 1996). The circumneutral to slightly acidic pH of the UD/PMP and the presence of iron oxides are therefore conducive to sulfate sorption and attenuation. However, the batch test results indicate that the capacity of UD/PMP solid phase materials to sorb sulfate may be saturated.

Lithium in groundwater may be attenuated by sorption to exchangeable sites or incorporation in clay mineral matrices. Lithium is readily displaced by exchangeable sites by other cations which are abundant in the PAP groundwater. However, some proportion of lithium may sorb to clay minerals, particularly aluminum hydroxides, and subsequently become incorporated into the mineral matrix with poor reaction reversibility (Pistiner and Henderson, 2003; Prodromou, 2016). TIMA results identified micas/clays as an abundant solid phase (>20%) at APW04 and APW05S, supported by the identification of clays in boring logs (NPP PAP N&E Report). The abundance of clays/micas was lower in APW02 (<10%) where aqueous lithium concentrations are highest. These results suggest that sequestration to clay minerals may provide a sink for lithium in the UD/PMP.

Notes:
CEC = cation exchange capacity
ft bgs = feet below ground surface
LOI = loss on ignition
SEP = sequential extraction procedure
TIMA = TESCAN integrated mineral analysis
XRD = X-ray diffraction
XRF = X-ray fluorescence

Table 3-2. Summary of Sequential Extraction Procedures
Geochemical Conceptual Site Model
Newton Primary Ash Pond
Newton Power Plant
Newton, IL

SEP Step	SEP Fraction	Extractant
		Seven Step Extraction (Eurofins, 2021)
Step 1	Exchangeable	1 M magnesium sulfate
Step 2	Carbonates	1 M sodium acetate/acetic acid at pH 5
Step 3	Non-Crystalline Materials	0.2 M ammonium oxalate at pH 3
Step 4	Metal Hydroxides	1 M hydroxylamine hydrochloride in 25% acetic acid
Step 5	Organics	5% sodium hypochlorite at pH 9.5
Step 6	Acid/Sulfides	3:1:2 v/v HCl:HNO_3:H_2O
Step 7	Residual	HF, HNO_3, HCl, H_3BO_3
		Six Step Extraction (SGS, 2023)
Step 1	Water Soluble	Nanopure water
Step 2	Exchangeable	1 M magnesium chloride
Step 3	Carbonates	1 M sodium acetate/acetic acid at pH 5
Step 4	Fe and Mn Oxides	0.04 M hydroxylamine hydrochloride in 25% acetic acid
Step 5	Organics	3:5:5 v/v 0.02 M HNO_3:30%H_2O_2:1.2 M ammonium acetate in 20% HNO_3
Step 6	Residual	HF, HNO_3, HCl, $HClO_4$

Notes:
M = molar
v/v = volume ratio

TECHNICAL MEMORANDUM

DATE December 15, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company (IPGC)

CC Brian Hennings - Ramboll

FROM Pat Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

MONITORED NATURAL ATTENUATION FIELD INVESTIGATION STATUS UPDATE, PRIMARY ASH POND (CCR UNIT 501) NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

The following Technical Memorandum summarizes the results received to date from the Monitored Natural Attenuation (MNA) Field Investigation completed by Golder Associates USA Inc. (Golder) for the Primary Ash Pond (PAP, CCR Unit 501) located at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. Data collected as a part of this investigation will be an integral part of the MNA Feasibility Demonstration for the PAP and will be used for IPGC's Illinois Part 845 Coal Combustion Residual (CCR) compliance program. A Site plan showing the PAP, existing Part 845 monitoring wells, and the MNA boring locations is provided in **Figure 1**.

This memorandum only includes laboratory analytical data that has been received to date. Golder will update this memorandum when the remaining data has been received and reviewed.

2.0 PROJECT SCOPE OF WORK

As part of the MNA Feasibility Demonstration, and ongoing discussions with IPGC, Golder completed the following activities as part of this Field Investigation:

- Screened for potential underground utilities in the vicinity of the proposed borings prior to completing any drilling or ground disturbance activities.
- Advanced a total of seven (7) soil borings ranging in depth from 15 to 90 feet below ground surface (ft bgs).
- Collected ten (10) soil samples from seven (7) soil borings for laboratory analysis.
- Collected groundwater samples from five (5) existing monitoring wells for laboratory analysis.

3.0 FIELD INVESTIGAITON

3.1 Private Utility Locate

Prior to conducting any work onsite, Golder reviewed Site plans/drawings provided by IPGC and/or Site representatives and met with Site representatives to assist in identifying underground utility locations in the vicinity

Golder Associates Inc.
13515 Barrett Parkway Drive, Suite 260, Ballwin, Missouri, USA 63021 T: +1 314 984-8800 F: +1 314 984-8770

of the proposed borings. Golder also sub-contracted with GPRS to provide ground penetrating radar (GPR) and electromagnetic (EM) tracing services to screen the proposed boring locations in the field. All boring locations were cleared by GPRS personnel before drilling commenced.

3.2 Drilling and Aquifer Solids Sampling

Drilling was completed by Cascade Environmental Drilling (Cascade) using a roto-sonic drill rig under direct supervision of a Golder Geologist from August 17 – 21, 2021. Continuous soil core samples were obtained at each borehole location and were logged in the field by Golder personnel. Soils were classified according to the Unified Soil Classification System (USCS) and in accordance with the standard Golder Soil Logging Technical Procedure.

During the field investigation, seven (7) soil borings were advanced at the locations shown on **Figure 1**. Soil boring logs are provided in **Attachment A**. The following units were encountered during the field investigation (unit names are consistent with the Groundwater Monitoring Plan (Ramboll, 2021) in the Newton Part 845 Operating Permit):

- Shallow Saturated Zone – This zone is made up of the Upper Drift and the Upper Confining Units. The Upper Drift consists of low permeability silts and clays of the Peoria Silt and Sangamon Soil and the Hagarstown Member (Potential Migration Pathway) which consists of discontinuous sandier deposits. Below the Upper Drift is the Upper Confining unit, which consists of low permeability clay and silt of the Vandalia Till. The contact between the Upper Confining Unit and the underlying Uppermost aquifer ranges from approximately 467 feet above mean sea level (FT MSL) to 483 FT MSL in the borings completed for this investigation. Samples from the shallow saturated zone are shown in **Table 1**.
- Uppermost Aquifer – This zone consists of the Mulberry Grove Formation and is generally made up of fine to coarse, poorly to well graded sands, with occasional clayey sand layers and gravels. The formation is present between approximately 449 and 483 FT MSL. Samples collected from the uppermost aquifer are shown in **Table 1**.
- Lower Confining Unit – This unit consists of the Smithboro Till and is generally made up of compact glacial till consisting of low permeability silty clays and clayey silts with trace sand and gravel. The Till was present directly below the Uppermost Aquifer and the contact between these two units ranges from approximately 449 FT MSL to 474 FT MSL. Drilling was terminated in the Lower Confining Unit in most boreholes, therefore, evaluation of the full thickness of the unit was not completed as a part of this investigation. There were no samples collected from the lower confining unit.

Methane was encountered in soil boring SB-02, on August 18, 2021, while retrieving the soil from 60 to 80 feet below ground surface (FT BGS) within the bottom of the Shallow Saturated Zone and the top of the Uppermost Aquifer unit. Drilling was stopped until methane levels dropped below safe working levels and continued on August 19, 2021. Methane was only detected in this borehole during this investigation.

Ten (10) soil samples were collected for laboratory analysis from the soil borings (see **Figure 1** for sample location). Details regarding collected samples are included in **Table 1**.

Table 1: Laboratory Soil Sample Locations and Intervals Used for Laboratory Analysis

Borehole ID	Sample ID	Sample Depth (FT BGS)	Soil Type / Geologic Unit Sampled
N-SB-02	N-SB-02 (12.5 – 20.0)	12.5 - 20.0	Clayey Silt / Shallow Saturated Zone
	N-SB-02 (65.0 – 71.5)	65.0 – 71.5	Well Graded Sand /Uppermost Aquifer
N-SB-04	N-SB-04 (12.0 – 18.0)	12.0 – 18.0	Sandy Silty Clay / Shallow Saturated Zone
	N-SB-04 (38.8 – 45.4)	38.8 – 45.4	Clayey Sand / Uppermost Aquifer
N-SB-05	N-SB-05 (18.0 – 20.0)	18.0 – 20.0	Poorly Graded Sand / Shallow Saturated Zone
	N-SB-05 (60.0 – 67.1)	60.0 – 67.1	Poorly Graded Sand / Uppermost Aquifer
N-SB-14	N-SB-14 (44.2 – 52.0)	44.2 – 52.0	Sandy Clay / Uppermost Aquifer
N-SB-18	N-SB-18 (77.5 – 80.0)	77.5 – 80.0	Well Graded Sand / Uppermost Aquifer
N-SB-XPW01	N-SB-XPW01 (10.0 – 12.7)	10.0 – 12.7	CCR
N-SB-XPW04	N-SB-XPW04 (10.0 – 15.0)	10.0 – 15.0	CCR

Notes

1) FT BGS – Feet Below Ground Surface.

3.2.1 Soil Laboratory Analysis

Soil samples collected during the field investigation were placed in clean containers and properly labeled with sample location, depth, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to the following laboratories for analysis:

- Eurofins TestAmerica for 7-Step Sequential Extraction; and
- SiREM for the Batch Testing, Total Metals, Reitveld X-Ray Diffraction (XRD), leachability, Cation Exchange Capacity (CEC), and Total Organic Carbon (TOC) analyses.

The following laboratory analyses were conducted for each soil sample:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld XRD Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

Currently, only the results from Test America have been received, and are included in **Attachment B**. A separate Technical Memorandum will be provided when results from SiREM are completed.

3.2.2 Borehole Survey

On September 1, 2021, IngenAE completed a survey of the boring locations including the longitude/latitude of and elevation of each borehole location. Survey information is included in the boring logs in **Appendix A**.

3.3 Groundwater Sampling

Groundwater sampling was completed by Golder personnel on August 31, 2021. Five (5) existing monitoring wells were sampled, provided in **Figure 1**. Groundwater sample locations and adjacent borehole sample intervals for the MNA evaluation are included in **Table 2**.

Table 2: Groundwater Sample Locations

Well ID	Adjacent Borehole Sample
APW-02	N-SB-02 (12.5 – 20.0)
APW-04	N-SB-04 (12.0 – 18.0)
APW-05S (background)	N-SB-05 (18.0 – 20.0)
APW-05 (background)	N-SB-05 (60.0 – 67.1)
APW-14	N-SB-14 (44.2 – 52.0)

3.3.1 Groundwater Sample Laboratory Analysis

Groundwater samples collected during the field investigation were placed in clean containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to SiREM Laboratories to be included in batch testing analysis along with soil samples collected at adjacent boreholes. Results for the batch testing has not yet been completed and will be provided in a separate Technical Memorandum.

4.0 CLOSING

Golder appreciates the opportunity to serve as your consultant on this project. If you have any questions concerning this technical memorandum or need additional information, please contact the undersigned

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Analysis Requested

140-24350 Chain of Custody

Preservation Codes:

A - HCL	M - Hexane
B - NaOH	N - None
C - Zn Acetate	O - AsNaO2
D - Nitric Acid	P - Na2O4S
E - NaHSO4	Q - Na2SO3
F - MeOH	R - Na2S2O3
G - Amchlor	S - H2SO4
H - Ascorbic Acid	T - TSP Dodecahydrate
I - Ice	U - Acetone
J - DI Water	V - MCAA
K - EDTA	W - pH 4-5
L - EDA	Z - other (specify)

Other:

Sample Identification	Sample Date	Sample Time	Sample Type (C=Comp, G=grab)	Matrix (W=water, S=solid, O=waste/oil, BT=Tissue, A=Air)	Field Filtered Sample (Yes or No)	Perform MS/MSD (Yes or No)	6010B - Select Total Metals	6010B_SEP - SEP	Total Number of containers	Special Instructions/Note:
			Preservation Code:				N	N		
N-SB-05(18.0-20.0)	8-17-21	1240	G	S	N	N	/	/		
N-SB-05(60.0-67.1)	8-17-21	1540	G	S			/	/		
N-SB-18 (77.5-80.0)	8-18-21	1000	G	S			/	/

Possible Hazard Identification
☐ Non-Hazard ☐ Flammable ☐ Skin Irritant ☐ Poison B ☐ Unknown ☐ Radiological

Sample Disposal (A fee may be assessed if samples are retained longer than 1 month)
☐ Return To Client ☑ Disposal By Lab ☐ Archive For _____ Months

Deliverable Requested: I, II, III, IV, Other (specify)

Custody Seals Intact: Δ Yes Δ No	Custody Seal No.:	Cooler Temperature(s) °C and Other Remarks:

Ver: 06/08/2021

EUROFINS/TESTAMERICA KNOXVILLE SAMPLE RECEIPT/CONDITION UPON RECEIPT ANOMALY CHECKLIST **Log In Number:** Loc: 140 **24350**

Review Items	Yes	No	NA	If No, what was the problem?
1. Are the shipping containers intact?	/			☐ Containers, Broken
2. Were ambient air containers received intact?			/	☐ Checked in lab
3. The coolers/containers custody seal if present, is it intact?	/			☐ Yes ☐ NA
4. Is the cooler temperature within limits? (> freezing temp. of water to 6 °C, VOST: 10°C) Thermometer ID : SC 71 Correction factor: +0.1	/			☐ Cooler Out of Temp, Client Contacted, Proceed/Cancel ☐ Cooler Out of Temp, Same Day Receipt
5. Were all of the sample containers received intact?	/			☐ Containers, Broken
6. Were samples received in appropriate containers?	/			☐ Containers, Improper; Client Contacted; Proceed/Cancel
7. Do sample container labels match COC? (IDs, Dates, Times)	/			☐ COC & Samples Do Not Match ☐ COC Incorrect/Incomplete ☐ COC Not Received
8. Were all of the samples listed on the COC received?	/			☐ Sample Received, Not on COC ☐ Sample on COC, Not Received
9. Is the date/time of sample collection noted?	/			☐ COC; No Date/Time; Client Contacted
10. Was the sampler identified on the COC?	/			☐ Sampler Not Listed on COC
11. Is the client and project name/# identified?	/			☐ COC Incorrect/Incomplete
12. Are tests/parameters listed for each sample?	/			☐ COC No tests on COC
13. Is the matrix of the samples noted?	/			☐ COC Incorrect/Incomplete
14. Was COC relinquished? (Signed/Dated/Timed)	/			☐ COC Incorrect/Incomplete
15. Were samples received within holding time?	/			☐ Holding Time - Receipt
16. Were samples received with correct chemical preservative (excluding Encore)?			/	☐ pH Adjusted, pH Included (See box 16A) ☐ Incorrect Preservative
17. Were VOA samples received without headspace?			/	☐ Headspace (VOA only)
18. Did you check for residual chlorine, if necessary? (e.g. 1613B, 1668) Chlorine test strip lot number:			/	☐ Residual Chlorine
19. For 1613B water samples is pH<9?			/	☐ If no, notify lab to adjust
20. For rad samples was sample activity info. Provided?			/	☐ Project missing info

ANALYSIS REPORT

Method Summaries *Test method information available upon request.*

S(T) and C(T): Total sulfur and total carbon by LECO, Method CSA06V
S(SO4): Sulfate by HCl digestion with ICP finish, Method CSA07V
S(S2-): Sulfide by calculation of S(T) - S(SO4)

TIC: Total inorganic carbon by coulometry, Method CSB02V
AP: Acid generating potential based on sulfide sulfur
NP: Modified neutralisation potential by excess acid addition and back titration to pH 8.3
Net NP: Net neutralisation potential = NP - AP
NPR: Neutralisation potential ratio = NP/AP

Metals by Aqua regia digest with ICP-OES/MS finish, Method ICP21B20/ICM21B20
Metals by multi-acid digest with ICP-OES/MS finish, Method ICP40Q12/IMS40Q12
Tessier Sequential Extraction - method available on request

SGS X-RAY DIFFRACTION LABORATORY REPORT

Quantitative X-Ray Diffraction by Rietveld Refinement

Report Prepared for:	*Environmental Services*
Project Number/ LIMS No.	*Custom XRD/MI4503-OCT21*
Sample Receipt:	*October 4, 2021*
Sample Analysis:	*October 8, 2021*
Reporting Date:	*November 2, 2021*

Instrument:	BRUKER AXS D8 Advance Diffractometer
Test Conditions:	Co radiation, 35 kV, 40 mA Regular Scanning: Step: 0.02°, Step time: 1s, 2θ range: 3-80°
Interpretations :	PDF2/PDF4 powder diffraction databases issued by the International Center for Diffraction Data (ICDD). DiffracPlus Eva and Topas software.
Detection Limit :	0.5-2%. Strongly dependent on crystallinity.

Contents:

ACCREDITATION: SGS Minerals Services Lakefield is accredited to the requirements of ISO/IEC 17025 for specific tests as listed on our scope of accreditation, including geochemical, mineralogical and trade mineral tests. To view a list of the accredited methods, please visit the following website and search SGS Canada - Minerals Services - Lakefield: http://palcan.scc.ca/SpecsSearch/GLSearchForm.do.

Method Summary

The Rietveld Method of Mineral Identification by XRD (ME-LR-MIN-MET-MN-D05) method used by SGS Minerals Services is accredited to the requirements of ISO/IEC 17025.

Mineral Identification and Interpretation:

Mineral identification and interpretation involves matching the diffraction pattern of an unknown material to patterns of single-phase reference materials. The reference patterns are compiled by the Joint Committee on Powder Diffraction Standards - International Center for Diffraction Data (JCPDS-ICDD) database and released on software as Powder Diffraction Files (PDF).

Interpretations do not reflect the presence of non-crystalline and/or amorphous compounds, except when internal standards have been added by request. Mineral proportions may be strongly influenced by crystallinity, crystal structure and preferred orientations. Mineral or compound identification and quantitative analysis results should be accompanied by supporting chemical assay data or other additional tests.

Quantitative Rietveld Analysis:

Quantitative Rietveld Analysis is performed by using Topas 4.2 (Bruker AXS), a graphics based profile analysis program built around a non-linear least squares fitting system, to determine the amount of different phases present in a multicomponent sample. Whole pattern analyses are predicated by the fact that the X-ray diffraction pattern is a total sum of both instrumental and specimen factors. Unlike other peak intensity-based methods, the Rietveld method uses a least squares approach to refine a theoretical line profile until it matches the obtained experimental patterns.

Rietveld refinement is completed with a set of minerals specifically identified for the sample. Zero values indicate that the mineral was included in the refinement calculations, but the calculated concentration was less than 0.05wt%. Minerals not identified by the analyst are not included in refinement calculations for specific samples and are indicated with a dash.

Re : TIMA Mineralogical Analysis of Soil Samples with supporting EMPA and LA-ICP-MS data focused on Lithium Determination.

This memo summarizes testwork completed by the mineralogy group at SGS Burnaby, BC, Canada, on five samples submitted by WSP. The objective of the testwork was to characterize the mineralogy of samples and determine if any minerals contain low levels of lithium (Li). The analysis was completed using a combination of TIMA-X (TESCAN Integrated Mineral Analyser), XRD analysis (X-Ray Diffraction), EMPA (Electron MicroProbe Analysis) and LA-ICP-MS (Laser Ablation Inductively Coupled Plasma Mass Spectrometry). The modal mineralogy and elemental compositions are reported.

The analysis indicated that the samples were primarily composed of quartz (37.7-61.9%), with the phase of interest being mixed clay/mica species (8.41-22.5%). Moderate abundance of plagioclase (8.12-11.1%) and minor amounts of K-feldspar. Carbonates of calcite and dolomite are present in abundance in two of the samples. The Li concentration within the mixed clay/mica ranged from 3.25 ppm to 502.9 ppm.

1. Sample Preparation

Five samples were provided for the project and submitted to SGS Mineralogy. The samples were received wet and were dried at 30 °C. Dry weight was taken and inventoried, and all information was entered into a Laboratory Information Management System (LIMS) with the assigned number MI7011-NOV22.

Head geochemical assay submission was done on a pulverized subsample. Assays conducted were major elements by Whole Rock Analysis (WRA), including chlorine (Cl) using fusion X-ray Fluorescence (XRF), total S by LECO and trace metals by multi-acid ICP-MS/OES for lithium (Li) and boron (B). A subsample of each sample was submitted for XRD analysis, and a further subsample was submitted to the SGS ARD department for 6-step Tessier Sequential Extraction, to include boron.

Three samples were selected for further mineralogy analysis by TIMA, with EMPA and LA-ICP-MS based on the clay/mica content and lithium values. These selected samples were (N-SB-04 (12-18), N-SB-02 (10-13), and N-SB-05 (10-16.6).

Each sample was de-agglomerated, stage-crushed to a P80 of 150 µm and micro-riffled to obtain a ~2-3 g subsample, which was used to prepare two polished sections per sample.

2. Tessier Leach

The summary of lithium results of the 6-step Tessier Leach test on all five samples. Measured and normalized are given below in Table 1 and Table 2, and the full elemental suite is shown in the results attached.

Table 1: Summary of the Lithium results from the 6-Step Tessier Leach Test

Element	Tessier Leach Step	Unit	N-SB-04 (12-18)	N-SB-04 (40-45)	N-SB-02 (10-13)	N-SB-05 (10-16.6)	N-SB-14 (50-52)

3. MINERALOGY

3.1. X-RAY DIFFRACTION ANALYSIS

The mineral identification and interpretation by XRD involved matching the diffraction pattern of an unknown material to patterns of single-phase reference materials. The reference patterns are compiled by the Joint Committee on Powder Diffraction Standards - International Center for Diffraction Data (JCPDS-ICDD) database and released on software as Powder Diffraction Files (PDF). Quantitative Rietveld analysis is performed by using Topas 4.2 (Bruker AXS).

Interpretations do not reflect the presence of non-crystalline and/or amorphous compounds. Mineral proportions may be strongly influenced by crystallinity, crystal structure and preferred orientations. Mineral or compound identification and quantitative analysis results should be accompanied by supporting chemical assay data and additional mineralogy. The primary mineral was quartz, with notable amounts of muscovite and montmorillonite.

Table 3: Summary of Rietveld Quantitative Analysis X-Ray Diffraction Results

Mineral/Compound	N-SB-04 (12-18) JAN7011-01 (wt %)	N-SB-04 (40-45) JAN7011-02 (wt %)	N-SB-02 (10-13) JAN7011-03 (wt %)	N-SB-05 (10-16.6) JAN7011-04 (wt %)	N-SB-14 (50-52) JAN7011-05 (wt %)

TOTAL	100	100	100	100	100

3.2. TIMA-X MINERALOGY (ALTERNATIVE AUTOMATED MINERALOGICAL ANALYSIS)

TIMA-X is an acronym for TESCAN Integrated Mineral Analyzer, and it is based on four Energy Dispersive X-ray (EDX) silicon drift detectors (SDD) attached to a TESCAN MIRA (field-emission gun – FEG) platform, which also includes a backscattered electron (BSE) and secondary electron (SE) detectors. The TIMA system utilizes both the EDX and BSE signals to identify minerals at each measurement point (or each homogenous segment of a grain, depending upon the analysis mode). It is optimized to deal with rapidly acquired low-count spectra. These EDX (and BSE) spectra (and BSE data) are compared to entries in a mineral library on a first-match principle to identify the mineral phase. The mineral library is based on theoretical mineral/phase composition or created by the user based on BSE, X-ray spectral windows counts and ratios.

High-Resolution Mapping (THRM), was the selected scan mode. The THRM collects a BSE signal and an X-ray spectrum at a set resolution (3 µm) to map the particles. It collects modal and textural information, such as liberation or exposure analysis of grains of interest.

Three samples were analyzed using TIMA-X for the project. The mineral abundances were determined and shown below in Table 4, with the data report attached. The mineral phase of interest would be mixed clays/micas. These were grouped due to the fine-grained and intergrown nature of the minerals. The abundance of mixed clays/micas ranged from 8.41 % to 22.5% and on average ~17.3%.

Table 4: Modal Mineralogy by TIMA-X (across three selected samples)

	Other	0.09	0.09	0.07
	Total	100.0	100.0	100.0

3.3. EMPA AND LA-ICP-MS

The polished sections for each sample were submitted for EMPA and LA-ICP-MS at the University of New Brunswick, Microscopy and Microanalysis Facility. Electron Microprobe Analysis (EMPA) with selected minerals of interest (clays and micas) were analyzed to quantify the chemical composition of the major and minor elements. It is well known that many minerals display compositional variations. Therefore, EPMA was necessary to determine the chemistry of the minerals and identify the minerals correctly. LA-ICP-MS was combined with the EPMA to determine the Li content in the clay-sized and mica minerals.

The EMPA data indicated that the lithium concentration across all three samples ranged from 3.25 ppm to 502.9 ppm and averaged at 70.5 ppm. Among the three samples, N-SB-04 (12.0-18.0) showed the highest average Li concentration of 93.3 ppm, followed by N-SB-02 (10-13) at 67.6 ppm and N-SB-05 (10-16.6) at 53.3 ppm.

4. Conclusion

Due to the trace lithium grades and the fine-grained nature of the micas present, gathering a high number of satisfactory elemental data points was challenging, with only 64 viable LA-ICP-MS points out of 126 points selected. The variability of lithium content of the clay/mica grains was notably large, along with mixed EMPA spectra. Only eight grains had a value greater than 100 ppm Li, although sample N-SB-04 (12.0-18.0) had one at 502.9 ppm at point g11. This sample contains muscovite, but due to the high Fe content, this high Li-bearing phase is suspected to be biotite (mica). Sample N-SB-05 (10-16.6) was the only sample to contain montmorillonite by XRD. That did not change the relative abundance of lithium within the samples compared to the muscovite-rich samples. To conclude, the LA-ICP-MS results, in conjunction with the TIMA data, indicated that the primary source of deleterious lithium was within the mixed clay/mica phases.

Refer to the official project report for extended TIMA, EMPA, and LA-ICP-MS data.

1. INTRODUCTION

Golder Associates, Inc. (Golder) retained SiREM to perform a laboratory treatability study to assess the adsorption and desorption behaviour of arsenic (As), boron (B), lithium (Li), and sulfate (SO_4^{2-}) in groundwater and geologic material from the Vistra Newton site in IL (the Site). The purpose of the study was to assess the sorption characteristics of As, B, Li, and SO_4^{2-} and generate site-specific sorption coefficients and further assess the stability of sorbed As, B, Li, and SO_4^{2-} under oxidizing, reducing, and alkaline conditions.

The geologic materials were collected by Golder personnel on 17-21 August 2021 and received by SiREM on 10 September 2021. The groundwater (APW-02, APW-04, APW-14, APW-05 and APW-05S) was collected by Golder personnel on 16 and 17 August 2021 and was received by SiREM on 23 August 2021. The groundwater samples were received outside of temperature at 19 degrees Celsius (°C). Therefore, the groundwater samples were re-collected on 31 August 2021 and received by SiREM on 2 September 2021 at 6 °C. The groundwater received on 2 September 2021 was the only groundwater used during the study. The materials received and chosen for the study are summarized in the Table below. The chain of custodies received with these samples are provided in Appendix A.

Test	Depth	Client ID (Sediment)	Client ID (Groundwater)
Adsorption	60.0'-67.1'	N-SB-05 (60.0'-67.1')	APW-04
	12.0'-18.0'	N-SB-04 (12.0'-18.0')	APW-14
Desorption	65.0'-71.5'	N-SB-02 (65.0'-71.5')	APW-05
	12.5'-20.0'	N-SB-02 (12.5'-20.0')	

The remainder of this report is divided into two sections. Section 2 presents the experimental materials and methods, and Section 3 presents the results.

2. MATERIALS AND METHODS

The following sections describe the materials and methods used for baseline sampling and homogenization (Section 2.1), adsorption test reactor construction and incubation (Section 2.2), desorption test reactor construction and incubation (Section 2.3), and study sampling and analysis (Section 2.4).

2.1 Baseline Sampling and Homogenization

2.1.1 Baseline Elemental and Mineralogy Sampling and Analysis

Site geologic material from all locations and depths were individually homogenized, and sub-sampled on 21 September 2021 for total metals and anions including As, B, Li, and SO_4^{2-}, total organic carbon (TOC), cation exchange capacity (CEC), X-ray diffraction (XRD), and loss on ignition (LOI) analyses, and on 1 March 2022 for synthetic precipitation leaching procedure (SPLP) for As, B, Li, and SO_4^{2-} (N-SB-XPW01 and N-SB-XPW04 only). Site groundwater was also sub-sampled on 21 September 2021 for analysis of dissolved metals and anions, dissolved organic carbon (DOC) and total dissolved solids (TDS).

Samples were collected in a temporary anaerobic glove bag filled with a 100 percent (%) nitrogen (N_2) headspace. After homogenization and sample collection the geologic material was removed from the anaerobic glove bag and stored at 4 ºC in N_2 purged polypropylene bags with minimized headspace until required for test set-up.

2.2 Adsorption Test Reactor Construction and Incubation

Adsorption test reactors were constructed in an anaerobic chamber (Coy Laboratory Products, Grass Lake, MI) filled with an atmosphere of approximately 80% N_2, 10% carbon dioxide (CO_2) and 10% hydrogen (H_2) (Linde Gases, Guelph, ON). H_2 in the anaerobic chamber functions to scavenge trace oxygen (O_2) via a palladium catalyst. Anaerobic conditions in the anaerobic chamber were verified using an indicator containing resazurin (Sigma, St. Louis, MO) in a mineral medium which turns pink in the presence of O_2. APW-04 groundwater and N-SB-05 (60.0'-67.1') geologic material was used to construct the first set of reactors. The second set of reactors were constructed using APW-14 groundwater with N-SB-04 (12.0'-18.0') geologic material. For both sets of reactors, geologic material was added on 14 February 2022 (Day -1) and the groundwater was spiked with As, B, Li, and SO_4^{2-} on 15 February 2022 (Day 0) and subsequently added to the reactors.

Reactors were constructed by filling sterile 125 milliliter (mL) (nominal volume), and 250 mL (nominal volume) Nalgene® bottles (Systems Plus, New Hamburg, ON) with a specified mass of geologic material and groundwater. The geologic material to groundwater (GM:GW) ratios tested in each set of reactors were 2:1, 1:1, 1:5, 1:10, and 1:20, based on the wet weight of the geologic material. Groundwater only controls were also constructed for each set.

In consultation with Golder, it was determined that the starting aqueous concentrations of As, B, Li, and SO_4^{2-} in the groundwater should be 200 micrograms per liter (µg/L), 10 milligrams per liter (mg/L), 300 µg/L, and 774 mg/L, respectively. The concentrations of all species were not at the target concentrations, therefore immediately before construction of the reactors, the entire volume of groundwater needed to construct each set of reactors was spiked with respective solutions prepared from the appropriate salt as detailed in the table below to target these concentrations in the aqueous phase of the reactors at the start of the adsorption test. Spiking occurred on 15 February 2022 (Day 0).

Compound	Target (mg/L)	Salt Used to Prepare Spiking Solution	Chemical Formula
Arsenic	0.2	Metaarsenite	$NaAsO_2$
Boron	10	Boric Acid	H_3BO_3
Lithium	0.3	Lithium Chloride	LiCl
Sulfate	774	Sodium Sulfate	Na_2SO_4

After construction, the reactors were incubated in the anaerobic chamber for a period of 7 days. During incubation the reactors were inverted once a day to increase the contact between the geologic material and groundwater. During quiescent incubation all reactors were covered to minimize photodegradation and incubated at 22 °C (room temperature). Table 1 details the

reactor construction, incubation, amendments, and sampling parameters of the adsorption test reactors.

2.3 Desorption Test Reactor Construction and Incubation

Desorption test reactors were constructed in an anaerobic chamber filled with an atmosphere of approximately 80% N_2, 10% CO_2 and 10% H_2 on 21 March 2022 (Day 0). The APW-05 groundwater and N-SB-02 (65.0'-71.5') geologic material was used to construct the first set of reactors. The second set of reactors was constructed using APW-05 groundwater with N-SB-02 (12.5'-20.0') geologic material.

Reactors were constructed by filling sterile 125 mL (nominal volume) Nalgene® bottles with a specified mass of geologic material and groundwater. Based on the adsorption test results, the GM:GW ratio (based on the wet weight of geologic material) was selected to be 1:10 in both sets of reactors.

After construction, all reactors were incubated for a period of 7 days. The control reactors for each set were tested under ambient conditions in the anaerobic glove chamber with no amendments throughout the incubation period. Treatment reactors for each set were tested under highly reducing and highly oxidizing conditions. These conditions were established in the reactors through daily amendments of either H_2 or O_2, respectively. The H_2 sparged reactors were kept in the anaerobic glove chamber throughout the incubation period, whereas the O_2 sparged reactors were transferred out of the glove chamber and incubated on the lab bench under aerobic conditions.

During the incubation period, reactors were inverted once a day to increase the contact between the geologic material and groundwater. During quiescent incubation all reactors were covered to minimize photodegradation and incubated at 22 °C (room temperature). Table 2 details the reactor construction, incubation, amendments, and sampling parameters of the desorption test reactors.

2.4 Sampling and Analysis

2.4.1 Baseline and Reactor Sampling

Site geologic materials were sub-sampled for baseline analysis of total metals, CEC, TOC, XRD, and LOI on 21 September 2021. Site materials N-SB-XPW01 (10.0'-12.7') and N-SB-XPW04 (10.0'-15.0') were further sub-sampled for baseline analysis of SPLP on 1 March 2022. Site groundwater was sub-sampled for baseline analysis of dissolved metals including As, B, Li and SO_4^{2-}, DOC, and TDS on 21 September 2021.

The adsorption and desorption control reactors were sampled on Day 0 and Day 7 of their incubation periods. Treatment test reactors from both tests were sampled on Day 7. Samples from the adsorption and desorption tests were submitted for analysis of pH, oxidation reduction potential (ORP), anions (including total volatile fatty acids [VFAs], chloride, nitrite-N, nitrate-N, SO_4^{2-}, and phosphate) and dissolved metals. The controls from the desorption test were additionally submitted for TDS on Day 0.

Site geologic material sub-samples were collected in 250 mL wide-mouth amber glass jars and shipped on ice to ALS Environmental in Waterloo, ON (ALS) or SGS Environmental in Lakefield, ON (SGS). Site groundwater and test reactor samples submitted for pH, ORP, TDS and anions analysis were collected using 30 mL plastic syringes (Fisher Scientific, Whitby, ON) and analysed by SiREM. Samples submitted for dissolved metals were collected as described in Section 2.4.6 and shipped on ice to ALS or SGS for analysis.

2.4.2 Analysis of pH

The pH measurements were performed using an Oakton pH spear with a combination pH electrode (Oakton, Vernon Hills, IL). A 0.5 mL sample was collected (as described in section 2.4.1), placed into a 1.5 mL micro-centrifuge tube, and measured on the lab bench. The pH spear was calibrated at each sampling event according to the manufacturer's instructions using pH 4.0, 7.0 and 10 standards.

2.4.3 Analysis of ORP

The ORP measurements were performed using a YSI Multilab IDS Meter with YSI 4210 ORP glass electrode (Mandel Scientific, Guelph, ON). A 1.2 mL sample was collected (as described in section 2.4.1) and placed in a 5 mL Thermo-Fisher vial. The vial was removed from the glove box and the ORP was measured on the lab bench. The ORP probe was tested at each sampling event according to the manufacturer's instructions using Zobell's solution.

2.4.4 Analysis of TDS

The TDS measurements were performed using a combination conductivity and TDS meter (Hach Model 44600, CO). A 1.5 mL sample was collected (as described in section 2.4.1) and placed in a 5 mL Thermo-Fisher vial. The vial was removed from the glove box and the TDS was measured on the lab bench.

2.4.5 Analysis of Anions and Total VFAs

Anion and total VFA analysis was performed on a Thermo-Fisher ICS-2100 ion chromatograph (IC) equipped with a Thermo-Fisher AS-DV autosampler and an AS18 column. An isocratic separation was performed using 33 millimolar (mM) reagent grade sodium hydroxide eluent generator cartridge (EGC) (Thermo Scientific, Burlington, ON) eluent for 13 minutes (min). One standard was analysed with each set of samples tested to verify the seven-point calibration using external standards of known concentrations. External standards were prepared gravimetrically using chemicals of the highest purity available (Sigma St Louis, MO or Bioshop, Burlington, ON). Data was integrated using Chromeleon 7® Chromatography software (Thermo-Fisher, Burlington, ON). The quantitation limits (QLs) were as follows: 0.07 mg/L total VFAs, 0.07 mg/L chloride, 0.09 mg/L nitrite, 0.09 mg/L nitrate, 0.07 mg/L SO_4^{2-}, 0.07 mg/L phosphate and 0.08 mg/L bromide. The total VFAs value was initially calibrated as lactate, but includes lactate, formate, acetate, propionate, pyruvate, and butyrate.

A 0.5 mL sample was withdrawn from the reactors (as described in section 2.4.1), after which the sample was placed in a 1.5 mL micro-centrifuge tube. Samples were centrifuged for 5 min at

13,000 revolutions per minute (RPM) to remove solids. The supernatant was sub-sampled, diluted 50-fold in deionized (DI) water and placed in a Thermo-Fisher auto sampler vial with a cap that filters the sample during automated injection onto the IC through a 25 microliter (µL) sample loop.

2.4.6 Analysis of Groundwater at ALS and SGS

Dissolved metals and DOC analyses were completed at both ALS and SGS.

Dissolved metals analysis was completed using an inductively coupled plasma-mass spectrometer (ICP-MS). DOC analysis was completed using a modified version of ASTM 1915-13, method E. Reactor samples were collected by decanting the sample into a 30 mL plastic syringe (Fisher Scientific, Whitby, ON) and filtering the sample with a 0.45 micrometer (µm) syringe filter into a 30 mL high-density polyethylene (HDPE) bottle with 150 µL of nitric acid preservative. The samples were then packaged and shipped to ALS or SGS for analysis.

Baseline groundwater samples were submitted to SGS in Lakefield, ON for analysis. However, due to delays in reporting times that SGS could not improve, the analytical laboratory used to complete the dissolved metals analysis for the adsorption and desorption tests was changed to ALS in Waterloo, ON, which could meet the reporting timelines required for the study. Analyses at both labs were completed using similar ICP-MS methodologies.

All groundwater laboratory reports are presented in Appendix B.

2.4.7 Analysis of Geologic Material at ALS and SGS

Total metals and TOC analyses were completed using an acid digestion based on Environmental Protection Agency (EPA) method 3050B, followed by ICP-MS analysis of the extract based on Standard Method 5310C. The total metals and TOC reports from SGS are presented in Appendix C.

CEC analysis was completed using a custom direct method developed by SGS. The CEC report from SGS is presented in Appendix D.

XRD analysis was completed using a custom X-ray crystallography method developed by SGS. LOI analysis was completed using a temperature-controlled furnace along with a crucible to determine the mass prior and post ignition. The XRD and LOI report from SGS is presented in Appendix E.

SPLP analysis was completed using an extract produced by the synthetic precipitation leaching procedure as per EPA 1312 is analysed by Collision/Reaction Cell ICPMS. The extract is filtered through a 0.6-to-0.8-micron glass fibre filter. The SPLP report from ALS is presented in Appendix F.

3. RESULTS

Tables 3, 4, 5, 6 and 7 present a summary of baseline groundwater dissolved metals and DOC results, a summary of baseline geologic material total metals and TOC results, a summary of baseline geologic material CEC results, a summary of baseline geologic material XRD and LOI results, and a summary of baseline geologic material SPLP results.

Tables 8, 9, and 10 present the dissolved metals, anions, and pH and ORP results from the Adsorption Tests.

Table 11 presents the calculated site-specific sorption coefficients for As, B, Li, and SO_4^{2-}. Three types of sorption coefficient were calculated for each analyte in each material combination based on the results from the adsorption tests: a linear coefficient, a Langmuir coefficient, and a Freundlich coefficient. The calculations used to prepare the sorption coefficients are presented in Appendix G.

Tables 12, 13, and 14 present the dissolved metals, anions, and pH, ORP, and TDS results from the Desorption Tests.

Dissolved metals, DOC, TDS, and anion results are reported in units of mg/L. Total metals results are reported in units of micrograms per gram (µg/g). CEC results are presented as milliequivalents per 100 grams of soil (meq/100g). Total SO_4^{2-}, TOC, XRD, and LOI results are presented as a percentage of the total composition of the material. SPLP results are reported in units of µg/L. ORP results are reported in units of millivolts (mV).

*Numbers in brackets represent additional control reactors required for analytical sample volumes.

Notes:

µL - microliter
As - arsenic
B- boron
Cl - chloride
g/L - grams per liter
H - hydrogen
ID - identification
kg - kilogram
L - liter
Li - lithium
mg/L - milligrams per liter
Na - sodium
O - oxygen
ORP - oxidation-reduction potential
$SO4^{2-}$ - sulfate

TABLE 2: SUMMARY OF DESORPTION TEST REACTOR CONTROLS, TREATMENTS, AND AMENDMENTS
Vistra Newton, IL Site

Groundwater Sample ID	Geologic Material Sample ID	Treatment	Description	Number of Replicates	Incubation Period and Sampling Frequency	Microcosm Contents		Amendments		Number of Analyses		
						Groundwater (L)	Saturated Geologic Material (kg)	Oxygen Gas	Hydrogen Gas	Dissolved Metals	Anions	pH/ORP
APW-05	N-SB-02 (65.0'-71.5')	Ambiant Control	Incubated under anaerobic conditions and shaken once daily during incubation	2 (2)*	7 Days (Sampled on Day 0 and 7)	0.1	0.02	--	--	2	2	2
		Oxidizing Conditions	Daily oxygen gas addition and incubated under aerobic conditions and shaken once daily during incubation	2	7 Days (Sampled on Day 7)	0.1	0.02	Amended with 5 mL of pure oxygen gas every day.	--	2	2	2
		Reducing Conditions	Daily hydrogen gas addition and incubated under anaerobic conditions and shaken once daily during incubation	2		0.1	0.02	--	Amended with 5 mL of pure hydrogen gas every day.	2	2	2
	N-SB-02 (12.5'-20.0')	Ambiant Control	Incubated under anaerobic conditions and shaken once daily during incubation	2 (2)*	7 Days (Sampled on Day 0 and 7)	0.1	0.02	--	--	2	2	2
		Oxidizing Conditions	Daily oxygen gas addition and incubated under aerobic conditions and shaken once daily during incubation	2	7 Days (Sampled on Day 7)	0.1	0.02	Amended with 5 mL of pure oxygen gas every day.	--	2	2	2
		Reducing Conditions	Daily hydrogen gas addition and incubated under anaerobic conditions and shaken once daily during incubation	2		0.1	0.02	--	Amended with 5 mL of pure hydrogen gas every day.	2	2	2

*Numbers in brackets represent additional control reactors required for analytical sample volumes.

Notes:

ID - identification
kg - kilogram
L - liter
mL - milliliters
ORP - oxidation-reduction potential

TABLE 3: SUMMARY OF BASELINE GROUNDWATER TOTAL DISSOLVED METALS, DOC and TDS RESULTS

Vistra Newton, IL Site

Groundwater Sample ID	Date	Dissovled Arsenic	Dissolved Boron	Dissolved Lithium	Dissolved Sulfate	DOC	TDS	Comments

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	Arsenic (As)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Boron (B)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Calcium (Ca)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Lithium (Li)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Magnesium (Mg)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Manganese (Mn)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Silicon (Si)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Sodium (Na)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Strontium (Sr)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Sulfur (S)-Dissolved	MS-B	L2686539-1, -2, -3, -4
Matrix Spike	Uranium (U)-Dissolved	MS-B	L2686539-1, -2, -3, -4

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-CCMS-WT	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

Matrix Spike	Uranium (U)-Dissolved	MS-B	L2688199-21, -22, -23, -24

Sample Parameter Qualifier key listed:

Qualifier	Description
DLHC	Detection Limit Raised: Dilution required due to high concentration of test analyte(s).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
MET-D-CCMS-WT	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Analysis conducted in accordance with the Protocol for Analytical Methods Used in the Assessment of Properties under Part XV.1 of the Environmental Protection Act (July 1, 2011).

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

Chain of Custody Numbers:

1 2

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Guelph ON N1G 3Z2
Contact: Michael Healey

Legend:

Limit	ALS Control Limit (Data Quality Objectives)
DUP	Duplicate
RPD	Relative Percent Difference
N/A	Not Available
LCS	Laboratory Control Sample
SRM	Standard Reference Material
MS	Matrix Spike
MSD	Matrix Spike Duplicate
ADE	Average Desorption Efficiency
MB	Method Blank
IRM	Internal Reference Material
CRM	Certified Reference Material
CCV	Continuing Calibration Verification
CVS	Calibration Verification Standard
LCSD	Laboratory Control Sample Duplicate

Sample Parameter Qualifier Definitions:

Qualifier	Description
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

C-O-C number	: ----	Issue Date	: 29-Mar-2022 10:08
Sampler	: Rachel Hallman		
Site	: ----		
Quote number	: 2022 SOA		
No. of samples received	: 4		
No. of samples analysed	: 4		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Certificate of Analysis contains the following information:

- General Comments
- Analytical Results

Additional information pertinent to this report will be found in the following separate attachments: Quality Control Report, QC Interpretive report to assist with Quality Review and Sample Receipt Notification (SRN).

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*
Greg Pokocky	Supervisor - Inorganic	Metals, Waterloo, Ontario

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLHC	*Detection Limit Raised: Dilution required due to high concentration of test analyte(s).*

Sampler	: Rachel Hallman		
Site	: ----		
Quote number	: 2022 SOA		
No. of samples received	: 4		
No. of samples analysed	: 4		

This report is automatically generated by the ALS LIMS (Laboratory Information Management System) through evaluation of Quality Control (QC) results and other QA parameters associated with this submission, and is intended to facilitate rapid data validation by auditors or reviewers. The report highlights any exceptions and outliers to ALS Data Quality Objectives, provides holding time details and exceptions, summarizes QC sample frequencies, and lists applicable methodology references and summaries.

Key

Anonymous: Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances.
DQO: Data Quality Objective.
LOR: Limit of Reporting (detection limit).
RPD: Relative Percent Difference.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Summary of Outliers

Outliers : Quality Control Samples

- No Method Blank value outliers occur.
- No Duplicate outliers occur.
- No Laboratory Control Sample (LCS) outliers occur
- No Matrix Spike outliers occur.
- No Test sample Surrogate recovery outliers exist.

Outliers: Reference Material (RM) Samples

- No Reference Material (RM) Sample outliers occur.

Outliers : Analysis Holding Time Compliance (Breaches)

- No Analysis Holding Time Outliers exist.

Outliers : Frequency of Quality Control Samples

- No Quality Control Sample Frequency Outliers occur.

Analysis Holding Time Compliance

This report summarizes extraction / preparation and analysis times and compares each with ALS recommended holding times, which are selected to meet known provincial and /or federal requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by organizations such as CCME, US EPA, APHA Standard Methods, ASTM, or Environment Canada (where available). Dates and holding times reported below represent the first dates of extraction or analysis. If subsequent tests or dilutions exceeded holding times, qualifiers are added (refer to COA).

If samples are identified below as having been analyzed or extracted outside of recommended holding times, measurement uncertainties may be increased, and this should be taken into consideration when interpreting results.

Where actual sampling date is not provided on the chain of custody, the date of receipt with time at 00:00 is used for calculation purposes.

Where only the sample date without time is provided on the chain of custody, the sampling date at 00:00 is used for calculation purposes.

Matrix: **Water**

Evaluation: × = Holding time exceedance ; ✓ = Within Holding Time

Legend & Qualifier Definitions

Rec. HT: ALS recommended hold time (see units).

Quality Control Parameter Frequency Compliance

The following report summarizes the frequency of laboratory QC samples analyzed within the analytical batches (QC lots) in which the submitted samples were processed. The actual frequency should be greater than or equal to the expected frequency.

Matrix: **Water**

Evaluation: × = *QC frequency outside specification*; ✓ = *QC frequency within specification.*

Quality Control Sample Type			Count		Frequency (%)		
Analytical Methods	*Method*	*QC Lot #*	*QC*	*Regular*	*Actual*	*Expected*	*Evaluation*
Laboratory Duplicates (DUP)							
Dissolved Metals in Water by CRC ICPMS	E421	439609	1	4	25.0	5.0	✓
Laboratory Control Samples (LCS)							
Dissolved Metals in Water by CRC ICPMS	E421	439609	1	4	25.0	5.0	✓
Method Blanks (MB)							
Dissolved Metals in Water by CRC ICPMS	E421	439609	1	4	25.0	5.0	✓
Matrix Spikes (MS)							
Dissolved Metals in Water by CRC ICPMS	E421	439609	1	4	25.0	5.0	✓

Methodology References and Summaries

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Reference methods may incorporate modifications to improve performance (indicated by "mod").

Analytical Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Dissolved Metals in Water by CRC ICPMS	E421 Waterloo - Environmental	Water	APHA 3030B/EPA 6020B (mod)	Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by Collision/Reaction Cell ICPMS. Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

Preparation Methods	Method / Lab	Matrix	Method Reference	Method Descriptions
Dissolved Metals Water Filtration	EP421 Waterloo - Environmental	Water	APHA 3030B	Water samples are filtered (0.45 um), and preserved with HNO3.

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Services number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percentage Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test specific).

Sub-Matrix: **Water**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

General Comments

The analytical methods used by ALS are developed using internationally recognized reference methods (where available), such as those published by US EPA, APHA Standard Methods, ASTM, ISO, Environment Canada, BC MOE, and Ontario MOE. Refer to the ALS Quality Control Interpretive report (QCI) for applicable references and methodology summaries. Reference methods may incorporate modifications to improve performance.

Where a reported less than (<) result is higher than the LOR, this may be due to primary sample extract/digestate dilution and/or insufficient sample for analysis.

Where the LOR of a reported result differs from standard LOR, this may be due to high moisture content, insufficient sample (reduced weight employed) or matrix interference.

Please refer to Quality Control Interpretive report (QCI) for information regarding Holding Time compliance.

Key : CAS Number: Chemical Abstracts Services number is a unique identifier assigned to discrete substances
LOR: Limit of Reporting (detection limit).

Unit	*Description*
-	No Unit
mg/L	milligrams per litre

<: less than.

>: greater than.

Surrogate: An analyte that is similar in behavior to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED on SRN or QCI Report, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Qualifiers

Qualifier	*Description*
DLHC	*Detection Limit Raised: Dilution required due to high concentration of test analyte(s).*

ALS Environmental

QUALITY CONTROL REPORT

Work Order	: **WT2201892-AA**	Page	: 1 of 10
Amendment	: **1**		
Client	: SiREM	Laboratory	: Waterloo - Environmental
Contact	: Rachel Hallman	Account Manager	: Gayle Braun
Address	: 130 Stone Road West Guelph ON Canada N1G 3Z2	Address	: 60 Northland Road, Unit 1 Waterloo, Ontario Canada N2V 2B8
Telephone	: 519 822 2265	Telephone	: +1 519 886 6910
Project	: Newton	Date Samples Received	: 31-Mar-2022 14:00
PO	: ----	Date Analysis Commenced	: 01-Apr-2022
C-O-C number	: ----	Issue Date	: 27-Jul-2022 10:05
Sampler	: ----		
Site	: ----		
Quote number	: 2022 SOA		
No. of samples received	: 12		
No. of samples analysed	: 12		

This report supersedes any previous report(s) with this reference. Results apply to the sample(s) as submitted. This document shall not be reproduced, except in full.

This Quality Control Report contains the following information:

- Laboratory Duplicate (DUP) Report; Relative Percent Difference (RPD) and Data Quality Objectives
- Matrix Spike (MS) Report; Recovery and Data Quality Objectives
- Method Blank (MB) Report; Recovery and Data Quality Objectives
- Laboratory Control Sample (LCS) Report; Recovery and Data Quality Objectives

Signatories

This document has been electronically signed by the authorized signatories below. Electronic signing is conducted in accordance with US FDA 21 CFR Part 11.

Signatories	*Position*	*Laboratory Department*

General Comments

The ALS Quality Control (QC) report is optionally provided to ALS clients upon request. ALS test methods include comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against predetermined Data Quality Objectives (DQOs) to provide confidence in the accuracy of associated test results. This report contains detailed results for all QC results applicable to this sample submission. Please refer to the ALS Quality Control Interpretation report (QCI) for applicable method references and methodology summaries.

Key :

Anonymous = Refers to samples which are not part of this work order, but which formed part of the QC process lot.
CAS Number = Chemical Abstracts Service number is a unique identifier assigned to discrete substances.
DQO = Data Quality Objective.
LOR = Limit of Reporting (detection limit).
RPD = Relative Percent Difference
# = Indicates a QC result that did not meet the ALS DQO.

Workorder Comments

Holding times are displayed as "---" if no guidance exists from CCME, Canadian provinces, or broadly recognized international references.

Laboratory Duplicate (DUP) Report

A Laboratory Duplicate (DUP) is a randomly selected intralaboratory replicate sample. Laboratory Duplicates provide information regarding method precision and sample heterogeneity. ALS DQOs for Laboratory Duplicates are expressed as test-specific limits for Relative Percent Difference (RPD), or as an absolute difference limit of 2 times the LOR for low concentration duplicates within ~ 4-10 times the LOR (cut-off is test-specific).

Sub-Matrix: **Water**

Method Blank (MB) Report

A Method Blank is an analyte-free matrix that undergoes sample processing identical to that carried out for test samples. Method Blank results are used to monitor and control for potential contamination from the laboratory environment and reagents. For most tests, the DQO for Method Blanks is for the result to be < LOR.

Laboratory Control Sample (LCS) Report

A Laboratory Control Sample (LCS) is an analyte-free matrix that has been fortified (spiked) with test analytes at known concentration and processed in an identical manner to test samples. LCS results are expressed as percent recovery, and are used to monitor and control test method accuracy and precision, independent of test sample matrix.

Sub-Matrix: **Water**

					Laboratory Control Sample (LCS) Report				
					Spike	Recovery (%)	Recovery Limits (%)

Matrix Spike (MS) Report

A Matrix Spike (MS) is a randomly selected intra-laboratory replicate sample that has been fortified (spiked) with test analytes at known concentration, and processed in an identical manner to test samples. Matrix Spikes provide information regarding analyte recovery and potential matrix effects. MS DQO exceedances due to sample matrix may sometimes be unavoidable; in such cases, test results for the associated sample (or similar samples) may be subject to bias. ND – Recovery not determined, background level >= 1x spike level.

Sub-Matrix: **Water**

APPENDIX E:
SGS Geologic Material XRD and LOI Laboratory Report

Quantitative X-Ray Diffraction by Rietveld Refinement

Report Prepared for:	*Environmental Services*
Project Number/ LIMS No.	*Custom XRD/MI4503-OCT21*
Sample Receipt:	*October 4, 2021*
Sample Analysis:	*October 8, 2021*
Reporting Date:	*November 2, 2021*

Instrument:	BRUKER AXS D8 Advance Diffractometer
Test Conditions:	Co radiation, 35 kV, 40 mA Regular Scanning: Step: 0.02°, Step time: 1s, 2θ range: 3-80°
Interpretations :	PDF2/PDF4 powder diffraction databases issued by the International Center for Diffraction Data (ICDD). DiffracPlus Eva and Topas software.
Detection Limit :	0.5-2%. Strongly dependent on crystallinity.

ACCREDITATION: SGS Minerals Services Lakefield is accredited to the requirements of ISO/IEC 17025 for specific tests as listed on our scope of accreditation, including geochemical, mineralogical and trade mineral tests. To view a list of the accredited methods, please visit the following website and search SGS Canada - Minerals Services - Lakefield: http://palcan.scc.ca/SpecsSearch/GLSearchForm.do.

Method Summary

The Rietveld Method of Mineral Identification by XRD (ME-LR-MIN-MET-MN-D05) method used by SGS Minerals Services is accredited to the requirements of ISO/IEC 17025.

Mineral Identification and Interpretation:

Mineral identification and interpretation involves matching the diffraction pattern of an unknown material to patterns of single-phase reference materials. The reference patterns are compiled by the Joint Committee on Powder Diffraction Standards - International Center for Diffraction Data (JCPDS-ICDD) database and released on software as Powder Diffraction Files (PDF).

Interpretations do not reflect the presence of non-crystalline and/or amorphous compounds, except when internal standards have been added by request. Mineral proportions may be strongly influenced by crystallinity, crystal structure and preferred orientations. Mineral or compound identification and quantitative analysis results should be accompanied by supporting chemical assay data or other additional tests.

Quantitative Rietveld Analysis:

Quantitative Rietveld Analysis is performed by using Topas 4.2 (Bruker AXS), a graphics based profile analysis program built around a non-linear least squares fitting system, to determine the amount of different phases present in a multicomponent sample. Whole pattern analyses are predicated by the fact that the X-ray diffraction pattern is a total sum of both instrumental and specimen factors. Unlike other peak intensity-based methods, the Rietveld method uses a least squares approach to refine a theoretical line profile until it matches the obtained experimental patterns.

Rietveld refinement is completed with a set of minerals specifically identified for the sample. Zero values indicate that the mineral was included in the refinement calculations, but the calculated concentration was less than 0.05wt%. Minerals not identified by the analyst are not included in refinement calculations for specific samples and are indicated with a dash.

Summary of Rietveld Quantitative Analysis X-Ray Diffraction Results

TOTAL	100	100	100	100	100	100	100	100	100	100

Zero values indicate that the mineral was included in the refinement, but the calculated concentration is below a measurable value.

Dashes indicate that the mineral was not identified by the analyst and not included in the refinement calculation for the sample.

The weight percent quantities indicated have been normalized to a sum of 100%. The quantity of amorphous material has not been determined.

Mineral List

Mineral/Compound	Formula
Quartz	SiO_2

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
LEACH-MSPLP-WT	Waste	Modified SPLP Extraction	E9003

A Sample (100g) of soil is leached for 18 +/- 2 hours with 2.0 liters of splp leaching fluid #2 (pH = 5). For the analysis of metals, the leachate is filtered through a 0.45um filter using a metals free filtering system prior to digestion and analysis.

MET-SPLP-WT	Waste	SPLP Leachable Metals	EPA 200.8

An extract produced by the Synthetic Precipitation Leaching Procedure (SPLP) as per EPA 1312 or Ontario MECP E9003 is analyzed by Collision/Reaction Cell ICPMS. The extract is filtered through a 0.6 to 0.8 micron glass fibre filter for Method 1312 or through a 0.45um filter for Method E9003.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WT	ALS ENVIRONMENTAL - WATERLOO, ONTARIO, CANADA

GLOSSARY OF REPORT TERMS

Surrogates are compounds that are similar in behaviour to target analyte(s), but that do not normally occur in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery. In reports that display the D.L. column, laboratory objectives for surrogates are listed there.
mg/kg - milligrams per kilogram based on dry weight of sample
mg/kg wwt - milligrams per kilogram based on wet weight of sample
mg/kg lwt - milligrams per kilogram based on lipid weight of sample
mg/L - unit of concentration based on volume, parts per million.
< - Less than.
D.L. - The reporting limit.
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Sample Parameter Qualifier Definitions:

Qualifier	Description
RPD-NA	Relative Percent Difference Not Available due to result(s) being less than detection limit.

Hold Time Exceedances:

All test results reported with this submission were conducted within ALS recommended hold times.

ALS recommended hold times may vary by province. They are assigned to meet known provincial and/or federal government requirements. In the absence of regulatory hold times, ALS establishes recommendations based on guidelines published by the US EPA, APHA Standard Methods, or Environment Canada (where available). For more information, please contact ALS.

The ALS Quality Control Report is provided to ALS clients upon request. ALS includes comprehensive QC checks with every analysis to ensure our high standards of quality are met. Each QC result has a known or expected target value, which is compared against pre-determined data quality objectives to provide confidence in the accuracy of associated test results.

Please note that this report may contain QC results from anonymous Sample Duplicates and Matrix Spikes that do not originate from this Work Order.

APPENDIX G:
Sorption Coefficient Calculations

The site-specific sorption coefficients (linear, Langmuir, and Freundlich) presented Table 11 were calculated as follows below.

To calculate the site-specific sorption coefficients, the equilibrium concentrations of each analyte in the groundwater and geologic material must be known. Equilibrium aqueous concentrations were measured directly after the reaction period. Equilibrium geologic material concentrations were calculated using the baseline geologic material concentrations, the time zero aqueous concentrations and the equilibrium aqueous concentrations as follows:

$$q_e = \frac{q_{t=0} \cdot m_s + (C_{t=0} - C_e) \cdot v_{aq}}{m_s}$$

Where,

q_e is the concentration of a given analyte in the geologic material in g/kg at equilibrium

$q_{t=0}$ is the concentration of a given analyte in the geologic material in g/kg at baseline

C_e is the concentration of a given analyte in the aqueous phase in g/L at equilibrium

$C_{t=0}$ is the concentration of a given analyte in the aqueous phase in g/L at the start of the reaction period, after spiking

m_s is the dry mass of the geologic material in a given reactor, in kg

v_{aq} is the volume of groundwater in a given reactor, in L

Linear Sorption Coefficient:

The concentration of a given analyte in the geologic material is plotted against the concentration of the analyte in the aqueous phase. The slope of the linear trendline is the linear sorption coefficient (K_D).

$$q_e = C_e \cdot K_D + b$$

Where,

q_e is the concentration of a given analyte in the geologic material in g/kg at equilibrium

C_e is the concentration of a given analyte in the aqueous phase in g/L at equilibrium

K_D is the linear sorption coefficient

b is the y-intercept of the plot

Langmuir Sorption Coefficient:

The Langmuir model of sorption can be expressed as follows:

$$q_e = \frac{q_m \cdot K_L \cdot C_e}{1 + K_L \cdot C_e}$$

Where,

q_e is the concentration of a given analyte in the geologic material in g/kg

C_e is the concentration of a given analyte in the aqueous phase in g/L

K_L is the Langmuir sorption coefficient

q_m is the maximum concentration possible to be sorbed to the geologic material in g/kg

This relationship can be linearized as follows:

$$\frac{C_e}{q_e} = \frac{1}{K_L \cdot q_m} + \frac{C_e}{q_m}$$

Therefore, the equilibrium aqueous phase concentration divided by the equilibrium geologic material concentration (C_e/q_e) can be plotted against the equilibrium aqueous phase concentration (C_e) and:

$$K_L = \frac{1}{y - intercept \cdot q_m}$$

$$q_m = \frac{1}{slope}$$

Freundlich Sorption Coefficient

The Freundlich model of sorption can be expressed as follows:

$$q_e = K_F \cdot (C_e)^{\frac{1}{n}}$$

Where,

q_e is the concentration of a given analyte in the geologic material in g/kg

C_e is the concentration of a given analyte in the aqueous phase in g/L

K_F is the Freundlich sorption coefficient

n is a Site-specific sorption constant

This relationship can be linearized as follows:

$$\log q_e = \frac{\log K_F + 1}{n \cdot \log C_e}$$

Therefore, the logarithm of the equilibrium geologic material concentration ($\log(q_e)$) can be plotted against the logarithm of the equilibrium aqueous phase concentration ($\log(C_e)$) and:

$$K_F = e^{intercept}$$

$$n = \frac{1}{slope}$$
