Re: Newton Power Plant Primary Ash Pond; IEPA ID # W0798070001-01

Dear Mr. LeCrone:

In accordance with 35 I.A.C. § 845.200, Illinois Power Generating Company (IPGC) is submitting a supplement to the previously submitted operating permit application for the Newton Power Plant Primary Ash Pond (IEPA ID # W0798070001-01) to address the corrective action requirements of Part 845.

IPGC previously submitted an operating permit application for Newton Power Plant Primary Ash Pond on October 25, 2021. The enclosed supplemental information is being submitted in accordance with 35 I.A.C. § 845.200(a)(3) in order to "[modify] the facility's operating permit when the approved corrective action does not require the modification of the CCR surface impoundment." This amendment includes a corrective action plan containing corrective action alternatives analysis, groundwater modeling, and corrective action groundwater monitoring program. One hardcopy is provided with this submittal.

Sincerely,

Phil Morris
Sr. Director, Environmental

Visual Road Map for Corrective Action
Supplement to Operating Permit Application
Newton Power Plant, Primary Ash Pond
Newton, IL

CORRECTIVE ACTION PLAN

§845.670
Identifies the selected remedy based on the results of the Corrective Measures Assessment

Appendix A
CORRECTIVE ACTION ALTERNATIVE ANALYSIS (CAAA)

§845.670(e)
Evaluation of potential viable corrective actions identified in the Corrective Measures Assessment

Appendix B
CORRECTIVE ACTION GROUNDWATER MONITORING PLAN

§845.680(a)(1)
Plan that establishes how data will be collected, documented, and evaluated to assess remedy effectiveness

Appendix A
HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT

§845.670(f)(4)
Evaluation of potential risks to human and ecological receptors

Appendix B
CAAA SUPPORTING INFORMATION REPORT

§845.670(e)
Information to support preparation of CAAA

Appendix C
CORRECTIVE MEASURES ASSESSMENT

§845.660
Assessment of potential corrective measure technologies to address GWPS exceedances at the CCR surface impoundment

Appendix D
NATURE AND EXTENT REPORT AND ADDENDUM

§845.650(d)(1)
Documents the nature and extent of constituents detected above the GWPS that are attributable to the CCR surface impoundment

Appendix E
GROUNDWATER POLISHING REPORT

§845.220(c)(2)
Presents results of geochemical modeling used to evaluate chemical mechanisms on groundwater polishing under current conditions and after implementation of the corrective measure

Appendix A
FEASIBILITY LEVEL DRAWINGS

Conceptual design drawings showing approximate extents and details of alternatives presented in the CAAA

Appendix B.1
GROUNDWATER MODELING TECHNICAL MEMORANDUM

§845.220(c)(2)
Presents additional groundwater modeling simulations and incorporates data collected since 2022 modeling (Appendix B.2) to support alternatives presented in the CAAA

Appendix B.2
GROUNDWATER MODELING REPORT VERSION 1

§845.220(c)(2)
Presents results of 2022 MODFLOW and MT3DMS groundwater flow and transport models to evaluate potential alternatives

Appendix C
LABOR/MILEAGE ESTIMATES

Detailed material quantity, labor and mileage estimates for alternatives presented in the CAAA

Section 845.620 - Hydrogeologic Site Characterization								
845.620	Hydrogeologic Site Characterization	---	---	---	x			HCR was submitted on July 28, 2022 as Attachment B to CP application.
Section 845.660 - Assessment of Corrective Measures								
845.660	Assessment of Corrective Measures	CAAA	---	27	x			Submitted on April 3, 2024. Also attached as Appendix C in CAAA which is Appendix A of the CAP
Section 845.670 - Corrective Action Plan								
845.670(a)	The owner or operator must prepare a semi-annual report describing the progress in selecting a remedy and developing a CAP. The semi-annual report must be submitted to IEPA and placed in the operating record as required by 35 I.A.C. § 845.800(d)(17).							Submitted on October 3, 2024
845.670(b)	Within one year after completing the assessment of corrective measures as specified in 35 I.A.C. § 845.660, and after completion of the public meeting in 35 I.A.C. § 845.660(d), the owner or operator of the CCR surface impoundment must submit, in a CP application [or modification to the facility's operating permit] to IEPA, a CAP that identifies the selected remedy. This requirement applies in addition to, not in place of, any applicable standards under any other State or federal law.	Supplement to Operating Permit Application	---	1			x	A corrective action CP is not required when the proposed corrective action does not require modification of the CCR SI or the installation or modification of related treatment or mitigation facilities per 845.200(a)(3)
845.670(c)	The CAP must meet the following requirements:							
845.670(c)(1)	Be based on the results of the CMA conducted under 35 I.A.C. § 845.660;	CMA	---	353			x	
845.670(c)(2)	Identify a selected remedy that at a minimum, meets the standards listed in subsection (d);	CAAA	Section 2	52			x	
845.670(c)(3)	Contain the corrective action alternatives analysis specified in subsection (e); and	CAAA	Section 2	52			x	
845.670(c)(4)	Contain proposed schedules for implementation, including an analysis of the factors in subsection (f).	CAP	Table 1	25			x	
845.670(d)	The selected remedy in the CAP must:							
845.670(d)(1)	Be protective of human health and the environment;	CAAA	Section 2	52			x	
845.670(d)(2)	Attain the GWPS specified in 35 I.A.C. § 845.600;	Groundwater Modeling Technical Memorandum	Section 4	174			x	
845.670(d)(3)	Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in 35 I.A.C. § 845.600 into the environment;	CAAA	Section 2	52			x	
845.670(d)(4)	Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, taking into account factors such as avoiding inappropriate disturbance of sensitive ecosystems; and	CAAA	Section 2.5	72			x	
845.670(d)(5)	Comply with standards for management of wastes as specified in 35 I.A.C. § 845.680(d).	CAAA	Section 2	52			x	
845.670(e)	CAAA. In selecting a remedy that meets the standards of subsection (d), the owner or operator of the CCR surface impoundment must consider the following evaluation factors:							
845.670(e)(1)	The long- and short-term effectiveness and protectiveness of each potential remedy, along with the degree of certainty that the remedy will prove successful based on consideration of the following:	CAAA	Section 2.2	57			x	
845.670(e)(1)(A)	Magnitude of reduction of existing risks;	CAAA	Section 2.2	57			x	
845.670(e)(1)(B)	Magnitude of residual risks in terms of likelihood of further releases due to CCR remaining following implementation of a remedy;	CAAA	Section 2.2	57			x	
845.670(e)(1)(C)	The type and degree of long-term management required, including monitoring, operation, and maintenance;	CAAA	Section 2.2	57			x	
845.670(e)(1)(D)	Short-term risks that might be posed to the community or the environment during implementation of a remedy, including potential threats to human health and the environment associated with excavation, transportation, and re-disposal of contaminants;	CAAA	Section 2.2	57			x	
845.670(e)(1)(E)	Time until GWPS in 35 I.A.C. § 845.600 are achieved;	CAAA	Section 2.2	57			x	
845.670(e)(1)(F)	The potential for exposure of humans and environmental receptors to remaining wastes, considering the potential threat to human health and the environment associated with excavation, transportation, re-disposal, containment, or changes in groundwater flow;	CAAA	Section 2.2	57			x	
845.670(e)(1)(G)	The long-term reliability of the engineering and institutional controls, including an analysis of any off-site, nearby destabilizing activities; and	CAAA	Section 2.2	57			x	
845.670(e)(1)(H)	Potential need for replacement of the remedy.	CAAA	Section 2.2	57			x	
845.670(e)(2)	The effectiveness of the remedy in controlling the source to reduce further releases based on consideration of each of the following potential factors:	CAAA	Section 2.2.2	58			x	
845.670(e)(2)(A)	The extent to which containment practices will reduce further releases; and	CAAA	Section 2.2.2	58			x	
845.670(e)(2)(B)	The extent to which treatment technologies may be used.	CAAA	Section 2.2.2	58			x	
845.670(e)(3)	The ease or difficulty of implementing each potential remedy based on consideration of the following types of factors:	CAAA	Section 2.3	68			x

1. INTRODUCTION

1.1 Plant and Site Information

Illinois Power Generation Company (IPGC) is the owner of the active coal-fired Newton Power Plant (NPP), also referred to as the Newton Power Station (NEW), in Newton, Illinois. IPGC intends to complete groundwater corrective action for the Primary Ash Pond (PAP), coal combustion residuals (CCR) surface impoundment (SI), which is identified by Illinois Environmental Protection Agency (IEPA) identification (ID) number (No.) W0798070001-01, CCR Unit ID No. 501, and National Inventory of Dams (NID) No. IL50719. This Corrective Action Plan (CAP) has been prepared for the PAP at the NPP under the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments [1] and requirements of the Title 40 Code of Federal Regulations (40 C.F.R.) § 257 Subpart D, herein referred to as the Federal CCR Rule [2].

1.2 Organization of the Corrective Action Plan

This CAP is organized in the following manner:

- **Section 1** includes an introduction to the PAP, lists the status of other 35 I.A.C. § 845 permit applications submitted to IEPA, identifies the selected remedy, and provides a narrative of remedy construction;
- **Section 2** includes an overview of the Corrective Action process, including the results of the Corrective Measures Assessment (CMA) and Corrective Action Alternatives Analysis (CAAA);
- **Section 3** provides the CAP requirements, the selected remedy, an evaluation of effectiveness and an implementation schedule, as required by 35 I.A.C. § 845.670; and
- **Section 4** includes reference documents used in the development of this CAP.

This CAP was prepared as a supplement to the submitted Operating Permit (OP) application for the PAP as required by 35 I.A.C. § 845.200(a)(3).

1.3 Permit Status

The following 35 I.A.C. § 845 permit applications have previously been submitted to IEPA by IPGC for the PAP:

- An OP application, as required by 35 I.A.C. § 845.200(a)(3), was submitted on October 25, 2021 [3].
- A Construction Permit (CP) application for final closure of the PAP, as required by 35 I.A.C. § 845.220 [4], including a CCR Surface Impoundment Final Closure Plan, as required by 35 I.A.C. § 845.720, was submitted on July 28, 2022 [5]; a revised Final Closure Plan [6] is being provided in an amended CP application that will be provided to IEPA on April 1, 2025.

The Final Closure Plan selected closure-in-place (CIP) with a consolidate-and-cap approach as the most appropriate closure method for the PAP.

As of the date of this CAP, IPGC's OP and final closure CP applications for the PAP are pending with IEPA.

1.4 Selected Corrective Action Remedy

Groundwater Polishing (GWP) following source control (*i.e.,* consolidate-and-cap) presented within the Final Closure Plan [5, 6], has been identified as the most appropriate remedy for the PAP, based on the CAAA provided in **Appendix A**. Potential remedies evaluated in the CAAA included Source Control with GWP and Source Control with Groundwater Extraction (GWE).

The CAAA, which was prepared by Gradient Corporation (Gradient), was based on a CAAA Supporting Information Report (CAAA-SIR) that was prepared by Ramboll Americas Engineering Solutions, Inc. (Ramboll) and is attached to the CAAA. The CAAA-SIR includes the results of groundwater modeling and feasibility-level design information for each remedy.

A Groundwater Polishing Evaluation Report is also attached to the CAAA. This report presents results from geochemical modeling of exceedance parameters addressed at PAP by the CAP. Geochemical modeling supports the assessment of groundwater polishing as a component of the proposed corrective action by evaluating the potential for chemical attenuation of constituents of concern (COCs) before and after source control as a means of contextualizing the times to meet GWPS estimated in the flow and transport model.

1.4.1 Narrative Description of Selected Corrective Action Remedy

Corrective action will consist of source control, as outlined in the Final Closure Plan for the PAP [5, 6]. The source control will be followed by GWP. The proposed closure exceeds the minimum Closure Performance Standards listed in 35 I.A.C. § 845.750. The closure will include removing free liquids in accordance with the performance standard in 35 I.A.C. § 845. The closure will control infiltration in accordance with the performance standard in 35 I.A.C. § 845, thus removing the hydraulic head that can force leachate into subsurface soils and is the mechanism that can drive risk (United States Environmental Protection Agency [7].

> *EPA's risk assessment shows that the highest risks are associated with CCR surface impoundments due to the hydraulic head imposed by impounded water. Dewatered CCR surface impoundments will no longer be subjected to hydraulic head so the risk of releases, including the risk that the unit will leach into the groundwater, would be no greater than those from CCR landfills.*

The PAP will be closed using a consolidate-and-cap approach consisting of excavating nearly 3.6 million cubic yards of CCR and placing it in a consolidated CCR footprint at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table [6]. The consolidated CCR will be covered with an alternate geomembrane final cover system having performance that exceeds the 35 I.A.C. § 845.750(c)(2) minimum final cover requirements. The proposed source control is predicted to reduce water flux into and out of the PAP by greater than 99 percent and allow the GWPS to be achieved within approximately 34 years [8]. These source control activities will serve as the primary groundwater corrective measure at the PAP.

1.4.1.1 Narrative Discussion of Remedy Design and Function

The USEPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives [9]. Natural geochemical processes are appropriate as a "polishing step" for residual plume management after effective source control implementation

(*i.e.*, groundwater polishing) because there are no risks to receptors and the contaminant plume is not expanding. Groundwater polishing will achieve the GWPS by natural physical and chemical mechanisms within the groundwater which reduce the concentrations of COCs. Therefore, selection of a groundwater monitoring network, groundwater monitoring, and adaptive management are critical components of remedy design and function which are further described in **Section 1.4.2**.

1.4.2 Narrative Description of Proposed Groundwater Monitoring

Corrective action groundwater monitoring will be conducted during remedy operation to evaluate the effectiveness of the corrective action remedy and whether groundwater concentrations are achieving the GWPS as predicted by the groundwater model. Groundwater data collected as part of the monitoring program will be analyzed to determine if the remedy is on track to meet GWPS and to inform adaptive management decisions if performance metrics are not achieved. A Corrective Action Groundwater Monitoring Plan (GMP) with details on how the groundwater monitoring network will be monitored, how the data will be analyzed, and what will trigger adaptive site management directions is included as **Appendix B**. Information associated with these activities is described below.

- Regular groundwater monitoring will be conducted utilizing a corrective action groundwater monitoring network designed in accordance with 35 I.A.C. § 845.680(c).
- Laboratory parameters include major ions for evaluating groundwater chemistry and COCs (*i.e.*, reported exceedances in accordance with the Operating GMP) the corrective action is intended to address. Sampling to evaluate corrective action effectiveness will begin the quarter after the corrective action remedy is implemented and commissioned. Samples will be collected on a quarterly basis initially and potentially reduced to a semiannual basis once five years of monitoring have occurred, in accordance with 35 I.A.C. § 845.650(b)(4). Monitoring results will be submitted to IEPA for each monitoring event, in addition to an Annual Groundwater Monitoring and Corrective Action Report, in accordance with 35 I.A.C. § 845.610(e).
- Routine maintenance of the monitoring well network will include inspecting the wells, making repairs to the wells (as needed) and rehabilitating and/or replacing wells to improve performance (as needed).
- Adaptive site management strategies will be employed as an integral part of ongoing corrective action at the PAP. The adaptive site management approach will allow timely incorporation of new site information to ensure the achievement of the GWPS. The effectiveness of the remedy at each phase is evaluated using performance metrics designed to assess the goals of that phase. Performance metrics answer questions designed to evaluate multiple aspects of remedy effectiveness with the ultimate goal of holistically guiding management decisions [10]. The goals and performance metrics of each phase of remedy evaluation are presented in Section 3 of the Corrective Action GMP (**Appendix B**).
- Documentation of remedy progress metrics will be provided in the Annual Groundwater Monitoring and Corrective Action Report beginning after the second year of data collection: a minimum of eight data points is required to complete meaningful statistical analysis required for evaluation of the remedy progress metrics, which will be available after two years of quarterly sampling. Per USEPA guidance [10], a thorough review of corrective action progress and remedy effectiveness will be conducted every five years. A Five-Year Annual Groundwater

Monitoring and Corrective Action Report will evaluate the comprehensive data set and, if triggered by the results of the remedy progress evaluation metrics, evaluate whether adaptive management actions are needed. The five-year time frame allows adaptive management decisions to be based on a robust data sufficient to complete meaningful statistical analysis while remaining responsive to changing site conditions [10].

- Corrective Action Confirmation Monitoring and Completion
  - Per 35 I.A.C. § 845.680(c), corrective action is considered complete when compliance with the GWPS has been demonstrated "at all points within the plume of contamination that lies beyond the waste boundary […] for a period of three consecutive years". At that time, an attainment evaluation will be implemented. This will include monitoring each well for three additional years to confirm that GWPS have been achieved, in accordance 35 I.A.C. § 845.680(c).
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification will be prepared and submitted to IEPA, in accordance with 35 I.A.C. § 845.680(e).

2. CORRECTIVE ACTION OVERVIEW

This CAP is based on the tiered assessment and analysis of alternative remedial technologies and remedies that were completed via the CMA and CAAA (**Appendix A**). The objective of these assessments was to determine the optimal alternative for the PAP that, when coupled with the source control proposed in the Final Closure Plan [4, 5, 6], would remediate groundwater and provide compliance with the GWPS specified under 35 I.A.C. § 845.600.

2.1 Integration of Corrective Action with Source Control (Final Closure)

All documents, assessments, and analyses performed as part of this CAP assume that the source control presented in the Final Closure Plan [5, 6] for the PAP will also be implemented. Source control is the primary corrective action for the PAP and will consist of removing free liquids from the CCR and completing CIP with a consolidate-and-cap approach. This is estimated to include moving a total of 3.6 million cubic yards of CCR within PAP and materials from the Newton Landfill 2 and coal pile may also be moved and utilized as subgrade fill in the PAP closure area. This will result in reducing the final footprint of the PAP from 404 to 252.3 acres. When source control is completed, the remaining CCR in the PAP will be fully encapsulated on all sides by underlying native soils, low-permeability embankment dikes, and a low-permeability final cover system.

Source control alone, without other supplemental corrective action, has been estimated via groundwater modeling to reduce the infiltration of liquids into the PAP by 99 percent (%) relative to pre-closure conditions. Groundwater modeling performed to support the Final Closure Plan estimates that source control activities are expected to result in GWPS being achieved approximately 34 years after closure completion, without implementing other forms of corrective action [8].

The remedy presented in this CAP is supplemental to the removal of free liquids, completion of source control via closure, and placing the CCR above the groundwater table and UA, which when combined, are the primary remedial action that will be performed at the site.

2.2 Corrective Measures Assessment

The CMA [11] was performed for the PAP and submitted to the IEPA on April 3, 2024, after the exceedances[1] of the GWPS were identified. The CMA considered a total of 4 corrective measures for the PAP, including:

- Source Control with Groundwater Polishing (GWP)
- Source Control with Groundwater Extraction (GWE)
- Source Control with Groundwater Cutoff Wall
- Source Control with In-Situ Chemical Treatment

Based on the CMA, three corrective measures, including Source Control-GWP, Source Control-GWE, and Source Control – cutoff wall were identified as potentially viable corrective measures

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of IPGC's operating permit application for the NPP PAP. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, IPGC has not identified any actual exceedances.

for the PAP and were included for further evaluation, design advancement, and comparative assessment within the CAAA for the PAP. The other corrective measures were determined by the CMA to unlikely be viable for the PAP and were not evaluated further within the CAAA.

2.3 Analysis of Corrective Action Alternatives

2.3.1 Corrective Action Alternatives Analysis Supporting Information Report

The CAAA for the PAP was prepared by Gradient based on a Corrective Action Alternatives Analysis Supporting Information Report (CAAA-SIR) prepared by Ramboll. The CAAA-SIR, which is included as Attachment B of the CAAA provided in **Appendix A**, included additional evaluation, design advancement, and comparative assessment of the Source Control-GWP, Source Control-GWE, and Source Control – cutoff wall corrective measures identified as potentially viable for the PAP by the CMA.

The CAAA-SIR evaluation included the completion of feasibility-level design activities for each alternative; this incorporated the following tasks:

- Performing predictive groundwater modeling to evaluate the scope (*i.e.,* location and extents) of each alternative and the corresponding estimated time to achieve GWPS. Following groundwater modeling, Source Control – cutoff wall did not provide any advantages over Source Control – GWP or Source Control – GWE and was not carried any further within the CAAA - SIR;
- Developing feasibility-level design drawings showing the extents in plan and elevation view of each engineered remedy;
- Estimating the time required to design, construct, and implement each remedy, in addition to ongoing operational and maintenance requirements;
- Developing conceptual plans for the storage, treatment, and discharge of extracted groundwater for applicable remedies;
- Identifying future tasks required to implement each alternative, including permitting, investigation, and design efforts; and
- Estimating relevant material quantities, labor hours, delivery miles, equipment miles, and daily commuting miles associated with constructing each remedy.

2.3.2 Corrective Action Alternatives Analysis

The CAAA (**Appendix A**) included a detailed analysis of each of the corrective action alternatives presented in the CAAA-SIR, including an evaluation of:

- Long and short-term effectiveness and protectiveness;
- Ease or difficulty of implementation;
- Degree to which community concerns are addressed; and,
- Relative amount of contamination removed from the environment.

Based on the CAAA, Source Control-GWP was identified as the most appropriate corrective action for the PAP and was selected for further design development as part of this CAP.

3. CORRECTIVE ACTION PLAN

The 35 I.A.C. § 845 requirements for the CAP and corresponding demonstrations that the proposed corrective measures meet these requirements are discussed individually in this section. Many of the CAP requirements are discussed within the CMA and CAAA documents that have been prepared to support the CAP. Therefore, the demonstrations will also refer to those documents.

3.1 General Requirements

35 I.A.C. § 845.670(c): The corrective action plan must meet the following requirements:

(1) Be based on the results of the corrective measures assessment conducted under 35 I.A.C. § 845.660;

(2) Identify a selected remedy that, at a minimum, meets the standards listed in subsection (d);

(3) Contain the corrective action alternatives analysis specified in subsection (e); and

(4) Contain proposed schedules for implementation, including an analysis of the factors in subsection (f).

This CAP is based on the results of the CMA and CAAA, which are included within **Appendix A**. The proposed schedule for implementing the selected Source Control-GWP remedy is provided in **Table 1**.

3.2 Remedy Selection

35 I.A.C. § 845.670(d): The selected remedy in the corrective action plan must:

(1) Be protective of human health and the environment;

Current conditions at the PAP pose no risk to human health or environment. There are also no unacceptable risks to human health and the environment under future conditions. Concentrations of CCR-derived constituents in groundwater are anticipated to decline over time once the PAP is closed and the GWP remedy is in place as presented in the CAAA (**Appendix A)** [12].

(2) Attain the groundwater protection standards specified in 35 I.A.C. § 845.600;

Groundwater modeling indicates Source Control-GWP remedy (Appendix B of the CAAA-SIR which is attached in **Appendix A**), which is selected as the remedy of this CAP, will result in attainment of the GWPS within the current monitoring system within 34 years of final closure completion.

(3) Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in 35 I.A.C. § 845.600 into the environment;

The PAP will be closed using a consolidate-and-cap approach which will act as the main control mechanism to prevent further releases of CCR-derived constituents. If the remedy is found to be unsuccessful in meeting remediation goals, adaptive site management actions will be taken as described within the Corrective Action GMP (**Appendix B**).

(4) Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, taking into account factors such as avoiding inappropriate disturbance of sensitive ecosystems; and

No known releases of CCR due to a structural integrity issue have occurred at the PAP.

(5) Comply with standards for management of wastes as specified in 35 I.A.C. § 845.680(d).

The CCR managed as part of the closure will be done in accordance with all 35 I.A.C. § 845 requirements and the submitted closure plan [5, 6].

3.3 Schedule for Implementation

As presented in Section 4.1 of the CMA and in **Section 1.4.1.1** of this CAP, source control is the most effective means of ensuring the timely attainment of remediation objectives [9]. With groundwater from the PAP impoundment and potential groundwater contributions to surface water posing no unacceptable risks to human health or the environment [12], groundwater polishing is an appropriate "polishing step" provided the corrective action is managed within a reasonable timeframe.

The Source Control-GWP remedy will successfully attain GWPS in a reasonable time[2] as discussed in the following subsections. Timeframes to attain GWPS in the groundwater monitoring wells summarized in **Table A** indicate that 60% of progress is expected to occur within the first five years.

Table A. Estimated Timeframes to Attain GWPS in Groundwater Monitoring Wells

Scenario	Percentage of Wells Predicted to Attain the GWPS				
	1 year**	5 years**	10 years**	33 years**	34 years**
Baseline (CIP) Source Control – GWP	40 %	60 %	60 %	80 %	100 %

*: 5 wells were used to estimate time to reach GWPS in the 2025 Groundwater Modeling Technical Memorandum.
**: Years counted starting from completion of source control.

35 I.A.C. § 845.670(f): The owner or operator must specify, as part of the corrective action plan, a schedule for implementing, of and completing, remedial activities. The schedule must require the completion of remedial activities within a reasonable time, taking into consideration the factors in this subsection (f). The owner or operator of the CCR surface impoundment must consider the following factors in determining the schedule of remedial activities:

The schedule for implementing and completing the Source Control-GWP remedy at the PAP is included in **Table 1**.

The schedule was developed considering the factors required by 35 I.A.C. §§ 845.670(f)(1) through (5), as summarized below.

35 I.A.C. § 845.670(f)(1): Extent and nature of contamination, as determined by the characterization required under 35 I.A.C. § 845.650(d);

The Nature and Extent Report [13], which was submitted to the IEPA on April 3, 2024 and is included with relevant updates as Appendix D to the CAAA report (**Appendix A**). Groundwater

[2] Groundwater Modeling Technical Memorandum is an appendix to CAAA-SIR which is attached to CAAA, **Appendix A** of this CAP.

modeling and geochemical analysis were performed by Ramboll as part of the CAAA-SIR and the modeling considered the nature and extent of contamination.

35 I.A.C. § 845.670(f)(2): Reasonable probabilities of remedial technologies achieving compliance with the GWPS established by 35 I.A.C. § 845.600 and other objectives of the remedy;

Several remedies were evaluated in the CAAA (**Appendix A**) and it was determined that the selected remedy (Source Control–GWP) is expected to achieve compliance with 35 I.A.C. § 845.600 in a reasonable timeframe. The potential for remedial technologies to achieve compliance with the GWPS was evaluated using groundwater modeling [14]. For the selected remedy, the results indicate that groundwater will achieve compliance with the GWPS approximately 34 years after completion of source control, which is described in **Section 1.4.1**. Further, the groundwater modeling indicates flux into and out of the PAP will be reduced by approximately 99%, suggesting a high probability of successful source control [8].

As discussed in the CMA, source control via consolidate-and-cap approach is a proven method for addressing groundwater contamination [11]. The proposed consolidate-and-cap approach is consistent with the requirements of 40 CFR § 257 and 35 I.A.C. § 845. The proposed cover has been demonstrated to be compliant by equivalency in the Final Closure Plan [6] .

Groundwater polishing processes include both physical and chemical mechanisms within the groundwater which reduce the concentrations of COCs in the groundwater. Physical components of groundwater polishing are described by groundwater flow and transport modeling [14]. The contribution of chemical mechanisms to groundwater polishing under current conditions and after source control implementation are evaluated using a geochemical modeling-based approach [15]. When combined with source control, groundwater polishing processes will achieve the GWPS in a reasonable timeframe.

35 I.A.C. § 845.670(f)(3): Availability of treatment or disposal capacity for CCR managed during implementation of the remedy;

The selected remedy includes source control followed by GWP. The CCR will be managed within the footprint of the existing CCR Unit as proposed in the CP for final closure [4, 5, 6]. GWP is not expected to result in the management of an appreciable volume of CCR. Therefore, the treatment and disposal capacity of CCR is not an applicable consideration for the selected remedy.

35 I.A.C. § 845.670(f)(4): Potential risks to human health and the environment from exposure to contamination before completion of the remedy;

A Human Health and Ecological Risk Assessment was completed and included as an attachment to the CAAA (**Appendix A**) that considers the potential risks to human health and the environment before completion of the remedy. The Human Health and Ecological Risk Assessment concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment. This conclusion was reached using methodology consistent with applicable USEPA risk assessment principles. The assessment relied on conservative assumptions meant to overestimate possible exposures and risks and provide an additional level of certainty in the conclusions [12].

35 I.A.C. § 845.670(f)(5): Resource value of the aquifer, including:

The resource value of the aquifer is discussed in the Hydrogeologic Site Characterization Report (HCR), which is included as Attachment B in the CP application for final closure. The uppermost aquifer includes saturated portions of the Mulberry Grove Member in the vicinity of the PAP. Per 35 I.A.C. § 620.210, groundwater within the uppermost aquifer at the PAP meets the definition of Class I – Potable Resource Groundwater. Discontinuous sand lenses of the Hagarstown Member present within the soils overlying the uppermost aquifer have been identified as a potential migration pathway between the PAP and the uppermost aquifer. This information was also considered in the CAAA as part of the Human Health and Ecological Risk Assessment which concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment.

Source Control followed by GWP will result in decline of concentrations of CCR-derived constituents in the uppermost aquifer and potential migration pathways. Off-site migration of CCR-derived constituents is not expected to occur. Groundwater polishing and adaptive site management following Source Control will function until the GWPS is achieved in accordance with the corrective action GMP (**Appendix B**). Paragraphs (A) through (F) from 35 I.A.C. § 845.670(f)(5) are further addressed, as summarized below.

35 I.A.C. § 845.670(f)(5)(A): Current and future uses, including potential residential, agricultural, commercial industrial and ecological uses; and

Current uses and users of the groundwater are discussed in the HCR, Section 5.1 and attachments; and, were considered in the CAAA as part of the Human Health and Ecological Risk Assessment which concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment. Exceedances of the GWPS will remain within the property boundary which is controlled by IPGC. No changes in future residential, commercial or ecological use of the aquifer are expected. In the absence of changes to current and future uses there is no applicable scheduling consideration.

35 I.A.C. § 845.670(f)(5)(B): Proximity and withdrawal rate of users;

A water well inventory was completed in 2021 utilizing federal and state databases to assess nearby pumping wells, drinking water receptors, and other uses of water in the vicinity of the PAP. A search of the Illinois State Geological Survey (ISGS) Illinois Water and Related Wells (ILWATER) Map identified two wells located within 1,000-meters of the PAP (Well Nos. 120790038600 and 120790043600). Both wells are located to the southeast, or side-gradient, of the PAP and are listed as dry and abandoned. The assessment concluded there are no existing off-site water wells, potable or non-potable, that could potentially be impacted by groundwater from the PAP. This information was also considered in the CAAA as part of the Human Health and Ecological Risk Assessment which concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment. In the absence of changes in current and future aquifer uses, there is no applicable scheduling consideration for proximity and withdrawal rates of users.

35 I.A.C. § 845.670(f)(5)(C): Groundwater quantity and quality;

Per 35 I.A.C. § 620.210, groundwater within the uppermost aquifer at the PAP meets the definition of Class I – Potable Resource Groundwater [16]. The Human Health and Ecological Risk Assessment (Appendix A in CAAA) concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment. The selected remedy includes source control followed by GWP. GWP does not include the management of any volume of groundwater. In the absence of groundwater management there is no applicable scheduling consideration pertaining to the quantity and quality of groundwater.

35 I.A.C. § 845.670(f)(5)(D): The potential impact to the subsurface ecosystem, wildlife, other natural resources, crops, vegetation, and physical structures caused by exposure to CCR constituents;

Potential surface receptors are discussed in the HCR Sections 5.2 and 5.3. A survey to identify surface water features, nature preserves, and historic sites was conducted for a 1,000-meter radius around the PAP. Section 3.5 of the Human Health and Ecological Risk Assessment included as Appendix A of the CAAA and CMA/CAAA Report discusses the ecological risk evaluation.

1. Ecological receptors exposed to surface water include aquatic and marsh plants, amphibians, reptiles, and fish. The risk evaluation showed that none of the Constituents of Interest (COIs) in surface water exceeded protective screening benchmarks.
2. Ecological receptors exposed to sediment include benthic invertebrates. The modeled sediment COIs did not exceed the conservative screening benchmarks, therefore, none of the COIs evaluated in sediment are expected to pose an unacceptable risk to ecological receptors.
3. Ecological receptors were also evaluated for exposure to bioaccumulative COIs. This evaluation considered higher trophic-level wildlife with direct exposure to surface water and sediment and secondary exposure through the consumption of dietary items (*e.g.,* plants, invertebrates, small mammals, fish). Mercury was the only ecological COI identified as having potential bioaccumulative effects. However, the modeled concentrations did not exceed benchmarks protective of bioaccumulative effects. Therefore, mercury is not considered to pose an ecological risk *via* bioaccumulation. Overall, this evaluation demonstrated that none of the COIs evaluated are expected to pose an unacceptable risk to ecological receptors.

Overall, this evaluation demonstrated that none of the COIs evaluated are expected to pose an unacceptable risk to ecological receptors. The selected remedy will reduce the concentrations of COI in groundwater. In the absence of unacceptable risks to ecological receptors there is no applicable scheduling consideration.

35 I.A.C. § 845.670(f)(5)(E): The hydrogeologic characteristic of the facility and surrounding land; and

In addition to the CCR present in the PAP, five hydrostratigraphic units have been identified at the PAP based on stratigraphic relationships, geologic composition, and common hydrogeologic properties. The units, listed from surface downward, are summarized as follows:

- **Upper Drift (UD)/Potential Migration Pathway (PMP):** The UD is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.,* PMP).

  - **Hagarstown Member/PMP:** The Hagarstown Member consists of discontinuous sandier deposits of the UD, where present, and overlies the Vandalia Till.
- **Upper Confining Unit (UCU):** This unit consists of the low permeability clay and silt of the Vandalia Till Member (Vandalia Till).
- **Uppermost Aquifer (UA):** This unit is composed of the Mulberry Grove Formation, which has been classified onsite as poorly graded sand, silty sand, clayey sand, and gravel.
- **Lower Confining Unit (LCU):** This unit is comprised of low permeability silt and clay of the Smithboro Till Member (Smithboro Till) and the Banner Formation.
- **Bedrock Unit:** Shale bedrock of the Pennsylvanian-age Mattoon Formation [17] was encountered at the NPP during recent and historical investigations. Based on boring logs, the bedrock surface elevation at the NPP ranges from 408 feet (B141) to 445 feet (APW13) [18]. The locations of these wells and measured bedrock elevations indicate the bedrock surface is highest in the southeast portion of the site and slopes downward to the west and north beneath the PAP.

The effects of these hydrostratigraphic units on schedule were considered by incorporating the geometry, hydraulic, and geochemical properties of these units into the groundwater modeling and groundwater polishing reports, attached to the CAAA-SIR and CAAA, respectively, included in **Appendix A**, which estimate the time to reach the GWPS for remedial alternatives.

35 I.A.C. § 845.670(f)(5)(F): The availability of alternative water supplies.

As discussed in subsection A, there are two potable water wells within 1,000 meters of the PAP [16]. There is currently no need for an alternative water supply well as there are no current unacceptable risks to human or ecological receptors at the site. There are no applicable schedule concerns regarding the availability of alternative water supplies.

3.3.1 Other Relevant Factors

35 I.A.C. § 845.670(f)(6): Other relevant factors.

No additional factors were identified for consideration.

3.4 Necessity of Interim Measures

Source control using the consolidate-and-cap approach is projected to be complete within four to six years after approval of the final closure CP application [4, 5, 6]. 35 I.A.C § 845.680(a)(3) states the owner or operator must take any interim measures necessary to reduce the contaminants leaching from the CCR surface impoundment, and/or potential exposures to human or ecological receptors. Upon completion of source control, the PAP will immediately transition to GWP, therefore no interim measures are required. Further, all subsections of this requirement are discussed as follows.

35 I.A.C. § 845.680(a)(3)(A): Time required to develop and implement a final remedy.

Source control and GWP will be completed in accordance with the schedule provided in **Table 1**. The GWPS will be achieved within a reasonable time frame.

35 I.A.C. § 845.680(a)(3)(B): Actual or potential exposure of nearby populations or environmental receptors to any of the constituents listed in 35 I.A.C. § 845.600.

There are no current unacceptable risks to human or ecological receptors at the site [12]. It was concluded that shallow groundwater and surface water are not a source of drinking water [12]. As there are no current conditions that present a risk to human health or the environment, there will also be no unacceptable risk to human health or the environment for future conditions [12].

35 I.A.C. § 845.680(a)(3)(C): Actual or potential contamination of sensitive ecosystems or current or potential drinking water supplies.

The nature and extent of exceedances have been evaluated in the Nature and Extent Report [13]. Although there are exceedances of GWPS, there are no impacts to current or potential drinking water supplies. As stated above, there are no current unacceptable risks to human or ecological receptors at the site. Additionally, an ecological risk assessment was completed and no unacceptable risks were identified for ecological receptors exposed to surface water and sediment [12]. No potential groundwater receptors are in the vicinity of the PAP [12] and therefore no benefits are anticipated from implementation of an interim measure.

35 I.A.C. § 845.680(a)(3)(D): Further degradation of the groundwater that may occur if remedial action is not initiated expeditiously.

The selected remedy of source control and GWP will achieve the GWPS in a reasonable time frame and no current unacceptable risks to human health or the environment have been identified. No interim measure is expected to prevent further degradation of the groundwater more expeditiously than implementation of the selected remedy.

35 I.A.C. § 845.680(a)(3)(E): Weather conditions that may cause any of the constituents listed in 35 I.A.C. § 845.600 to migrate or be released.

As stated above, the selected remedy of source control and GWP will achieve the GWPS in a reasonable timeframe and no current unacceptable risks to human health or the environment have been identified. No interim measure is expected to further prevent migration of constituents more expeditiously than implementation of the selected remedy.

35 I.A.C. § 845.680(a)(3)(F): Potential for exposure to any of the constituents listed in 35 I.A.C. § 845.600 as a result of accident or failure of a container or handling system.

As stated above, GWP will be implemented immediately after Source Control is completed. As PAP is closed-in-place within a consolidated footprint, no container or handling system will be in use.

35 I.A.C. § 845.680(a)(3)(G): *Other situations that may pose threats to human health and the environment.*

No other situations have been identified where PAP CCR leachate poses threats to human health and environment.

TABLES

Table 1. Proposed Milestone Schedule for Implementing Corrective Action Remedy (Source Control-Groundwater Polishing)

Corrective Action Plan
Newton Power Plant
Primary Ash Pond
Newton, IL

Milestone		Timeframe (Preliminary Estimates)
Pre-Implementation	Corrective Action Plan Submittal	April 2025
	Revised Final Closure Plan Submittal	April 2025
Source Control Construction	Source Control (Closure) Construction • Complete implementation of Source Control	4 to 6 years (*after approval of Revised Final Closure Plan and All Other Closure-Related Permits*)
	Timeframe to Complete Source Control Construction[1]	**4 to 6 years** (*after receipt of all permits required for closure*)
Corrective Action Implementation	Corrective Action Operations and Maintenance • Perform groundwater monitoring and reporting per Corrective Action Groundwater Monitoring Plan	34 years (*after completion of Source Control*[2])
	Corrective Action Groundwater Confirmation Monitoring • Perform groundwater monitoring to demonstrate compliance with GWPS for 3 years, per 35 I.A.C. § 845.680(c)	3 years (*after Corrective Action Operations and Maintenance*)
	Corrective Action Completion • Prepare Corrective Action Completion Report, per 35 I.A.C. § 845.680(E)	3 to 6 months (*after Corrective Action Confirmation Monitoring*)
	Timeframe to Complete Corrective Action[1]	**38 years** (*after completion of Source Control*)

Notes:

[1]All timeframes are preliminary and may change as the project develops. Timeframes may also be affected by regulatory review and/or permit approval processes, for both 35 I.A.C. § 845 and non-35 I.A.C. § 845 permits.

[2] See Table A in Section 3.3 of the report, 50% of progress toward meeting the GWPS is expected to occur within the first two years

GWPS = Groundwater Protection Standard

Summary of Findings

Title 35, Part 845 of the Illinois Administrative Code (IAC) (IEPA, 2021) requires that a Corrective Action Alternatives Analysis (CAAA) be performed as part of the remedy selection, prior to undertaking any corrective actions at certain coal combustion residual (CCR)-containing impoundments, where exceedances of groundwater protection standards (GWPSs) have been identified. This report presents a CAAA for the Primary Ash Pond (PAP) at the Newton Power Plant (NPP), pursuant to the requirements under IAC Section 845.670. The goal of performing a CAAA is to holistically evaluate the potentially viable corrective actions identified in the Corrective Measures Assessment (CMA) (Appendix C; Ramboll, 2024a) in order to remediate groundwater and achieve compliance with the GWPSs specified under IAC Section 845.600 (IEPA, 2021). These analyses assess potentially viable corrective action alternatives based on a wide range of factors, including the efficiency, reliability, and ease of implementation of a corrective action; its potential positive and negative short- and long-term impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021).

It is important to note that many CCR sites are complex groundwater environments where remedial actions will inherently take many years to complete. While no formal definition of a complex groundwater environment exists, most would agree that there are a number of common characteristics at complex groundwater sites, including the following (National Research Council, 2013):

- Highly heterogeneous subsurface environments;
- Large source zones;
- Multiple, recalcitrant constituents; and
- Long timeframes over which releases occurred.

Each of these characteristics are common at CCR sites. Surface impoundments are often tens to hundreds of acres in size and many have operated for decades, leading to large source zones and prolonged releases. Furthermore, CCR impoundments are often located in alluvial geologic settings where sands are interbedded with silts and clays. This results in a heterogeneous environment where constituent mass may persist for many years in low-permeability deposits. Finally, the constituents that are most common at CCR sites include metals and inorganics that do not naturally biodegrade. The combination of these factors results in a complex groundwater environment where remediation, even under the best of circumstances, may take many years to achieve GWPSs. It is for these reasons that the United States Environmental Protection Agency (US EPA) refused to specify what is a reasonable *vs.* an unreasonable timeframe for groundwater corrective actions at CCR sites, stating that it "was truly unable to establish an outer limit on the necessary timeframes—including even a presumptive outer bound" (US EPA, 2015a).

In this CAAA, all corrective actions that have been evaluated consist of source control and residual plume management. Source control is generally considered to be one of the more effective remedial action approaches. Source control involves removing the hydraulic head from an impoundment (*i.e.*, unwatering and dewatering) and preventing further downward migration of constituents. US EPA has found that "releases from surface impoundments [to groundwater] drop dramatically after closure" (US EPA, 2014). US EPA has also stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (US EPA, 2015b). As a result, the implementation of source control often has a substantial and immediate effect on groundwater quality improvements.

The specific source control method that is the central component of all the corrective active alternatives evaluated in this CAAA is closure-in-place (CIP) using a consolidation-and-cap approach. Specifically, this includes the removal of free liquids, excavation and consolidation of CCR from the south, central, and north-central portions of the PAP into the west and east portions, and installation of a low-permeability geomembrane final cover system. These activities are designed to control, minimize or eliminate, post closure infiltration of liquids into the impounded CCR. Excavation and consolidation would result in CCRs being separated vertically, by up to 12 feet (ft), from underlying groundwater during post-closure conditions. As an additional consideration, the PAP is located on a relatively thick layer of low-permeability clay, and the final cover system will tie into the surrounding grades; this closure will result in the isolation of the CCR remaining in the PAP from the surrounding environment, including stormwater, surface water, groundwater,[1] and the atmosphere (HDR, Inc., 2025). The final cover system consists of a 40-milliliter (mil) linear low-density polyethylene (LLDPE) geomembrane layer, a geocomposite drainage layer, and 24 inches (in) of protective soil cover. These measures (consolidation of CCR and installation of a geomembrane cover) will control to the maximum extent feasible, the migration of CCR constituents to groundwater, thus facilitating the achievement of the GWPSs in accordance with IAC Section 845.600. As demonstrated by the groundwater modeling in support of the Closure Alternatives Analysis (CAA) (Gradient, 2022a, 2025), this source control approach would result in a reduction of the migration of water into the PAP by 99% compared to pre-closure conditions. Additionally, source control would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a), demonstrating that source control will control, minimize or eliminate post-closure release of leachate.

Two potential corrective actions are evaluated in this CAAA: Source Control with Groundwater Polishing (Source Control-GWP) and Source Control with two Groundwater Extraction Trenches (Source Control-GWET). Both corrective actions consist of source control and residual plume management and both alternatives were identified as a viable approach in the CMA (Appendix C; Ramboll, 2024a). The residual plume management portions of the two corrective action alternatives include groundwater polishing (GWP) and groundwater extraction trenches (GWETs).

Under the Source Control-GWP alternative, constituent concentrations in groundwater would be actively monitored to ensure the improvement of downgradient groundwater quality resulting from physical and geochemical attenuation mechanisms. Site-specific evaluations demonstrated that groundwater polishing is appropriate at PAP because site conditions are suitable for the attenuation of constituents *via* adsorption. Under the Source Control-GWET alternative, two groundwater extraction trenches would be constructed along the northeast and southwest edges of the former PAP dike; the trenches would remove impacted groundwater and facilitate the achievement of GWPSs in downgradient groundwater. One extraction trench (*i.e.*, the East Trench) would be approximately 2,000 ft long, 3 ft wide, and extend to a depth of 30 ft below ground surface (bgs); the other trench (*i.e.*, the West Trench) would be approximately 2,500 ft long, 3 ft wide, and extend to a depth of approximately 25 to 35 ft bgs. Groundwater collection pipes would be installed at the bottom of the trenches. The trenches would be backfilled with clean granular fill and capped with compacted clay to reduce surface water infiltration. The collection pipes would drain to sumps spaced throughout the trenches to extract groundwater. Extracted groundwater would be collected and sent to a new on-Site lined settling pond and discharged through either a new or existing outfall managed under the National Pollutant Discharge Elimination System (NPDES) permit for the Site. As part of both corrective action alternatives, an adaptive site management plan would be implemented in order to optimize the selected remedy based on real-time data that are collected.

Table S.1 evaluates both corrective actions alternatives (Source Control-GWP and Source Control-GWET) with regard to each of the factors specified under IAC Section 845.670(d) and IAC Section 845.670(e)

[1] Even though the PAP lacks a base liner and leachate collection system, groundwater monitoring data supports that "leachate has not historically been migrating from the site" due to the presence of the clay beneath the PAP (HDR, Inc., 2025).

(IEPA, 2021). Based on this evaluation and the details provided in Section 2 of this report, the most appropriate corrective action for this Site is Source Control-GWP. While the time to achieve GWPSs as predicted by groundwater modeling (excluding corrective action confirmation monitoring and completion reporting) is similar under both alternatives (34 years under Source Control-GWP *vs*. 33 years under Source Control with-GWET), the expected impacts on workers and the environment under the Source Control-GWP alternative are lower than those under the Source Control-GWET. Thus, Source Control-GWP is the most appropriate corrective action alternative for the PAP.

Table S.1 Comparison of Proposed Corrective Action Alternatives with Respect to Factors Specified in IAC Section 845.670(d) and IAC Section 845.670(e)

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
Magnitude of Reduction of Existing Risks (Section 2.2.1; IAC Section 845.670(e)(1)(A))	Because current conditions do not present a risk to human health or the environment at the Primary Ash Pond (PAP), there will be no unacceptable risk to human health or the environment for future conditions when the unit has been closed and source control/residual plume management has been implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. The magnitude of the reduction of existing risks is the same for the two potential corrective action alternatives, and both corrective action alternatives are equally protective of human health and the environment.	Because current conditions do not present a risk to human health or the environment at the PAP, there will be no unacceptable risk to human health or the environment for future conditions when the unit has been closed and source control/residual plume management has been implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. The magnitude of the reduction of existing risks is the same for the two potential corrective action alternatives, and both corrective action alternatives are equally protective of human health and the environment.
Effectiveness of the Remedy in Controlling the Source (Section 2.2.2; IAC Section 845.670(e)(2))		
Extent to Which Containment Practices Will Reduce Further Releases/Control the Sources of Releases to Reduce or Eliminate, to the Maximum Extent Feasible (IAC Section 845.670(e)(2)(A)/IAC Section 845.670(d)(3))	Both alternatives include source control using closure-in-place (CIP) with a consolidation-and-cap approach (which is the primary remedial measure) and residual plume management. Source control would remove residual water in the PAP and this approach would result in CCR within the unit being physically isolated from the surrounding environment (HDR, Inc., 2025). Modeling results (see the CAA; Gradient, 2022a, 2025) indicate that source control in the PAP would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions. Source control is thus effective at controlling the source. Under Source Control-GWP, physical and geochemical attenuation mechanisms would mitigate impacts to downgradient groundwater quality and control the residual plume (Ramboll, 2024b). If necessary, remedy optimizations would be implemented	Both alternatives include source control using closure-in-place (CIP) with a consolidation-and-cap approach (which is the primary remedial measure) and residual plume management. Source control would remove residual water in the PAP and this approach would result in CCR within the unit being physically isolated from the surrounding environment (HDR, Inc., 2025). Modeling results (see the CAA; Gradient, 2022a, 2025) indicate that source control in the PAP would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions. Source control is thus effective at controlling the source. Under the residual plume management for this alternative, groundwater extraction trenches would remove impacted groundwater and control downgradient migration of impacted groundwater. Physical and geochemical attenuation mechanisms would also

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
	under the adaptive site management program.	help mitigate impacts to downgradient groundwater quality and control the residual plume (Ramboll, 2024b). If necessary, remedy optimizations would be implemented under the adaptive site management program.
Extent to Which Treatment Technologies May Be Used (IAC Section 845.670(e)(2)(B))	Source Control-GWP would rely on physical and geochemical attenuation processes. If necessary, remedy optimizations would be implemented under the adaptive site management program.	For the Source Control-GWET alternative, it would require construction of a new on-Site settling pond to settle solids from extracted groundwater from the extraction trench, prior to discharge *via* an NPDES permitted outfall. Other methods for treating extracted groundwater may be evaluated at later phases of the design. The remedy would also rely on physical and geochemical attenuation processes. If necessary, remedy optimizations would be implemented under the adaptive site management program.
Likelihood of Future Releases of CCR (Section 2.2.3; IAC Section 845.670(e)(1)(B))	Both corrective action alternatives include source control using CIP with a consolidation-and-cap approach. As part of this, a new geomembrane cover system would be installed, which would consist of a 40-mil LLDPE geomembrane layer, a geocomposite drainage layer, and 24 in of protective soil cover. Relative to current conditions, this cover system would increase protection against berm and surface erosion, precipitation infiltration, and other adverse effects (Appendix B; Ramboll, 2025b). There would be minimal risk of accidental CCR releases occurring post-closure under either alternative.	Both corrective action alternatives include source control using CIP with a consolidation-and-cap approach. As part of this, a new geomembrane cover system would be installed, which would consist of a 40-mil LLDPE geomembrane layer, a geocomposite drainage layer, and 24 in of protective soil cover. Relative to current conditions, this cover system would increase protection against berm and surface erosion, precipitation infiltration, and other adverse effects (Appendix B; Ramboll, 2025b). There would be minimal risk of accidental CCR releases occurring post-closure under either alternative.
Type and Degree of Long-Term Management, Including Monitoring, Operation, and Maintenance (Section 2.2.4; IAC Section 845.670(e)(1)(C))	Minimal long-term O&M efforts would be required under Source Control-GWP, because it would not require the installation, operation, or maintenance of any engineered systems or structures other than maintenance of the monitoring wells. Corrective action groundwater monitoring would continue until GWPSs have been achieved. Post-closure care groundwater monitoring would continue for a	Long-term O&M efforts required under Source Control-GWET would include the maintenance of the groundwater collection trench system and discharge of extracted groundwater. Extracted groundwater would be managed and treated by a newly-constructed on-Site settling pond before discharge *via* NPDES permitted Outfall. Corrective action groundwater sampling would continue until GWPSs have been achieved.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
	minimum of 30 years as required by IAC Section 845.780(c). Based on the adaptive site management approach, remedy optimizations (additional methods or techniques) might be implemented to ensure achievement of the GWPSs.	Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section. 845.780(c). Based on the adaptive site management approach, remedy optimizations (additional methods or techniques) might be implemented to ensure achievement of the GWPSs.
Short-Term Risks to the Community or the Environment During Implementation of Remedy (Section 2.2.5; IAC Section 845.670(e)(1)(D))		
Safety Impacts	Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. While appropriate controls would be established to prevent accidents and injuries from occurring, the risks of accidents and injuries occurring during source control would be the same for both corrective action alternatives. These source control risks were evaluated in the closure alternatives analysis (CAA) (Gradient, 2022a, 2025). Overall, no worker accidents or injuries would be expected under the Source Control-GWP alternative because no installation, operation, and maintenance of engineered systems or structures would be required. Similarly, no off-Site impacts on nearby residents would be expected under the Source Control-GWP alternative.	Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. While appropriate controls would be established to prevent accidents and injuries from occurring, the risks of accidents and injuries occurring during source control would be the same for both corrective action alternatives. These source control risks were evaluated in the CAA (Gradient, 2022a, 2025). Overall, considering worker accidents occurring during residual plume management both on- and off-Site, 0.97 worker injuries and 0.014 worker fatalities would be expected under the Source Control-GWET alternative, which is higher than the injuries and fatalities expected under the Source Control-GWP alternative. In total, an estimated 0.24 injuries and 3.6×10^{-3} fatalities would be expected to occur among community members due to off-Site activities under the Source Control-GWET alternative, which is higher than the injuries and fatalities expected under the Source Control-GWP alternative.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
Cross-Media Impacts to Air	Cross-media impacts to air can include air pollutants and GHG emissions, which are proportional to the potential impact of each alternative on other emissions from construction vehicles and equipment. Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both corrective action alternatives. Air impacts occurring during source control would be the same for both corrective action alternatives. Impacts associated with CIP using a consolidation-and-cap approach were evaluated in the CAA (Gradient, 2022a, 2025). Residual plume management for the Source Control-GWP alternative would be expected to have minimal air impacts because it would not require the construction of any engineered systems or structures other than activities required for the corrective action groundwater monitoring phase.	Cross-media impacts to air can include air pollutants and GHG emissions, which are proportional to the potential impact of each alternative on other emissions from construction vehicles and equipment. Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Air impacts occurring during source control would be the same for both corrective action alternatives. Impacts associated with CIP using a consolidation-and-cap approach were evaluated in the CAA (Gradient, 2022a, 2025). Residual plume management for the Source Control-GWET alternative would have greater air impacts than the Source Control-GWP alternative, due to the construction and operation of the extraction trench system.
Cross-Media Impacts to Surface Water and Sediments	Updated groundwater modeling performed in support of the CAA (Gradient, 2022a, 2025) predicted that source control (*i.e.*, CIP using a consolidation-and-cap) would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a). The source control would minimize the amount of water retained within the impoundment and reduce hydraulic flux through the CCR. Due to the reduction in the hydraulic flux out of the PAP, the mass flux out of the PAP would also be controlled or minimized. Under residual plume management for the Source Control-GWP alternative, minimal surface water and sediment impacts would be expected, because it would not require the construction of any engineered systems or structures.	Updated groundwater modeling performed in support of the CAA (Gradient, 2022a, 2025) predicted that source control (*i.e.*, CIP using a consolidation-and-cap) would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a). The source control would minimize the amount of water retained within the impoundment and reduce hydraulic flux through the CCR. Due to the reduction in the hydraulic flux out of the PAP, the mass flux out of the PAP would also be controlled or minimized. Under residual plume management for the Source Control-GWET alternative, groundwater collected by the extraction trench would be treated through the on-Site settling pond and discharged to the Newton Lake *via* an NPDES-permitted outfall. Surface water and sediment

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
		impacts under this alternative would be higher than the Source Control-GWP alternative due to the construction of the extraction trench system. Erosion and sediment runoff may occur due to the close proximity to the wetlands and surface water bodies during construction activities.
Control of Exposure to Any Residual Contamination During Implementation of the Remedy	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. While appropriate controls would be established to prevent exposures of CCR during source control, the risks of CCR exposure during source control would be the same for both corrective action alternatives. Risks to workers arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be minimal under the Source Control-GWP alternative, which would not involve exposure to any soil or groundwater waste streams.	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. While appropriate controls would be established to prevent exposures of CCR during source control, the risks of CCR exposure during source control would be the same for both corrective action alternatives. Risks to workers arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be higher for the Source Control-GWET alternative than for the Source Control-GWP alternative, because Source Control-GWET would involve the production, management, and treatment of extracted groundwater, as well as on-Site disposal of excavated spoils generated during extraction trench construction.
Other Identified Impacts	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, impacts during source control would be the same for both of the corrective action alternatives (see the CAA; Gradient, 2022a, 2025). The energy demands of construction equipment and vehicles associated with residual plume management would be greater under the Source Control-GWET alternative, while the energy demands under the Source Control-GWP would lower be because this alternative would	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, impacts during source control would be the same for both of the corrective action alternatives (see the CAA; Gradient, 2022a, 2025). The energy demands of construction equipment and vehicles associated with residual plume management would be greater under the Source Control-GWET alternative because this alternative would involve construction of the GWET system.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
	not require any significant construction activity. Similarly, traffic and noise impacts associated with residual plume management are expected to be minimal because no installation, operation, and maintenance of engineered systems or structures would be required. There would be no impacts to natural resources and habitat under the Source Control-GWP alternative because no additional construction activities would occur after implementation of source.	Similarly, traffic and noise impacts associated with residual plume management would also be expected to be higher under the Source Control-GWET alternative than the Source Control-GWP alternative, due to the construction activities required to construct the extraction trench and settling pond. Under the Source Control-GWET alternative, there would be some negative impacts to natural resources and habitat, including disturbance of some habitat in the immediate vicinity of these locations by causing alarm and escape behavior in nearby wildlife (*e.g.*, due to noise disturbances), and interruption to sensitive aquatic and wetland species in the Newton Lake and other wetlands due to potential sediment runoff during construction. Construction activities would also generate limited negative impacts on the scenic, or recreational value due noise, obstructions of the view, or restricted access during the construction phase.
Time Until Groundwater Protection Standards Are Achieved (Section 2.2.6; IAC Section 845.670(e)(1)(E))	Updated groundwater modeling performed in support of the CAA (Gradient, 2022a, 2025) concluded that source control (*i.e.*, CIP using a consolidation-and-cap approach) alone would result in a 99% reduction in mass flux from the PAP into the underlying groundwater (Ramboll, 2025a). Additional modeling was conducted to evaluate future groundwater quality in the vicinity of the PAP under each of the proposed source control corrective action alternatives. The results indicate that groundwater would attain the GWPSs for all constituents identified as having potential exceedances in the existing PAP monitoring well system within 34 years under the Source Control-GWP alternative after the completion of the source control	Groundwater modeling performed in support of the CAA (Gradient, 2022a, 2025) concluded that source control (*i.e.*, CIP using a consolidation-and-cap approach) alone would result in a 99% reduction in mass flux from the PAP into the underlying groundwater (Ramboll, 2025a). Additional modeling was conducted to evaluate future groundwater quality in the vicinity of the PAP under each of the proposed source control corrective action alternatives. The results indicate that groundwater would attain the GWPSs for all constituents identified as having potential exceedances in the existing PAP monitoring well system within 33 years under the Source Control-GWET alternative after the completion of the source control

	remedy (Appendix B; Ramboll, 2025c). In addition, there would be at least 3 years of corrective action confirmation monitoring, and 6 months of post-closure reporting. So, the overall corrective action implementation duration for the Source Control-GWP alternative is approximately 37.5 years after closure (Appendix B, Section 2.2.6).	remedy (Appendix B; Ramboll, 2025c). In addition, there would be at least 3 years of corrective action confirmation monitoring, and 6 months of post-closure reporting. So, the overall corrective action implementation duration for the Source Control-GWET alternative is approximately 36.5 years after closure (Appendix B, Section 2.2.6).
Potential for Exposure of Humans and Environmental Receptors to Remaining Wastes, Considering the Potential Threat to Human Health and the Environment Associated with Excavation, Transportation, Re-disposal, Containment, or Changes in Groundwater Flow (Section 2.2.7; IAC Section 845.670(e)(1)(F))	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives, thus, potential exposures to CCR remaining in the PAP would be the same under both alternatives. Once source control activities have been completed, this corrective action alternative is expected to limit exposure of humans and environmental receptors to CCR remaining in the PAP. Furthermore, as a result of the source control, there would be minimal risks of CCR releases post closure.	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives, thus, potential exposures to CCR remaining in the PAP would be the same under both alternatives. Once source control activities have been completed, this corrective action alternative is expected to limit exposure of humans and environmental receptors to CCR remaining in the PAP. Furthermore, as a result of the source control, there would be minimal risks of CCR releases post closure. Potential risks to workers that come in contact with residual contamination of CCR-related constituents during groundwater extraction and treatment would be managed through the use of rigorous safety protocols and personal protective equipment. Hydrogeological changes would also be expected under the Source Control-GWET alternative, such as lowering the groundwater table in the vicinity of the extraction trench, altering flow patterns in the uppermost aquifer (UA), and causing changes in hydraulic gradients. However, changes to groundwater flow would not be expected to have an effect on the potential for the exposure of humans and environmental receptors to remaining wastes.

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
Long-Term Reliability of the Engineering and Institutional Controls (Section 2.2.8; IAC Section 845.670(e)(1)(G))	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, long-term reliability during source control would be the same for both corrective action alternatives (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWP alternative would be reliable because it is a proven process that relies on physical and geochemical attenuation processes and active monitoring. If necessary, remedy optimizations would be implemented under the adaptive site management program.	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, long-term reliability during source control would be the same for both corrective action alternatives (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWET alternative would be reliable, as long as the extraction trenches and pumps are maintained and operated appropriately, because it is a proven remedy that has been implemented at many sites. If necessary, remedy optimizations would be implemented under the adaptive site management program.
Potential Need for Replacement of the Remedy (Section 2.2.9; IAC Section 845.670(e)(1)(H))	Replacement of the residual plume management remedy under the Source Control-GWP alternative would likely be unnecessary, because this alternative would not require the installation, operation, and maintenance of engineered systems or structures. Adaptive site management strategies would be used to implement remedy optimizations, if necessary, to ensure that remedial goals are achieved.	Replacement of the residual plume management remedy under the Source Control-GWET alternative would likely be unnecessary as long as the extraction trench and treatment system are maintained and serviced appropriately. Adaptive site management strategies would be used to implement remedy optimizations, if necessary, to ensure that remedial goals are achieved.
Degree of Difficulty Associated with Constructing the Remedy (Section 2.3.1; IAC Section 845.670 (e)(3)(A))	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, construction difficulties would be the same for both corrective action alternatives. Difficulties associated with implementing CIP using a consolidate-and-cap approach were evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWP alternative would rely on physical and geochemical attenuation processes and therefore would not pose any significant construction challenges.	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, construction difficulties would be the same for both corrective action alternatives. Difficulties associated with implementing CIP using a consolidate-and-cap approach were evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWET alternative would rely on the extraction trench and settling pond to extraction and treat impacted groundwater, as well as physical and geochemical attenuation processes. Some challenges may occur

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
		during the construction phase, including: ▪ The implementation of the remedy would require specialized contractors and equipment, specifically a one-pass trenching contractor and associated machinery, for trench installation. Additionally, general construction equipment, including excavation and grading machinery, would be required. ▪ Modifications to the PAP dike to establish an earthen work pad would require a detailed geotechnical design. Furthermore, geotechnical monitoring of the embankment would be essential to identify any signs of distress during construction. If distress is observed, construction activities may need to be temporarily halted to assess the cause and implement appropriate mitigation measures. ▪ Quality control (QC) monitoring would be required throughout the construction phase as part of the overall construction QC and quality assurance (QA) program, to ensure the effectiveness of the GWET system. ▪ Additional pre-design investigations may be necessary to confirm the existing hydrogeologic conditions along the proposed trench locations, to ensure the performance of the GWET. ▪ Groundwater monitoring would be conducted using a groundwater monitoring network designed in accordance with IAC Section 845.680(c).
Expected Operational Reliability of the Remedy (Section 2.3.2; IAC Section 845.670 (e)(3)(B))	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, the operational reliability of the remedy would be the same for both corrective	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, the operational reliability of the remedy would be the same for both corrective

	action alternatives. The reliability associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWP alternative would have high operational reliability because this alternative would rely on natural processes and active monitoring. Geochemical modeling results suggest that as groundwater returns to background conditions, solid sorbing phases are expected to be stable (Appendix E; Ramboll, 2024b). Adaptive site management strategies would be used to implement remedy optimizations, if necessary.	action alternatives. The reliability associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWET alternative would have high operational reliability because it is an established technology, as long as the extraction trench system is maintained and operated appropriately. Adaptive site management strategies would be used to implement remedy optimizations, if necessary.
Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies (Section 2.3.3; IAC Section 845.670 (e)(3)(C))	Required coordination, approvals, and permits associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (Gradient, 2022a, 2025). Residual plume management for the Source Control-GWP alternative would require regulatory approval, but no additional permits would be needed.	Required coordination, approvals, and permits associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (Gradient, 2022a, 2025). Residual plume management for the Source Control-GWET alternative would require regulatory approvals. Groundwater extracted from the extraction trenches would require a modified NPDES permit, which would likely require renewals depending on the timeline of corrective action implementation. In addition, permits from IEPA for construction of stormwater controls and BMPs, placement of excavated spoils beneath the PAP final cover system *via* an amendment to the PAP Closure Plan and Construction Permit Application, would be required. A dam safety modification permit for modification of the embankment may be potentially necessary.
Availability of Necessary Equipment and Specialists (Section 2.3.4; IAC Section 845.670 (e)(3)(D))	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, equipment and specialist needs would	Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, equipment and specialist needs would

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
	be the same for source control activities associated with both corrective action alternatives. An assessment of necessary equipment and specialists associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWP alternative would require standard environmental monitoring equipment and groundwater professionals. Specialists such as geologists, hydrogeologists, statisticians (*i.e.*, statistical analysis), and geochemists would be available to collect and evaluate the data.	be the same for source control activities associated with both corrective action alternatives. An assessment of necessary equipment and specialists associated with implementing CIP using a consolidation-and-cap approach was evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Residual plume management under the Source Control-GWET alternative would require specialists throughout its construction and operational period: ▪ Construction of the groundwater extraction system (*i.e.*, the trench and settling pond) would require a specialized contractor, who would most likely need specialized and often custom-built equipment including one-pass construction equipment. Relatively few construction contractors with experience using one-pass equipment are available. Specialists including design engineers, construction managers and contractor staff experienced in trench construction and similar geologic environments will be required as well. Geotechnical specialists would be required to design the earthen work pad and oversee the PAP embankment for signs of distress during the one-pass trench installation. In addition, specialists and equipment may have backlogs from other projects in the area. ▪ Specialists would be needed to maintain the operation of the GWET system. System components such as totalizers, instrumentation, and the extraction and transfer pumps would require routine maintenance. Non-routine maintenance would also necessitate the use of specialists. Specialists and replacement equipment are typically available within 100 to 300 miles of the Site,

Evaluation Factor (Report Section; Part 845 Section)	Source Control-GWP	Source Control-GWET
		but complex equipment like transfer pumps and controllers may have longer lead times for replacement or servicing. ▪ This alternative would necessitate the use of equipment and the expertise of specialists for tasks such as field data collection, groundwater sampling, analysis, and periodic corrective action groundwater monitoring and reporting. Similar to those in the GWP alternative, these activities are already being conducted as part of routine groundwater monitoring in accordance with IAC Section 845.220(c)(4).
Available Capacity and Location of Needed Treatment, Storage, and Disposal Services (Section 2.3.5; IAC Section 845.670 (e)(3)(D))	No treatment, storage, or disposal services would be required under the residual plume management for the Source Control-GWP alternative, as GWP would not generate any significant volume of waste or wastewater.	Residual plume management for the Source Control-GWET alternative would require the construction of the extraction trench system, which would generate spoils during the construction phase, and the waste materials would be used as subgrade fill beneath the PAP final cover system. Extracted groundwater would be treated at an on-Site settling pond, which would need to be sited, designed, constructed, and maintained properly. Discharge from the settling pond would be conveyed to an NPDES permitted outfall.
The Degree to Which Community Concerns Are Addressed by the Remedy (Section 2.4; IAC Section 845.670(e)(4))	The combination of source control (*i.e.*, CIP using a consolidation-and-cap approach) with residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Ramboll, 2025c), thus addressing community concerns. A public meeting was held on February 26, 2025, pursuant to requirements under IAC Section 845.660(d). Questions raised by attendees were addressed at the meeting; a written	The combination of source control (*i.e.*, CIP using a consolidation-and-cap approach) with residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Ramboll, 2025c), thus addressing community concerns. A public meeting was held on February 26, 2025, pursuant to requirements under IAC Section 845.660(d). Questions raised by attendees were answered at the meeting; a written

	summary of the questions and responses was prepared.	summary of the questions and responses was prepared.
Remove from the Environment as Much of the Contaminated Material That Was Released from the CCR Surface Impoundment as Is Feasible, Taking into Account Factors Such as Avoiding Inappropriate Disturbance of Sensitive Ecosystems (Section 2.5; IAC Section 845.670(d)(4))	There have been no documented releases of CCR from the unit. Both potential corrective action alternatives would have primary source control and residual plume management efforts. The source control would include a consolidation-and-cap approach to limit the infiltration of precipitation into the impounded CCR. Additionally, residual plume management under the Source Control-GWP alternative would address impacted groundwater by relying on natural physical and geochemical attenuation processes to reduce the residual concentrations of CCR-related constituents in groundwater. Site-specific evaluations demonstrated that the groundwater polishing is appropriate at the PAP because site conditions are suitable for the attenuation of constituents *via* adsorption, although sorption of lithium is more pronounced compared to sulfate. Geochemical modeling results suggest that as groundwater returns to background conditions, solid sorbing phases are expected to be stable (Appendix E; Ramboll, 2024b). No ecosystems would be disturbed because no construction activities are expected under the Source Control-GWP alternative.	There have been no documented releases of CCR from the unit. Both potential corrective action alternatives would have primary source control and residual plume management efforts. The source control would include a consolidation-and-cap approach to limit the infiltration of precipitation into the impounded CCR. Additionally, residual plume management under the Source Control-GWET alternative would require a GWET system and rely on natural physical and geochemical attenuation processes to reduce the residual concentrations of CCR constituents in groundwater. The construction activities would likely result in some negative impacts to the ecosystem, including disturbance of some existing habitat atop and near the construction areas. Short-term impacts could also occur to sensitive aquatic and wetland species in Newton Lake and other wetlands or surface water bodies (see Section 1.1.3) due to sediment runoff during construction activities.

1 Introduction

1.1 Site Description and History

1.1.1 Site Location and History

Illinois Power Generating Company's (IPGC) Newton Power Plant (NPP) is an electric power generating facility with coal-fired units located approximately seven miles southwest of the City of Newton, Illinois. The facility began operating in approximately 1977 and is currently scheduled to cease coal operations by the end of 2027 (Meeker, 2020; Ramboll, 2021).

1.1.2 CCR Impoundment

The NPP stores and produces coal combustion residuals (CCRs) as part of its operations. The Primary Ash Pond (PAP; Vistra ID No. CCR Unit 501, Illinois Environmental Protection Agency [IEPA] ID No. W0798070001-01, and National Inventory of Dams [NID] ID No. IL50719), which is the only CCR-containing impoundment at this Site, is the subject of this report.

The PAP (shown in Figure 1.1) is a 404-acre unlined surface impoundment constructed in 1977 for the management of bottom ash, fly ash, and other non-CCR waste generated by the facility (Ramboll, 2021). Decanted water from the PAP discharges into the Secondary Pond, a 9.3-acre non-CCR impoundment located immediately south of the PAP (Ramboll, 2021). The Secondary Pond has a capacity of 83.6 acre-ft, which is used to clarify process water, discharges to Newton Lake *via* National Pollutant Discharge Elimination System (NPDES)-permit (No. IL0049191) outfall 001 located at the Secondary Pond (AECOM, 2016; Ramboll, 2021). Currently, the PAP receives bottom ash, fly ash and low volume wastewater from the plant's two coal-fired boilers. The PAP will no longer receive sluiced ash after coal operations cease at the Newton Power Plant. Final closure of the PAP is expected to be completed by 2028 (Appendix B; Ramboll, 2025b; HDR, Inc., 2025).

Figure 1.1 Site Location Map. Adapted from Ramboll (2021).

1.1.3 Surface Water Hydrology

Newton Lake is an approximately 1,650-acre water body that surrounds the PAP to the east, south, and west. It is located within the Weather Creek and Newton Lake Watersheds (Hydrologic Unit Codes [HUCs] 051201140504 and 051201140503, respectively), which lie within the larger Little Wabash River watershed (HUCs 05120114 and 05120115; Tetra Tech, 2008; US EPA, 2018). The southern boundary of the PAP is approximately 250 to 700 ft from the northern shore of Newton Lake (Ramboll, 2021). The Secondary Pond, which receives decanted water from the PAP, is permitted under NPDES permit No. IL0049191 to discharge to Newton Lake (Figure 1.1, Ramboll, 2021). Newton Lake's surface water elevations are stable, as a result of the lake elevation being controlled by a dam to provide cooling water for the NPP (Ramboll, 2021).

Newton Lake (Assessment Unit ID IL_RCR) is listed on the 2018 Illinois Section 303(d) List as being impaired for fish consumption due to mercury. In addition, it is listed as being impaired for aesthetic quality due to Total Suspended Solids (IEPA, 2019; US EPA, 2018). As of 2008, there is a Total Maximum Daily Load (TMDL) in place to address aesthetic quality impairments in Newton Lake due to an excess of Total Phosphorus (Tetra Tech, 2008).

In addition to Newton Lake, another unnamed 13.7-acre lake is located within 1,000 meters (m) (3,281 ft) of the PAP. There are also several unnamed freshwater ponds located within 1,000 m of the PAP that range in size from 0.3 acres to 6.2 acres (Ramboll, 2021).

1.1.4 Hydrogeology

The geology underlying the Site in the vicinity of the PAP consists of several distinct layers (Ramboll, 2021).

- **Upper Drift (UD)/Potential Migration Pathway (PMP):** The UD is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.*, PMP). The Peoria Silt and Sangamon Soil range in thickness from 3 to 46 ft. The Hagarstown Member ranges from 2-6.9 ft thick and consists of the discontinuous, sandier deposits of the UD, where present, and overlies the Vandalia Till.
- **Upper Confining Unit (UCU):** The UCU consists of a thick package of the low permeability clay and silt of the Vandalia Till. This unit is a laterally continuous layer between the base of the CCR unit and the top of the uppermost aquifer.
- **Uppermost Aquifer (UA):** The UA is composed of a 3-17 ft thick Mulberry Grove Member, which has been classified as poorly graded sand, silty sand, clayey sand, and gravel.
- **Lower Confining Unit (LCU):** The LCU is comprised of low permeability silt and clay of the Smithboro Till Member and the Banner Formation.
- **Bedrock Confining Unit (BCU)**: Bedrock was classified as shale of the Mattoon Formation at the Site.

Groundwater migrates downward through the UD/PMP and UCU into the UA. Groundwater in the UA flows from north to south/southwest and converges near a former drainage feature located west of the PAP (Ramboll, 2025a). Groundwater elevations vary seasonally, although generally less than one foot per year (Ramboll, 2021).

Groundwater within the UA in the northern/upgradient area of the PAP has the potential to interact with surface water in Newton Lake, as evidenced by relatively higher groundwater head elevations compared to the Newton Lake water level. Groundwater within the UD/PMP may also interact with surface water in Newton Lake (Ramboll, 2021). In 2021, 28 surface water samples were collected to characterize the water quality in Newton Lake. Surface water samples were analyzed for IAC Section 845.600 parameters (total and dissolved), ferrous and ferric iron, major ions, and monitored natural attenuation parameters (Appendix B, Ramboll, 2025b; Appendix D, Ramboll, 2024c). The Human Health and Ecological Risk Assessment (Appendix A; Gradient, 2022b) concluded that groundwater from the PAP impoundment and potential groundwater contributions to surface water pose no unacceptable risks to human health or the environment.

During groundwater interaction with surface water, CCR-related constituents may partition between sediments and the surface water column. It should be noted that many CCR-related constituents occur naturally in sediments and surface water (and can also arise from other industrial sources). As a result, their

presence in the sediments and/or surface water of Newton Lake does not necessarily signify contributions from the PAP.

1.1.5 Site Vicinity

The NPP Site is located in a predominantly agricultural area. The PAP is located south of the power plant and is bordered by Newton Lake to the south, east and west (Ramboll, 2021). Scenic and recreational areas within a few miles of the Site include the Newton Lake State Fish and Wildlife Area (SFWA) and the Prairie Ridge State Natural Area/Jasper County Prairie Chicken Sanctuary (Ramboll, 2021). The Newton Lake SFWA, which includes Newton Lake and an additional 5,800 surrounding acres of timber, cropland, and open/non-cultivated land, is preserved by Illinois Department of Natural Resources (IDNR) for fishing, hunting, and wildlife management. Approximately 540 acres of the western shoreline are also used for picnicking, hiking, biking, and horseback riding. The northeastern portion of the Newton Lake SFWA is dedicated to the preservation of the Prairie Chicken, a state-endangered species (IDNR, 2022a). The Prairie Ridge State Natural Area/Jasper County Prairie Chicken Sanctuary, which is located east of Newton Lake, consists of several discontinuous tracts of land that are similarly dedicated to the preservation of the prairie chicken (IDNR, 2022b).

Based on a review of the Illinois Department of Natural Resources (IDNR) Historic Preservation Division database and the Illinois State Archaeological Survey database, there are no historic sites located within 1,000 m of the PAP (Ramboll, 2021).

1.2 Part 845 Regulatory Review and Requirements

Title 35, Part 845 of the Illinois Administrative Code (IAC) (IEPA, 2021) requires that a Corrective Action Alternatives Analysis (CAAA) be performed as part of the remedy selection, prior to undertaking any corrective actions at certain CCR-containing impoundments where exceedances of GWPSs have been identified. Because exceedances of GWPSs in groundwater associated with the PAP have been identified for lithium, sulfate and total dissolved solids (TDS)[2] (Appendix D; Ramboll, 2024c), this report presents a CAAA for the PAP pursuant to the requirements under IAC Section 845.670. The goal of a CAAA is to holistically evaluate a range of factors for the various corrective actions being considered at an impoundment, including the efficiency, reliability, and ease of implementation of the corrective action; its potential positive and negative short- and long-term impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021). A CAAA is a decision-making tool that is designed to aid in the selection of a corrective action alternative.

[2] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or Groundwater Protection Standards (GWPS) as described in the proposed groundwater monitoring program which was submitted to IEPA on October 25, 2021 as part of the Illinois Power Generating Company's operating permit application for the PAP (Burns & McDonnell, 2021). That operating permit application, including the proposed groundwater monitoring program, remains under review by IEPA and therefore Illinois Power Generating Company has not identified any actual exceedances.

2 Corrective Action Alternatives Analysis

This section presents the CAAA pursuant to requirements under IAC Section 845.670 (IEPA, 2021). The goal of a CAAA is to fully evaluate proposed viable corrective measures that were identified in the CMA. The CAAA evaluates potential corrective actions with respect to a wide range of factors, including the performance, reliability, and ease of implementation of the corrective action; its potential impacts on human health and the environment; and its ability to address concerns raised by the community (IEPA, 2021).

Per IAC Section 845.670(d) (IEPA, 2021), any corrective actions selected under a Corrective Action Plan must:

1. Be protective of human health and the environment;
2. Attain the groundwater protection standards specified in Section 845.600;
3. Control the sources of releases to reduce or eliminate, to the maximum extent feasible, further releases of constituents listed in Section 845.600 into the environment;
4. Remove from the environment as much of the contaminated material that was released from the CCR surface impoundment as is feasible, considering factors such as avoiding inappropriate disturbance of sensitive ecosystems; and
5. Comply with standards for management of wastes as specified in Section 845.680(d).

At the PAP, a CAAA is required because groundwater monitoring associated with the PAP identified exceedances of the GWPSs. Groundwater monitoring was conducted between 2015 and 2024 (Appendix D; Ramboll, 2024c,d). The groundwater samples collected from groundwater compliance monitoring wells were used to monitor groundwater quality and evaluate compliance with the groundwater quality standards listed in IAC Section 845.600(a). As of the date of this report lithium, sulfate and TDS were identified as constituents/parameters detected in groundwater at a concentration in excess of its GWPS (Appendix D; Ramboll, 2024d).

Two potentially viable corrective actions for the PAP were selected in the CMA for further consideration in this CAAA. The corrective actions alternatives that are considered in this CAAA are Source Control with Groundwater Polishing (Source Control-GWP) and Source Control with two Groundwater Extraction Trenches (Source Control-GWET). Both of these corrective action alternatives are described below in Section 2.1.

2.1 Corrective Action Alternatives Descriptions

For both corrective actions evaluated in this CAAA, source control is the primary remedy. US EPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (US EPA, 2015b). The source control for the PAP consists of CIP using a consolidation-and-cap approach. Specific elements of this approach include (HDR, 2025; Gradient, 2022a, 2025):

- Unwatering and dewatering of the impoundment *via* pumping and the construction of drilled sumps, engineered trenches, and/or horizontal wells. If needed, perimeter drains would be used to pump and lower groundwater level beneath the PAP. Pumped water would be sent to the Secondary

Pond which discharges to Newton Lake *via* an NPDES permitted outfall and is managed in accordance with the NPDES permit for the facility;

- Excavation and consolidation of approximately 1,920,000 cubic yards (CY) of CCR and approximately 1 foot of soil beneath the CCR from the south, central, and north-central portions of the PAP; and relocation of excavated materials into the west and east portions of the PAP. The consolidation will result in reducing the final footprint of the PAP from 404 acres to 261 acres. Existing outflow structures connecting the PAP to the Secondary Pond will also be removed;
- Removal of the berm between the PAP and the Secondary Pond, followed by removal of the Secondary Pond. Post-closure, an area in the southern portion of the PAP would be used as a stormwater management pond;
- Construction of an alternative cover system consisting of a 40-mil LLDPE geomembrane layer, a geocomposite drainage layer, and 24 in of protective soil cover for supporting vegetative growth;
- Installation of stormwater control structures, including: (i) stormwater channels designed to convey stormwater into the new stormwater pond post-closure, and (ii) drainage pipes, channels, and downchutes designed to reduce erosion in places where channels flow from the PAP final cover and lead into the stormwater pond;
- An existing, 12-acre on-Site landfill would also be closed *via* capping.

These source control activities include the removal of free liquids, excavation, and consolidation of CCR, and the installation of a low-permeability geomembrane final cover system. These activities are designed to control, minimize, or eliminate, post closure infiltration of liquids into the impounded CCR. Excavation and consolidation would result in CCRs being separated vertically, by up to 12 ft, from underlying groundwater during the simulated post-closure conditions. As an additional consideration, the PAP is located on a relatively thick layer of low-permeability clay, and the final cover system will tie into the surrounding grades; this closure will result in CCR remaining in the PAP being physically isolated from the surrounding environment, including stormwater, surface water, groundwater[3], and the atmosphere (HDR, Inc., 2025). The final cover system consists of a 40-mil LLDPE geomembrane layer, a geocomposite drainage layer, and 24 in of protective soil cover. These measures (consolidation of CCR and installation of a geomembrane cover) will control to the maximum extent feasible, the migration of CCR constituents to groundwater, thus facilitating the achievement of the GWPSs in accordance with IAC Section 845.600. As demonstrated by the groundwater modeling in support of the Closure Alternatives Analysis (CAA) (Gradient, 2022a, 2025), this source control approach will result in a reduction of the migration of water into the PAP by 99% compared to pre-closure conditions. Additionally, source control will result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a), demonstrating that source control will control, minimize, or eliminate post-closure releases of leachate.

In addition to source control, the corrective actions evaluated in this CAAA include residual plume management. Two potential corrective actions, identified as viable in the CMA, are evaluated in this CAAA for the PAP:

- **Alternative 1:** Source Control with Groundwater Polishing (Source Control-GWP)
- **Alternative 2:** Source Control with Groundwater Extraction Trenches (Source Control-GWET)

[3] Even though the PAP lacks a base liner and leachate collection system, groundwater monitoring data supports that "leachate has not historically been migrating from the site" due to the presence of the clay beneath the PAP (HDR, Inc., 2025).

For both potential corrective action alternatives, adaptive site management strategies would be integrated into residual plume management. This approach ensures the timely incorporation of new Site information throughout the corrective action process in order to optimize the remediation and expedite achievement of the GWPSs. As part of the adaptive site management approach, system performance and residual plume conditions would be monitored throughout the implementation of the selected corrective action. If groundwater concentrations do not respond as expected to the corrective action, the adaptive site management approach would enable prompt adjustments, optimizations, or replacement of the remedy to ensure overall effectiveness.

2.1.1 Alternative 1: Source Control-GWP

The first corrective action alternative is Source Control-GWP. This remedy includes source control (*i.e.*, CIP using a consolidation-and-cap approach) combined with residual plume management based on natural physical and geochemical processes that would reduce groundwater concentrations downgradient of the PAP. Groundwater polishing mechanisms were evaluated using geochemical speciation and reaction models. The primary objective of the geochemical model was to support the evaluation of groundwater polishing as a potential remedy for the Site. The model focused on evaluating the dominant geochemical reactions that may occur at time scales relevant to groundwater flow, including adsorption and mineral dissolution/precipitation reactions *(i.e.*, iron and aluminum hydroxides, carbonates, and some sulfates) (Appendix E; Ramboll 2024b). Model inputs included geochemically reactive solid mineral phases, downgradient groundwater composition, and background groundwater composition derived from site-specific data. Speciation models analyzed the distribution of chemical constituents between solid and aqueous phases, while reaction models assessed how these distributions may shift in response to changing site conditions (US EPA, 2015).

Components of residual plume management for the Source Control-GWP alternative include:

- Groundwater concentrations would be reduced in the downgradient plume as a result of physical and geochemical attenuation processes. Site-specific evaluation demonstrated that the Site conditions are suitable for physical and geochemical processes of inorganic contaminants *via* adsorption, although sorption of lithium is more pronounced compared to sulfate (Ramboll, 2024b). Specifically, chemical attenuation of contaminants is feasible *via* sorption to aquifer solids, such as iron and aluminum hydroxides, as well as kaolinite under current conditions. Geochemical modeling results suggest that as groundwater returns to background conditions, solid sorbing phases are expected to be stable. However, it should be noted that some remobilization of lithium was expected as groundwater returns to background conditions, although the model may over-estimate the mobility of lithium in the dissolved phase, as suggested by the laboratory batch experiments (Ramboll, 2024b).
- Corrective action groundwater monitoring using a groundwater monitoring system designed in accordance with IAC Section 845.680(c), which would be installed within the plume that lies beyond the waste boundary.
- Adaptive site management strategies for this alternative would include geochemical modeling. Groundwater monitoring results would be evaluated and compared to the model-predicted concentrations. In situations in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques would be evaluated, and if viable, incorporated as per IAC Section 845.680(b).
- Corrective action confirmation groundwater sampling would be performed for 3 years after GWPSs have been achieved.

- Following the completion of the corrective action confirmation monitoring period, a report and certification for Corrective Action Completion would be prepared and submitted to IEPA as per IAC Section 845.680(e).

The overall corrective action implementation duration for this alternative is approximately 37.5 years (450 months) after source control has been completed (Appendix B; Ramboll, 2025b), including:

- 34 years (408 months) of corrective action monitoring (*i.e.*, time to meet GWPSs),
- At least 3 years (36 months) of corrective action confirmation monitoring,[4] and
- 6 months associated with post-closure reporting.

Although source control (*i.e.*, control-in-place [CIP]) is a primary component of the corrective action, the labor time, equipment usage, and mileage linked to source control were previously estimated in the Closure Alternative Analysis (CAA) and updated in 2025 based on new CIP plan (Gradient, 2022a, 2025) and are not repeated in this analysis. There is no labor and mileage incurred with the residual plume management under the Source Control and GWP alternative, because no construction would be required under this alternative. Mileage and labor associated with corrective action monitoring was not included in this analysis (Appendix B; Ramboll, 2025b).

2.1.2 Alternative 2: Source Control-GWET

The second corrective action alternative is Source Control-GWET. This remedy includes source control (*i.e.*, CIP using a consolidation-and-cap approach) with groundwater extraction trenches (GWET) as the residual plume management approach. The residual plume management would include the construction of two extraction trenches, the East and the West Trenches, by excavating the trenches to capture impacted groundwater from the UA and PMP. The East Trench would be located along the northeastern perimeter of the CIP portion of the PAP along the exterior toe of the former perimeter dike. It would be about 2,000 ft long, 3 ft wide, and would extend to an elevation of about 503 ft or about 30 ft below ground surface (bgs). The West Trench would be located along the southwestern toe of the former perimeter dike of the excavation portion of the PAP. It would be about 2,500 ft long, 3 ft wide, and extend to an elevation of about 510 ft or about 25-35 ft bgs. Collection pipes would be installed at the bottom of the trenches. The trenches would be backfilled with clean granular fill and capped with compacted clay to reduce surface water infiltration. Groundwater that is captured would be pumped to a new on-Site lined settling pond and discharged through either a new or existing outfall and would be managed in accordance with the NPDES permits for the Site.

Implementation of residual plume management for the Source Control-GWET is expected to include various tasks across three major phases: pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action operations, maintenance, and closeout (Phase 3). The activities associated with each of these phases are summarized below:

- **Phase 1:** Pre-construction activities including obtaining permits from agencies and completing Site investigations and engineering designs.
- **Phase 2:** Construction of the extraction trenches, settling pond, and minor Site restoration of disturbed areas;

[4] It should be noted that post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section. 845.780(c).

- Mobilization of equipment and materials to the Site, and preparation for Site construction;
- The GWETs would be constructed using one-pass trenching methods by excavating subgrade soils, placing collection piping and pumps, and backfilling the trench with clean granular fill;
- Excavated soils would be placed in the PAP as subgrade fill beneath the final cover system;
- The 1-acre, geomembrane-lined settling pond would be constructed to manage extracted groundwater using conventional construction equipment; and
- Site restoration would be completed following the construction of the GWETs and settling pond.

- **Phase 3:** Operations, Maintenance, and Closeout of the GWET system. Details pertaining to each of these activities are outlined below.
  - Operation of the GWET system;
  - Corrective Action O&M would involve routine and non-routine maintenance of extraction pumps, air compressor, and other system components;
  - Monitoring of extracted groundwater under the appropriate modified NPDES permit;
  - Groundwater concentrations would also be reduced in the downgradient plume as a result of physical and geochemical attenuation processes;
  - Adaptive site management strategies would be employed to track remediation progress and incorporate new Site information to assure the achievement of the GWPSs;
  - Corrective action monitoring would be performed using a corrective action groundwater monitoring network designed in accordance with IAC Section 845.680(c), which would be installed within the plume that lies beyond the waste facility boundary;
  - Corrective action confirmation monitoring would be performed for 3 years after GWPSs have been achieved; and
  - Following the completion of the corrective action confirmation monitoring period, a report and certification for Corrective Action Completion would be prepared and submitted to IEPA as per IAC Section 845.680(e).

The overall corrective action implementation duration is approximately 41 to 43 years (489 to 516 months) (Appendix B), including:

- Approximately 3.5 to 5 years (42 to 60 months) of pre-construction activities (Phase 1; assumed to occur concurrently with source control);
- Approximately 9 to 18 months of corrective action construction (Phase 2; assumed to occur concurrently with source control);
- Approximately 36.5 years (438 months) of corrective action operation, maintenance, and closeout (Phase 3) after source control is completed.
  - The duration of Phase 3 is estimated to include 33 years (396 months) of corrective action operations and maintenance (O&M) (*i.e.*, time to meet GWPSs), at least 3 years (36 months) of corrective action confirmation monitoring,[5] and 6 months associated with post-closure reporting.

[5] It should be noted that post-closure care groundwater monitoring would continue for a minimum of 30 years or until such time as GWPSs are achieved, whichever is longer, as required by IAC Section 845.780(c).

Key parameters for the Source Control-GWET corrective action alternative are shown in Table 2.2, below.

Table 2.1 Key Parameters for the Source Control-GWET Corrective Action Alternative[a]

Parameter[b]	Value[c]
Labor Hours	
Total On-Site Labor	41,000 hours
Total Off-Site Labor	0 hours
40% Contingency	16,400 hours
Total Labor Hours:	57,500 hours
Vehicle and Equipment Travel Miles	
Vehicles On-Site	90,000 miles
On-Site Haul Trucks (Unloaded + Loaded)	1,410 miles
Labor Mobilization	875,000 miles
Equipment Mobilization (Unloaded + Loaded)	20,300 miles
Off-Site Haul Trucks (Unloaded + Loaded)	62,500 miles
Material Deliveries (Unloaded + Loaded)	21,600 miles
Total On-Site Vehicle and Equipment Travel Miles:	91,400 miles
Total Off-Site Vehicle and Equipment Travel Miles:	979,000 miles
Total Vehicle and Equipment Travel Miles:	1,070,000 miles

Notes:
Source Control-GWET = Source Control with Groundwater Extraction Trench.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the labor time, equipment usage, and mileage linked to source control were previously estimated in the Closure Alternative Analysis (CAA) and are not repeated in this analysis.
(b) Mileage and labor related to sampling and monitoring is not included for either alternative.
(c) Values reported in this table were rounded to reflect 3 significant figures.
Source: Appendix B.

2.2 Long- and Short-Term Effectiveness and Protectiveness of Corrective Action Alternative (IAC Section 845.670(e)(1))

2.2.1 Magnitude of Reduction of Existing Risks (IAC Section 845.670(e)(1)(A))

There are no current unacceptable risks to human or ecological receptors at this Site associated with the PAP, based on a Human Health and Ecological Risk Assessment performed for the Site (Appendix A; Gradient, 2022b). Because current conditions do not present a risk to human health or the environment at the PAP, there will be no unacceptable risk to human health or the environment for future conditions when the unit has been closed and source control/residual plume management has been implemented. Concentrations of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline. As a result of this, the magnitude of the reduction of existing risks is the same for both potential corrective action alternatives (IAC Section 845.670(e)(1)(A)), and both corrective action alternatives are equally protective of human health and the environment (IAC Section 84.670(d)(1)).

2.2.2 Effectiveness of the Remedy in Controlling the Source (IAC Section 845.670(e)(2)/IAC Section 845.670(d)(3))

Extent to Which Containment Practices Will Reduce Further Releases/Control the Sources of Releases to Reduce or Eliminate, to the Maximum Extent Feasible (IAC Section 845.670(e)(2)(A)/IAC Section 845.670(d)(3))

Source control would be implemented for both corrective action alternatives, which includes removal of free liquids, consolidation of CCR into the northern and eastern portion of the impoundment and the installation of a low-permeability geomembrane cover system designed to limit the infiltration of precipitation into the impounded CCR. This approach would remove water currently retained within the impoundment, which further reduces the hydraulic flux through the CCR (Ramboll, 2025a). Updated groundwater modeling performed in support of the CAA (Gradient, 2022a) and updated CAA (Gradient, 2025) concluded that source control alone would result in a 99% reduction in mass flux from the PAP into the underlying groundwater (Ramboll, 2025a). Because source control would be undertaken at the Site prior to the implementation of any residual plume management, both corrective action alternatives would remove the potential for CCR within the impoundment to impact groundwater. Both corrective action alternatives would therefore be equally and fully protective with regard to source control. The effectiveness of the corrective action alternatives with respect to residual source control are summarized as follows:

- Under the Source Control-GWP alternative, the attenuation of dissolved constituent concentrations remaining after source control would be achieved through natural physical and geochemical processes. Site-specific evaluation demonstrated that Site conditions are suitable for physical and geochemical processes of inorganic contaminants. Specifically, chemical attenuation of contaminants is feasible *via* sorption to aquifer solids, such as iron and aluminum hydroxides, as well as kaolinite under current conditions. The sorption of sulfate was predicted to be stable as groundwater returns to background conditions, while some remobilization of lithium was expected as groundwater returns to background conditions. In cases in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques would be evaluated under the adaptive site management, and if viable, incorporated as per IAC Section 845.680(b).
- Under the Source Control-GWET alternative, residual contamination control would be achieved by extracting impacted groundwater and preventing downgradient migration through installation of two extraction trenches at the east and west portions of the PAP. GWET is a widely used corrective measure that has been effectively implemented at many sites to contain and capture dissolved-phase groundwater plumes. In cases in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques to achieve the GWPSs would be evaluated under the adaptive site management plan, and if viable, incorporated as per IAC Section 845.680(b).

Because both corrective action alternatives include source control and residual plume management, both potential corrective action alternatives would be equally effective at reducing, to the maximum extent feasible, releases from both primary and residual sources (IAC Section 845.670(e)(2)(A)/IAC Section 845.670(d)(3)).

Extent to Which Treatment Technologies May Be Used (IAC Section 845.670(e)(2)(B))

Because Source Control-GWP would rely on physical and geochemical processes, no additional treatment technologies would be required. For the Source Control-GWET alternative, in addition to physical and geochemical processes, a new on-Site settling pond would be constructed to remove solids from extracted groundwater, prior to discharge *via* an NPDES permitted outfall. Other methods for treating extracted groundwater may be evaluated at later phases of the design (Appendix B). For both corrective action alternatives, remedy optimizations would be implemented, if necessary, under the adaptive site management program.

2.2.3 Likelihood of Future Releases of CCR (IAC Section 845.670(e)(1)(B))

Both corrective action alternatives include source control using CIP with a consolidation-and-cap approach. As part of this, a new cover system would be installed over the PAP, which consists of a 40-mil LLDPE geomembrane layer, a geocomposite drainage layer, and 24 in of protective soil cover. Stormwater control features such as stormwater channels, drainage pipes, and downchutes would be installed to route the flow to the stormwater pond. Relative to current conditions, this cover system would provide increased protection against berm and surface erosion, precipitation infiltration, and other adverse effects that could potentially trigger a release of CCR. There would be minimal risk of accidental CCR releases occurring post-closure under both corrective action alternatives.

2.2.4 Type and Degree of Long-Term Management, Including Monitoring, Operation, and Maintenance (IAC Section 845.670(e)(1)(C))

The type and degree of long-term residual groundwater plume management associated with both corrective action alternatives are summarized as follows:

- Residual plume management for the Source Control-GWP alternative would not require the installation, operation, or maintenance of any engineered systems or structures, other than maintenance of the monitoring well network. The only long-term management activity required under this alternative would be corrective action monitoring and routine maintenance of the monitoring wells, which would continue at least 3 years after GWPSs have been achieved for all wells, in accordance with IAC Section 845.680(c)(2). Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by IAC Section 845.780(c). Based on the adaptive site management approach, remedy optimization (additional methods or techniques) may be implemented to ensure the achievement of the GWPSs.
- Residual plume management for the Source Control-GWET would require multiple tasks to be completed over three phases: pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action O&M and closeout (Phase 3). Once pre-construction activities are completed, construction of the extraction trench would occur during the latter stages of the PAP closure. This approach allows for the spoils generated from the extraction trench construction to be disposed beneath the final cover system of the PAP. Corrective action O&M would require regular inspection and maintenance of the extraction trench system. Extracted groundwater would be managed and treated by a newly-constructed on-Site settling pond before discharge *via* a new or existing NPDES outfall to Newton Lake. Additionally, corrective action groundwater sampling and routine maintenance of the monitoring well network would continue for at least 3 years after GWPSs have been achieved at all wells, in accordance with IAC Section 845.680(c)(2). Post-closure care groundwater monitoring would continue for a minimum of 30 years as required by

IAC Section 845.780(c). Based on the adaptive site management approach, remedy optimization (additional methods or techniques) may be implemented to ensure the achievement of the GWPSs.

2.2.5 Short-Term Risks to the Community or the Environment During Implementation of Remedy (IAC Section 845.670(e)(1)(D))

2.2.5.1 Safety Impacts

Best practices would be employed during construction in order to ensure worker safety and comply with all relevant regulations, permit requirements, and safety plans. However, it is impossible to completely eliminate risks to workers during construction and/or other corrective action activities. For example, injuries and fatalities can occur due to truck accidents or equipment malfunctions. Truck accidents that occur off-Site can also result in injuries or fatalities to community members. The safety impacts associated with source control (*i.e.*, CIP using a consolidation-and-cap approach), which were evaluated in the CAA (Gradient, 2022a, 2025), are the same for both corrective action alternatives. The safety impacts associated with residual plume management (*i.e.*, construction, and O&M) for each corrective action alternative are described below.

- The Source Control-GWP alternative would not require the construction of any engineered systems or structures, and therefore no safety impacts are expected.
- The Source Control-GWET alternative would include the construction of groundwater extraction trenches and a settling pond to collect, extract, and treat CCR-impacted groundwater. Potential safety concerns would be related to the construction and O&M of the GWET extraction trench and settling pond.

Worker Risks

On-Site accidents include injuries and deaths arising from the use of heavy equipment and/or earthmoving operations during Site activities. Off-Site accidents include injuries and deaths due to vehicle accidents during labor and equipment mobilization/demobilization, as well as materials/supplies hauling and deliveries.

As discussed in section 2.1.1, there are no construction activities or operational requirements associated with residual plume management for the Source Control-GWP alternative. Ramboll estimates that residual plume management for the Source Control-GWET corrective action alternative would require 41,100 on-Site labor hours associated with construction and operation of the system (Appendix B). The US Bureau of Labor Statistics (US DOL, 2020a,b) provides an estimate of the hourly fatality and injury rates for construction workers. Based on the accident rates reported by the US Bureau of Labor Statistics and the on-Site labor hours reported in Appendix B, we estimate that approximately 0.43 worker injuries and 3.7×10^{-3} worker fatalities would occur on-Site under the Source Control-GWET corrective action alternative (Table 2.2). The number of on-Site worker accidents is therefore expected to be higher under the Source Control-GWET alternative and no worker accidents would be expected under the Source Control-GWP alternative.

Table 2.2 Expected Number of On-Site Worker Accidents Under Each Corrective Action Alternative[a]

Corrective Action Alternative	Injuries	Fatalities
Source Control-GWP	0	0
Source Control-GWET	0.43	3.7×10^{-3}

Notes:
Source Control-GWET = Source Control with Groundwater Extraction Trench; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the worker accidents associated with source control were previously estimated in the Closure Alternative Analysis (CAA) and are not repeated in this analysis.

The Source Control-GWET alternative would result in off-Site hauling, labor and equipment mobilization/demobilization, and material deliveries (Table 2.1). For residual plume management under the Source Control-GWET corrective action alternative, 979,000 total off-Site vehicle and equipment travel miles would be required. In contrast, for residual plume management under the Source Control-GWP alternative, no vehicle and equipment travel miles would be required (Appendix B; Section 2.1.1). The United States Department of Transportation (US DOT) provides estimates of the expected number of fatalities and injuries "per vehicle mile driven" for drivers and passengers of large trucks and passenger vehicles (US DOT, 2023). Table 2.3 shows the expected number of off-Site accidents under each corrective action alternative due to all categories of off-Site vehicle usage. For these calculations, it was assumed that labor mobilization/demobilization would rely upon passenger vehicles (cars or light trucks, including pickups, vans, and sport utility vehicles) and that hauling, equipment mobilization/demobilization, and material deliveries would rely upon large trucks. Based on US DOT's accident statistics and the mileage estimates in Appendix B, 0.54 worker injuries and 0.01 worker fatalities would be expected to occur due to off-Site activities under the Source Control-GWET alternative, while there are no off-Site accidents expected under the Source Control-GWP alternative.

Table 2.3 Expected Number of Off-Site Worker Accidents Related to Off-Site Car and Truck Use Under Each Corrective Action Alternative[a]

Off-Site Vehicle Use Category	Source Control-GWP		Source Control-GWET	
	Injuries	Fatalities	Injuries	Fatalities
Hauling	0	0	0.013	9.9×10^{-4}
Labor Mobilization/Demobilization	0	0	0.52	8.3×10^{-3}
Equipment Mobilization/Demobilization	0	0	4.3×10^{-3}	3.2×10^{-4}
Material Deliveries	0	0	4.6×10^{-3}	3.4×10^{-4}
Total:	0	0	0.54	0.01^{0}

Notes:
Source Control-GWET = Source Control with Groundwater Extraction Trench; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the worker accidents associated with source control were previously estimated in the Closure Alternative Analysis (CAA) and are not repeated in this analysis.

Overall, considering accidents occurring both on- and off-Site, no worker injuries and worker fatalities would be expected to occur for residual plume management under the Source Control-GWP alternative; and 0.97 worker injuries and 0.014 worker fatalities would be expected to occur for residual plume management under the Source Control-GWET alternative. Thus, overall risks to workers would be higher under the Source Control-GWET alternative.

Community Risks

Vehicle accidents that occur off-Site can result in injuries or fatalities among community members as well as workers. Based on the accident statistics reported by US DOT (2023) and the off-Site travel mileages reported in Appendix B (and summarized in Tables 2.1), off-Site vehicle accidents could result in an estimated 0.24 injuries and 3.6×10^{-3} fatalities among community members (*e.g.*, people involved in haul truck accidents that are neither haul truck drivers nor passengers, including pedestrians, drivers of other vehicles, *etc*.) for residual plume management under the Source Control-GWET alternative (Table 2.4). No off-Site risks are expected under the Source Control-GWP alternative. Therefore, off-Site impacts on nearby residents, including injuries or fatalities, would be higher under the Source Control-GWET alternative.

Table 2.4 Expected Number of Community Accidents Under Each Corrective Action Alternative[a]

Off-Site Vehicle Use Category	Source Control-GWP		Source Control-GWET	
	Injuries	Fatalities	Injuries	Fatalities
Hauling	0	0	0.016	1.2×10^{-4}
Labor Mobilization/Demobilization	0	0	0.21	3.4×10^{-3}
Equipment Mobilization/Demobilization	0	0	5.3×10^{-3}	3.9×10^{-5}
Material Deliveries	0	0	5.7×10^{-3}	4.2×10^{-5}
Total:	0	0	0.24	3.6×10^{-3}

Notes:
Source Control-GWET = Source Control with Groundwater Extraction Trench; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Although source control (*i.e.*, closure-in-place [CIP]) is a primary component of the corrective action, the community accidents associated with source control were previously estimated in the Closure Alternative Analysis (CAA) and are not repeated in this analysis.

2.2.5.2 Cross-Media Impacts to Air

Air pollution can occur both on-Site (*e.g.*, construction activities) and off-Site (*e.g.*, along transportation routes), potentially impacting workers as well as community members. Diesel emissions are a major source of air pollutants and GHG emissions at construction sites. Diesel exhaust contains air pollutants, including nitrogen oxides (NO_x), particulate matter (PM), carbon monoxide (CO), and volatile organic compounds (VOCs) (Hesterberg *et al*., 2009; Mauderly and Garshick, 2009). Construction equipment also emits greenhouse gases (GHGs), including carbon dioxide (CO_2) and possibly nitrous oxide (N_2O). The potential impact of each corrective action alternative on GHG emissions is proportional to the potential impact of each alternative on other emissions from construction vehicles and equipment.

Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Air impacts occurring during source control would be the same for both corrective action alternatives. Impacts associated with CIP using a consolidation-and-cap approach were evaluated in the CAA (Gradient, 2022a, 2025). On-Site emissions would be higher for residual plume management under the Source Control-GWET alternative due to the greater amount of on-Site vehicle travel miles required under this corrective action alternative (91,400 total on-Site travel miles under the Source Control-GWET alternative while no on-Site travel miles under the Source Control-GWP alternative; Section 2.1.1 and Tables 2.1). Off-Site emissions would similarly be higher for residual plume management under the Source Control-GWET alternative due to the greater amount of off-Site vehicle and equipment travel miles required under this alternative (979,000 total off-Site travel miles under the Source Control-GWET alternative while no off-Site travel miles under the Source Control-GWP alternative). In summary, air impacts would be higher for the Source Control-GWET alternative than the Source Control-GWP alternative.

2.2.5.3 Cross-Media Impacts to Surface Water and Sediments

Under both action alternatives, the constituent mass flux from groundwater into surface water would decline over time after source control has been completed (Ramboll, 2025a). Source control would include removal of free liquids, consolidation of CCR in the PAP into the northern and eastern portion of the impoundment and the installation of a low-permeability final cover system to limit the precipitation infiltration into the impounded CCR. This approach would minimize the amount of water retained within the impoundment, which further reduces the hydraulic flux through the CCR. As demonstrated by the updated groundwater modeling in support of the Closure Alternatives Analysis (CAA) (Gradient, 2022a, 2025), this source control approach would result in a reduction of the migration of water into the PAP by 99% compared to pre-closure conditions. Additionally, source control would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a). Due to the reduction in the hydraulic flux out of the PAP, the mass flux out of the PAP would also be controlled or minimized.

Under the Source Control-GWP alternative, minimal surface water and sediment impacts would be expected associated with residual plume management because it would not require the construction of any engineered systems or structures (other than utilizing existing monitoring wells).

Under the Source Control-GWET alternative, surface water and sediment impacts would be higher than the Source Control-GWP alternative due to the construction of the extraction trench system. Construction can have short-term negative impacts on surface water and sediment quality immediately adjacent to a site due to erosion and sediment runoff. Any associated impacts would be addressed through best management practice (BMPs) in accordance with Site land disturbance permits.

2.2.5.4 Control of Exposure to Any Residual Contamination During Implementation of the Remedy

Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. While appropriate controls would be established to prevent exposures of CCR during source control, the risks of CCR exposure during source control activities would be the same for both corrective action alternatives. For each of the corrective action components for the two potential alternatives, no residual CCR exposures would be expected to occur. However, impacted soils and groundwater can be a source of CCR-related constituent exposure for workers. Risks to workers arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be higher for the Source Control-GWET than for the Source Control-GWP alternative; the Source Control-GWET would involve the production, management, and treatment of extracted groundwater, as well as on-Site disposal of excavated spoils generated during extraction trench construction. The Source Control-GWP alternative would not involve exposure to either of these soil or groundwater waste streams. Any potential CCR-exposures during the Source Control-GWET alternative would be managed through the use of rigorous safety protocols and personal protective equipment.

2.2.5.5 Other Identified Impacts

Source control (*i.e.*, CIP using a consolidation-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, impacts during source control would be the same for both of the corrective action alternatives (see the CAA; Gradient, 2022a, 2025).

In addition to safety impacts, cross-media impacts, and the potential for workers to be exposed to residual contamination, construction activities and remedial operations can have significant energy demands and can cause nuisance impacts such as traffic and noise. Energy consumption at a construction site is synonymous with fossil fuel consumption because the energy to power construction vehicles and equipment comes from the burning of fossil fuels. Fossil fuel demands considered here include the burning of diesel fuel during construction equipment and vehicle travel miles. Because GHG emission impacts and energy consumption impacts both arise from the same sources at construction sites, the trends discussed in Section 2.2.5.2 with respect to GHG emissions also apply to the evaluation of energy demands. Specifically, the energy demands of construction equipment and vehicles associated with residual plume management would be greater under the Source Control-GWET, while the energy demands under the Source Control-GWP alternative associated with residual plume management are expected to be lower, because the latter alternative would not require any significant construction activity. In addition, energy would be required for the operation of the extraction trench system under the Source Control-GWET alternative; there is no operational energy required under the Source Control-GWP alternative because it would rely on natural attenuation processes.

Similarly, traffic and noise impacts associated with residual plume management are also expected to be higher under the Source Control-GWET alternative than the Source Control-GWP alternative, due to the construction activities required to construct the extraction trench system. Traffic may increase temporarily around the Site under the Source Control-GWET alternative due to the daily arrival and departure of the workforce, equipment mobilization/demobilization, and material deliveries. However, these impacts would be expected to largely occur at the beginning or end of each work day (for the arrival/departure of the work force), at the beginning or end of the construction period (for equipment mobilization/demobilization), and at specific times throughout the construction period (for material deliveries). Traffic and noise impacts associated with residual plume management from the Source Control-GWP alternative is expected to be significantly less than those associated with the Source Control-GWET alternative.

Construction activities can negatively impact natural resources and habitat near the Site, as well as scenic, historical, and recreational value. Based on a review of the Illinois Department of Natural Resources (IDNR) Historic Preservation Division database and the Illinois State Archaeological Survey database, there are no historic sites located within 1,000 m of the PAP (Ramboll, 2021). There would be no impacts under the Source Control-GWP alternative because no additional construction activities would occur after implementation of source control. However, the Source Control-GWET alternative would require construction of extraction trenches and a 1-acre on-Site settling pond, which would occur during the latter phase of the PAP closure construction, and specialty equipment such as one-pass trenching equipment and other supporting equipment would be used. These impacts would include disturbance of some existing habitats in the immediate vicinity of these locations by causing alarm and escape behavior in nearby wildlife (*e.g.*, due to noise disturbances). It is also possible that limited negative short-term impacts could occur to sensitive aquatic and wetland species in Newton Lake and other surface water bodies near PAP (see Section 1.1.3) due to sediment runoff during construction. Construction activities related to the Source Control-GWET alternative would cause some limited negative impacts on the scenic, or recreational value of the areas immediately surrounding the Site due to, *e.g.*, noise, obstructions of the view, or restricted access; however, these impacts are expected to diminish once the construction is completed.

2.2.6 Time Until Groundwater Protection Standards Are Achieved/Attain the Groundwater Protection Standards Specified in Section 845.600 (IAC Section 845.670(e)(1)(E)/IAC Section 845.680(d)(2))

This section of the report evaluates the time required to achieve GWPSs, pursuant to requirements under IAC Section 845.670(e)(1)(E) (IEPA, 2021) and under IAC Section 845.680(d)(2).

Groundwater and dissolved constituents move downward through the UD/PMP and UCU into the UA in the vicinity of the PAP. Groundwater within the UA flows generally from the north towards the south and southwest and converges near a former drainage feature located west of the PAP (Ramboll, 2021). Groundwater elevations in the UA at downgradient of the PAP has been observed approximately 15 ft lower than the Newton Lake elevation, which suggest that groundwater in the UA does not flow into the Lake. However, in the northern/upgradient area of the PAP, groundwater from the UA may interact with surface water in Newton Lake, as evidenced by relatively higher groundwater head elevations compared to the Newton Lake water level. Groundwater within the UD/PMP may also interact with surface water in Newton Lake (Ramboll, 2021).

Groundwater modeling was performed in support of the CAA (Gradient, 2022a, 2025). The modeling predicted that source control (*i.e.*, CIP using a consolidation-and-cap approach) would result in a reduction of the migration of water into the PAP by 99% compared to pre-closure conditions. Additionally, source control would result in a reduction of hydraulic flux out of the PAP by 99% compared to pre-closure conditions (Ramboll, 2025a). Additional modeling was conducted for each of the corrective action alternatives to evaluate future groundwater quality in the vicinity of the PAP as a result of residual plume management (Ramboll, 2025c), and the results of the modeling indicate that groundwater would attain the GWPSs for all of the constituents[6] identified as having potential groundwater exceedances in the existing PAP monitoring well system within approximately 34 and 33 years, under the Source Control-GWP and Source Control-GWET alternatives after the completion of the source control, respectively (Appendix B; Ramboll, 2025c), and thus satisfy the GWPSs criteria in IAC Section 845.670(e)(1)(E) and IAC Section 845.680(d)(2). Table 2.5 summarizes and compares timeline and overall implementation schedule for both alternatives (also discussed in Sections 2.1.1 and 2.1.2).

[6] Sulfate was selected as a surrogate for the contaminant fate and transport simulations to evaluate the effectiveness of each of the corrective action alternative. Sulfate was detected in the PAP groundwater at the highest concentrations relative to its GWPS and it is expected to take the longest time to achieve GWPS. Modeling all constituents that exceed GWPS or have been detected at lower concentrations relative to their GWPSs is unnecessary, as these constituents will likely achieve their GWPSs more quickly (Gradient, 2024; Ramboll, 2025c).

Table 2.5 Estimated Timeline and Implementation Schedule for Source Control-GWP *vs.* Source Control-GWET

Implementation Phase	Implementation Task	Timeframe	
		Source Control-GWP	Source Control-GWET
1: Pre-Construction Activities[a] (Concurrent with Source Control)	Agency Coordination, Approvals, and Permitting	NA	18 to 24 months
	Final Design and Bid Process		24 to 36 months
	Timeframe to Complete Corrective		42 to 60 months after CAP Approval (3.5 to 5 years)
	Pre-Construction Activities		
2: Corrective Action Construction[a] (Concurrent with Source Control)	Corrective Action Construction	NA	9 to 18 months
	Timeframe to Complete Corrective Action Construction		9 to 18 months
3: Corrective Action O&M and Closeout[b] (After Completion of Source Control)	Corrective Action Monitoring (Time to Meet GWPS)	408 months (34 years)	396 months (33 years)
	Corrective Action Confirmation Monitoring	36 months	36 months
	Corrective Action Completion Reporting	6 months	6 months
	Timeframe to Complete Corrective Action O&M and Closeout	450 months (37.5 years)	438 months (36.5 years)
Total Timeline to Complete Corrective Action (All Phases)		450 months (37.5 years)	489 to 516 months (41 to 43 years)

Notes:
CAP = Corrective Action Plan; GWPS = Groundwater Protection Standard; NA = Non-applicable; O&M = Operations and Management; Source Control-GWET = Source Control with Groundwater Extraction Trench; Source Control-GWP = Source Control with Groundwater Polishing.
(a) Pre-construction Activities (Phase 1) and Corrective Action Construction (Phase 2) are assumed to occur concurrently with the source control (*i.e.*, closure-in-place or CIP) activities, to allow waste materials to be placed underneath the Primary Ash Pond (PAP) final cover system.
(b) Corrective Action O&M and Closeout (Phase 3) is assumed to start after the source control (*i.e.*, closure-in-place or CIP) is complete and approval of the corrective action construction permit application has been issued by Illinois Environmental Protection Agency (IEPA), whichever is longer.
Source: Appendix B; Ramboll, 2025b.

2.2.7 Potential for Exposure of Humans and Environmental Receptors to Remaining Wastes, Considering the Potential Threat to Human Health and the Environment Associated with Excavation, Transportation, Re-disposal, Containment, or Changes in Groundwater Flow (IAC Section 845.670(e)(1)(F))

Section 2.2.1 describes the magnitude of reduction of existing risks under each corrective action alternative. Section 2.2.2 describes the effectiveness of the remedy in controlling the source, including the extent to which containment practices would reduce further releases. Section 2.2.3 describes the likelihood of future releases of CCR occurring under each corrective action alternative, and Section 2.2.5 describes the short-term risks to workers, the community, and the environment during implementation of the remedy, including safety impacts and control of exposure to any residual contamination. In summary, source control measures (*i.e.*, CIP using a consolidate-and-cap approach) would be undertaken at the Site. Thus, both corrective action alternatives would completely eliminate the potential for a sudden CCR release to occur post-closure

(*e.g.*, due to flooding or a dike failure event). Similarly, due to the source control common to both of the corrective action alternatives, the two alternatives would both involve installing a new geomembrane cover system over the PAP, and no residual CCR exposures would be expected to occur during the implementation of any of the alternatives. Both corrective action alternatives would therefore be equally and fully protective with regard to exposure to residual CCR. There are no current or future risks to any human or ecological receptors at the Site, and there would be no risk of CCR releases post-closure.

For construction workers, risks arising from potential contact with residual contamination during construction, operation, and maintenance activities associated with residual plume management would be higher for the Source Control-GWET alternative than for the Source Control-GWP alternative because the Source Control-GWET would involve the production, management, and potential treatment of extracted groundwater, in addition to the disposal of excavated spoils underneath the final PAP cover system. The Source Control-GWP alternative would not involve exposure to either of these soil or groundwater waste streams. Any potential CCR exposures occurring under Source Control-GWET during groundwater extraction and treatment would be managed through the use of rigorous safety protocols, personal protective equipment, and appropriate disposal practice.

Some changes in groundwater flow (*i.e.*, controlled discharge into Newton Lake) may occur under the Source Control-GWET alternative, due to the operation of the GWET system. Hydrogeological changes would be expected under the Source Control-GWET alternative, such as lowering groundwater table in the vicinity of the extraction trench, altering flow patterns in the UA, and causing changes in hydraulic gradients. However, changes to groundwater flow would not be expected to have an effect on the potential for the exposure of humans and environmental receptors to remaining wastes.

2.2.8 Long-Term Reliability of the Engineering and Institutional Controls (IAC Section 845.670(e)(1)(G))

Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, the long-term reliability during source control would be the same for both corrective action alternatives (CAA) (Gradient, 2022a, 2025). The long-term reliability of the engineering and institutional controls associated with residual plume management of both corrective alternatives are summarized below.

- Residual plume management under the Source Control-GWP alternative would be reliable, because it would rely on natural physical and geochemical processes, rather than the installation, operation, and maintenance of engineered systems or structures. Under this alternative, engineering failure would not occur, and no O&M activities would be required to ensure the success of the alternative (other than those required for groundwater monitoring). Active groundwater monitoring would be in place to track the remediation progress. Should the predicted decrease in groundwater concentrations not occur, the adaptive site management approach would enable prompt adjustments or enhancements to the corrective action in accordance with IAC Section 845.680(b). This strategy would allow continuous improvement of the PAP groundwater remediation in response to new Site information and/or the performance of the corrective action alternative.
- GWET is a proven remedy that has been implemented at many sites. Thus, residual plume management under the Source Control-GWET alternative would be expected to be reliable provided it is constructed in accordance with standard design and specifications. Under this alternative, the extraction trench system and settling pond would require engineering design and installation for groundwater extraction and treatment. Routine maintenance of the GWET is required to ensure reliable operation of the extraction trench and pumps, as well as other system

components. Active groundwater monitoring would be in place, similar to those required under the Source Control-GWP alternative.

- For both corrective action alternatives, remedy optimizations would be implemented if necessary.

2.2.9 Potential Need for Replacement of the Remedy (IAC Section 845.670(e)(1)(H))

The potential need for the eventual replacement of the residual plume management remedy under each corrective action alternative is summarized as follows:

- Source Control-GWP would rely on natural physical geochemical processes to achieve reductions in groundwater concentrations to below the GWPSs. Because no installation, operation, and maintenance of engineered systems or structures would be required, it would be unlikely that the residual plume management remedy under the Source Control-GWP alternative would need to be replaced. Adaptive site management strategies would be used to implement remedy optimizations or replacement, as necessary based on data that are collected, to ensure that remedial goals are achieved.
- Source Control-GWET would utilize two extraction trenches and a new settling pond to extract and treat contaminated groundwater to achieve reductions in groundwater concentrations to below GWPSs. While the GWET system would need ongoing maintenance and potential replacement of system components over time, it is unlikely that the residual plume management remedy under the Source Control-GWET alternative would need to be replaced. Adaptive site management strategies would be used to implement remedy optimizations or replacement, as necessary based on data that are collected, to ensure that remedial goals are achieved.

2.3 The Ease or Difficulty of Implementing a Remedy (IAC Section 845.670 (e)(3))

2.3.1 Degree of Difficulty Associated with Constructing the Remedy (IAC Section 845.670(e)(3)(A))

Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, construction difficulties regarding source control would be the same for both corrective action alternatives. Difficulties associated with implementing CIP using a consolidate-and-cap approach were evaluated in the CAA (Gradient, 2022a, 2025). The expected degree of difficulty associated with residual plume management for each of the corrective action alternatives is summarized below.

- Residual plume management under the Source Control-GWP alternative would rely on physical and geochemical attenuation processes and therefore would not pose any significant construction challenges. This alternative would only require the use of monitoring wells, which are already installed. Therefore, there would be minimal difficulty in constructing the Source Control-GWP remedy.
- Residual plume management under the Source Control-GWET would involve the construction of an extraction trench, settling pond and conveyance system to extract and treat impacted groundwater and rely on physical and geochemical attenuation processes to address downgradient groundwater quality impacts. However, it may have the challenges, as described below, during construction of the extraction trenches (Appendix B; Ramboll, 2025b):

- The implementation of the remedy would require specialized contractors and equipment, specifically a one-pass trenching contractor and associated machinery, for trench installation. Additionally, general construction equipment, including excavation and grading machinery, would be required.
- Modifications to the PAP dike to establish an earthen work pad would require a detailed geotechnical design. Furthermore, geotechnical monitoring of the embankment would be essential to identify any signs of distress during construction. If distress is observed, construction activities may need to be temporarily halted to assess the cause and implement appropriate mitigation measures.
- Quality control (QC) monitoring would be required throughout the construction phase as part of the overall construction QC and quality assurance (QA) program, to ensure the effectiveness of the GWET system.
- Additional pre-design investigations may be necessary to confirm the existing hydrogeologic conditions along the proposed trench locations, to ensure the performance of the GWET.
- Groundwater monitoring would be conducted using a groundwater monitoring network designed in accordance with IAC Section 845.680(c).

2.3.2 Expected Operational Reliability of the Remedy (IAC Section 845.670(e)(3)(B))

Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, the operational reliability of the remedy would be the same for both corrective action alternatives. The reliability associated with implementing CIP using a consolidate-and-cap approach was evaluated in the CAA (Gradient, 2022a, 2025). Both corrective action alternatives would likely be highly reliable with respect to operational controls associated with residual plume management; specific details for each corrective action alternative are discussed below.

- Residual plume management under the Source Control-GWP alternative would have high operational reliability because it would rely on natural processes and active monitoring, rather than the installation, operation, and maintenance of engineered systems or structures (other than monitoring wells). Under the Source Control-GWP alternative, engineering failure would not occur and no O&M activities would be required to ensure the success of the alternative. Geochemical modeling results suggest that as groundwater returns to background conditions, solid sorbing phases are expected to be stable (Appendix E; Ramboll, 2024b).
- Residual plume management under the Source Control-GWET alternative would also have high operational reliability because it is an established and commonly used remedial technique, as long as the extraction trench system is constructed in accordance with the design and specifications. In addition, the mechanical system in this remedy would require routine and non-routine maintenance to ensure reliable operation.

2.3.3 Need to Coordinate with and Obtain Necessary Approvals and Permits from Other Agencies (IAC Section 845.670(e)(3)(C))

Both corrective action alternatives would require regulatory approvals. Specific permits and approvals associated with source control (*i.e.*, CIP using a consolidate-and-cap-approach) are the same for both corrective action alternatives and are discussed in the CAA (Gradient, 2022a, 2025). The specific approvals

and permits associated with residual plume management for both corrective action alternatives are discussed below.

- The Source Control-GWP alternative would not need additional permits from other agencies, other than the permits issued by IEPA for source control (*i.e.*, Closure Plan and Construction Permit Application) and approval of the eventual Corrective Action Plan.
- The Source Control-GWET alternative would require approvals and permits. Groundwater extracted from the GWET system would require a modified NPDES permit. The NPDES permits would likely require renewals depending on the timeline of corrective action implementation. In addition, permits from the IEPA for construction of stormwater controls and BMPs, placement of excavated spoils beneath the PAP final cover system *via* an amendment to the PAP Closure Plan and potentially an INDR Dam Safety modification permit would be required. These permits and plans typically take 18-24 months to obtain, although some may already be obtained during the PAP final closure (Appendix B; Ramboll, 2025b).

2.3.4 Availability of Necessary Equipment and Specialists (IAC Sections 845.670(e)(3)(D) and 845.660(c)(1), "Ease of Implementation")

Source control (*i.e.*, CIP using a consolidate-and-cap approach) would be implemented for both potential corrective action alternatives. Thus, equipment and specialist needs would be the same for source control activities associated with both corrective action alternatives. An assessment of necessary equipment and specialists associated with implementing CIP using a consolidate-and-cap approach was evaluated in the CAA (see the CAA; Gradient, 2022a, 2025). Specialized equipment and personnel are essential for field data collection and groundwater sampling for residual plume management under both potential corrective action alternatives. Additionally, the assessment of groundwater concentrations for Site constituents would necessitate laboratory equipment and specialists for both alternatives. The availability of equipment and specialists associated with residual plume management for each corrective action alternative is summarized below.

- Residual plume management under the Source Control-GWP alternative would require groundwater professionals, such as geologists, hydrogeologists, statisticians (for statistical analysis), and geochemists to evaluate all monitoring data, ensuring that physical and geochemical processes function as anticipated for this alternative. The equipment and specialists needed for Site groundwater monitoring and analysis are currently engaged in these tasks as part of the routine groundwater monitoring program outlined in accordance with IAC Section 845.220(c)(4).
- Residual plume management under the Source Control-GWET alternative would require specialists to manage the GWET system throughout its construction and operational period.
    - Construction of the groundwater extraction system (*i.e.*, the trench and settling pond) on the Site would require a specialized contractor, who would most likely need specialized and often custom-built equipment including one-pass construction equipment. Relatively few construction contractors with experience using one-pass equipment are available. Specialists including design engineers, construction managers and contractor staff experienced in trench construction and similar geologic environments will be required as well. Geotechnical specialist would be required to design the earthen work pad and oversee the PAP embankment for signs of distress during the one-pass trench installation. In addition, specialists and equipment may have backlogs from similar specialty ground improvement projects in the area.

- Specialist would be needed to maintain the operation of the GWET extraction system. System components such as totalizers, instrumentation, and the extraction and transfer pumps would require routine maintenance. Non-routine maintenance such as flushing or jetting of the conveyance lines, replacement of faulty system components, replacement of pumps system instrumentation, would also necessitate the use of specialist. Specialists and replacement equipment are typically available within 100 to 300 miles of the Site, but complex equipment like transfer pumps and controllers may have longer lead times for replacement or servicing.
- This alternative would necessitate the use of equipment and the expertise of specialists for tasks such as field data collection, groundwater sampling, analysis, and periodic corrective action groundwater monitoring and reporting. Similar to those in the GWP alternative, these activities are already being conducted as part of routine groundwater monitoring in accordance with IAC Section 845.220(c)(4).

2.3.5 Available Capacity and Location of Needed Treatment, Storage, and Disposal Services (IAC Section 845.670(e)(3)(D))

The available capacity and location of needed treatment, storage, and disposal services associated with residual plume management under each corrective action alternative are summarized below. All the practices employed in both alternatives would comply with standards for the management of wastes as specified in IAC Section 845.670(e)(3)(D) and IAC Section 845.680(d)(5).

- Residual plume management for the Source Control-GWP remedy would not require any treatment, storage, or disposal services, because GWP is not anticipated to produce a substantial amount of waste or wastewater, aside from minor purge water volumes generated during routine groundwater sampling activities for residual plume management. This could be managed by a standard waste management contractor.
- Residual plume management for the Source Control-GWET alternative would require the construction of the extraction trench system and a new settling pond on-Site:
  - The construction of the extraction trench would generate spoils, and the waste materials would be used as subgrade fill beneath the PAP final cover system during the closure construction. Finishing the extraction trench construction at the same time as the AP closure would provide sufficient on-Site capacity for the disposal of generated spoils
  - The extraction trench system would send extracted groundwater to an on-Site settling pond, which collects solids removed during groundwater recovery *via* the pneumatic extraction pumps and transfer piping. The settling pond would need to be sited, designed, constructed, and maintained properly. The siting of the settling pond would need to consider limiting impacts to existing Site infrastructure, wetlands, floodplains, and planned solar redevelopment for the Site.
  - Discharge from the settling pond would be conveyed to an NPDES permitted outfall. Renewal of the NPDES permits may be necessary to continue operations, depending on the timeline of the corrective action implementation in relation to the source control completion.

2.4 The Degree to Which Community Concerns Are Addressed by the Remedy (IAC Section 845.670(e)(4))

Several nonprofits raised concerns regarding the potential impacts of the PAP on groundwater and surface water quality including Earthjustice, the Prairie Rivers Network, and the Sierra Club (Earthjustice *et al*., 2018; Lydersen, 2017; Sierra Club and CIHCA, 2014). The combination of source control (*i.e*., CIP using a consolidate-and-cap approach) and residual plume management would cause groundwater concentrations to decline over time under all of the corrective action alternatives, as suggested by the groundwater modeling (Ramboll, 2025c), thus addressing these concerns.

A public meeting was held on February 26, 2025, pursuant to requirements under IAC Section 845.660(d). Questions raised by attendees were addressed at the meeting; a written summary of the questions and responses was prepared.

2.5 Remove from the Environment as Much of the Contaminated Material that Was Released from the CCR Surface Impoundment as Is Feasible, Taking into Account Factors such as Avoiding Inappropriate Disturbance of Sensitive Ecosystems (IAC Section 845.670(d)(4))

There have been no documented releases of CCR from the unit (Ramboll, 2025d). Both potential corrective action alternatives would have source control (*i.e*., CIP using a consolidate-and-cap approach) and residual plume management efforts. The source control would include the consolidation of CCR in the PAP into the northern and eastern portion of the impoundment and the installation of a low-permeability geomembrane final cover system designed to limit the infiltration of precipitation into the impounded CCR and tie into the surrounding grades. Updated groundwater modeling performed in support of the CAA (Gradient, 2022a, 2025) concluded that source control alone would result in a 99% reduction in mass flux from the PAP into the underlying groundwater (Ramboll, 2025c).

Moreover, residual plume management under each corrective action alternative will further result in the removal of contaminated material from the environment and/or the improvement of downgradient groundwater quality. Groundwater modeling has predicted GWPSs to be met in all monitoring wells in the existing PAP monitoring system within approximately 34 and 33 years, respectively, after source control has been implemented for the Source Control-GWP and the Source Control-GWET alternatives (Ramboll, 2025c).

- Residual plume management under the Source Control-GWP alternative would address impacted groundwater by relying on natural physical and geochemical attenuation processes to reduce the residual concentrations of CCR. Site-specific evaluation demonstrated that groundwater polishing is appropriate at PAP because Site conditions are suitable for physical and geochemical processes of inorganic contaminants *via* adsorption, although sorption of lithium is more pronounced compared to sulfate. Geochemical modeling results suggest that as groundwater returns to background conditions, solid sorbing phases are expected to be stable (Appendix E; Ramboll, 2024b). In cases in which observed groundwater concentrations deviate significantly from modeled conditions, alternative methods or techniques would be evaluated under the adaptive site management, and if viable, incorporated as per IAC Section 845.680(b). No ecosystems would be disturbed, because no construction activities would be expected under the Source Control-GWP alternative.

- Residual plume management under the Source Control-GWET alternative would utilize an engineered extraction system to remove constituent mass from the environment. Residual concentrations of CCR constituents in groundwater would also be reduced as a result of physical and geochemical attenuation processes. The construction activities would likely to result some negative impacts to the ecosystem, including disturbance of some existing habitats atop portions of the construction areas and habitats in the immediate vicinity of the Site by causing alarm and escape behavior in nearby wildlife (*e.g.*, due to noise disturbances). Short-term impacts could also occur to sensitive aquatic and wetland species in Newton Lake and other wetlands or surface water bodies located near PAP (see Section 1.1.3) due to sediment runoff during construction located near PAP.

2.6 Summary

This CAAA evaluates both corrective action alternatives identified as potentially viable in the CMA with regard to each of the factors specified in IAC Section 845.670(d) and 845.670(e) (IEPA, 2021). Based on this evaluation, the most appropriate corrective action for this Site is Source Control-GWP. While the time to achieve GWPS as predicted by groundwater modeling (excluding corrective action confirmation monitoring and completion reporting) is similar under both alternatives (34 years under Source Control-GWP *vs.* 33 years under Source Control with GWET), the expected impacts on workers, nearby communities, and the environment under the Source Control-GWP alternative are lower than the Source Control-GWET alternative. Thus, Source Control-GWP is the most appropriate corrective action alternative for the PAP.

1 Introduction

Illinois Power Generating Company's (IPGC) Newton Power Plant (NPP, or "the Site") is an electric power generating facility with coal-fired units located approximately seven miles southwest of the city of Newton, Illinois. The facility began operating in approximately 1977 and will be retired by the end of 2027 (Meeker, 2020; Ramboll, 2021). The NPP has one surface impoundment for storage of coal combustion residuals (CCR), known as the Primary Ash Pond (PAP), that was constructed in 1977 and covers approximately 404 acres (Ramboll, 2021). Closure of the PAP (Illinois Environmental Protection Agency [IEPA] ID No. W0798070001-01), which is the subject of this report, is planned to commence by the end of 2022.

This report presents the results of an evaluation that characterizes potential risk to human and ecological receptors that may be exposed to CCR constituents in environmental media originating from the PAP. This risk evaluation was performed to support the Closure Alternatives Assessment (CAA) for the PAP in accordance with requirements in Title 35 Part 845 of the Illinois Administrative Code (IAC) (IEPA, 2021). Human and ecological risks were evaluated for Site-specific constituents of interest (COIs). The conceptual site model (CSM) assumed that Site-related COIs in groundwater may migrate to the adjacent Newton Lake and affect surface water and sediment in the vicinity of the Site.

Consistent with United States Environmental Protection Agency (US EPA) guidance (US EPA, 1989), this report used a tiered approach to evaluate potential risks, which included the following steps:

1. Identify complete exposure pathways and develop a conceptual exposure model (CEM).
2. Identify Site-related COIs: Constituents detected in groundwater were considered COIs if their maximum detected concentration over the period from 2015 to 2021 exceeded a groundwater protection standard (GWPS) identified in Part 845.600 (IEPA, 2021), or a relevant surface water quality standard (IEPA, 2019; US EPA Region IV, 2018).
3. Perform screening-level risk analysis: Compare maximum measured or modeled COI concentrations in surface water and sediment to conservative, health-protective benchmarks in order to determine constituents of potential concern (COPCs).
4. Perform refined risk analysis: If COPCs are identified, perform a refined analysis to evaluate potential risks associated with the COPCs.
5. Formulate risk conclusions and discuss any associated uncertainties.

This assessment relies on a conservative (*i.e.*, health-protective) approach and is consistent with the risk approaches outlined in US EPA guidance. Specifically, we considered evaluation criteria detailed in IEPA guidance documents (*e.g.*, IEPA, 2013, 2019), incorporating principles and assumptions consistent with the Federal CCR Rule (US EPA, 2015a) and US EPA's "Human and Ecological Risk Assessment of Coal Combustion Residuals" (US EPA, 2014).

US EPA has established acceptable risk metrics. Risks above these US EPA-defined metrics are termed potentially "unacceptable risks". Based on the evaluation presented in this report, no unacceptable risks to human or ecological receptors resulting from CCR exposures associated with the PAP were identified. This means that the risks from the Site are likely indistinguishable from normal background risks. Specific risk assessment results include the following:

- No unacceptable risks were identified for recreators boating in Newton Lake adjacent to the Site.
- No unacceptable risks were identified for recreators exposed to sediment in Newton Lake adjacent to the Site.
- No unacceptable risks were identified for anglers consuming locally caught fish.
- No unacceptable risks were identified for ecological receptors exposed to surface water or sediment.
- No bioaccumulative ecological risks were identified.

It should be noted that this evaluation incorporates a number of conservative assumptions that tend to overestimate exposure and risk. Moreover, it should be noted that because current conditions do not present a risk to human health or the environment, there will also be no unacceptable risk to human health or the environment for future conditions when the PAP is closed. For all future closure scenarios, potential releases of CCR-related constituents will decline over time and consequently potential exposures to CCR-related constituents in the environment will also decline.

2 Site Overview

2.1 Site Description

The NPP is located in Jasper County Illinois, approximately seven miles southwest of the city of Newton. The PAP is located south of the power plant in a predominantly agricultural area. The PAP is surrounded by Newton Lake on the west, south, and east (Figure 2.1) (Ramboll, 2021). Three CCR units are present on the NPP property, including the PAP and two landfills; the Phase 1 Landfill (LF 1) is located northwest and west of the PAP, and the Phase 2 Landfill (LF 2) is located west of the PAP. The PAP is the subject of this report (Ramboll, 2021). The PAP discharges into a secondary pond located immediately south of the PAP, which then discharges to Newton Lake under a National Pollutant Discharge Elimination System (NPDES) permit (No. IL0049191) (Ramboll, 2021).

Newton Lake was formed by the construction of a dam in 1975 (US National Dams, 2022), and is used as a cooling water supply for the NPP (IDNR, 2019). Water is drawn from the eastern arm near the power plant and thermal effluent is released at two locations in the western arm via NPDES permitted outfalls (IEPA, 2016).

Figure 2.1 Site Location Map. Source: Ramboll, 2021.

2.2 Geology/Hydrogeology

The geology underlying the Site in the vicinity of the PAP primarily consists of unlithified deposits overlying a shale bedrock unit. The principal types of unlithified materials include the Peoria Silt /Sangman Soil, the Hagarstown Member, the Vandalia Till, the Mulberry Grove Member, and the Smithboro Till/Banner Formation (Ramboll, 2021). These unlithified deposits are underlain by a Pennsylvanian Age shale bedrock of the Mattoon Formation (Ramboll, 2021). Five distinct hydrostratigraphic units in the area are (listed from ground surface down): the Upper Drift (UD)/Potential Migration Pathway (PMP), the Upper Confining Unit (UCU), the Uppermost Aquifer (UA), the Lower Confining Unit (LCU), and the Bedrock Confining Unit (BCU) (Ramboll, 2021).

The UD is composed of low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.*, PMP). The Hagarstown Member is generally 2 feet (ft) thick but is encountered at thicknesses up to about 6.9 ft in the vicinity of the Ash Pond (Ramboll, 2021). The UD/PMP has a geometric mean horizontal hydraulic conductivity of 3.1×10^{-3} cm/s (Ramboll, 2021). The UA is composed of a 3 to 17 ft thick Mulberry Grove Member, which consists of sand, silty- and clayey-sand, and gravel. The UA has a geometric mean horizontal hydraulic conductivity of 6.8×10^{-3} cm/s (Ramboll, 2021). The UA is sandwiched between two low-permeability confining units: (i) the UCU on

top consisting of clay and silt of the Vandalia Till and (ii) the LCU on bottom consisting of silt and clay of the Smithboro Till Member and the Banner Formation (Ramboll, 2021). No wells are screened within the UCU, the LCU, or the underlying shale BCU. Field hydraulic conductivity tests were not performed in any of these confining units (Ramboll, 2021).

Groundwater within the UA flows generally from the north towards the south and southwest. In the southern area of the PAP, groundwater flows toward a former drainage feature located west of the PAP (Ramboll, 2021). In the northern area of the PAP, groundwater from the UA may interact with surface water in Newton Lake, as evidenced by relatively higher groundwater head elevations compared to the Newton Lake water level. Groundwater velocities in the UA range from 0.04 to 1.9 ft/day. Horizontal hydraulic gradients calculated for the UA range from 0.0025 to 0.0071 ft/ft (Ramboll, 2021). Groundwater within the UD/PMP may also flow into Newton Lake; however, flow velocity or hydraulic gradient have not been calculated or measured within the PMP (Ramboll, 2021).

2.3 Conceptual Site Model

A CSM describes sources of contamination, the hydrogeological units, and the physical processes that control the transport of water and solutes. In this case, the CSM describes how groundwater underlying the PAP migrates and interacts with surface water and sediment in the adjacent Newton Lake. The CSM was developed using available hydrogeologic data specific to the PAP (Ramboll, 2021), including information on groundwater flow and surface water characteristics.

CCR-related constituents may migrate vertically downward beneath the PAP and into groundwater; these constituents may subsequently migrate with groundwater in the UA and the PMP and flow into the eastern arm of Newton Lake. CCR-related constituents from the PAP may migrate vertically downward through the UD/PMP and the UCU into the UA (Ramboll, 2021). The north to south groundwater flow within the UA is mostly in the horizontal direction because the UA is underlain by two low-permeability confining units (*i.e.*, LCU and BCU) that inhibit vertical flow (Ramboll, 2021). A component of the CCR-related constituents from the PMP may also flow into Newton Lake, particularly on the eastern portion of the PAP where groundwater and surface water interact. After groundwater flows into the lake, dissolved constituents in groundwater may partition between sediments and surface water.

2.4 Groundwater Monitoring

A total of 29 wells have been used to monitor the groundwater quality near and downgradient of the PAP. Of these, 23 wells are screened in the UA, and 6 wells are screened in the UD (Table 2.1). The analyses presented in this report relied on all available data from the 29 wells collected between 2015 and 2021, which is the period subsequent to the promulgation of the Federal CCR Rule. Groundwater samples were analyzed for a suite of total metals, specified in Illinois CCR Rule Part 845.600 (IEPA, 2021).[1] A summary of the groundwater data used in this risk evaluation is presented in Table 2.2. The PAP well locations are shown in Figure 2.2. Note that there are additional wells in the vicinity of the PAP (shown in Figure 2.1) that were not used in this risk analysis, because they were screened in the CCR and are not reflective of groundwater conditions. The use of groundwater data in this risk evaluation does not imply that detected constituents are associated with the PAP or that they have been identified as potential groundwater exceedances.

[1] Samples were analyzed for a longer list of inorganic constituents and general water quality parameters (chloride, fluoride, sulfate, and total dissolved solids), but these constituents were not evaluated in the risk evaluation.

2.5 Surface Water Monitoring

Golder collected a total of 28 surface water samples from Newton Lake in the vicinity of the PAP in April and May, 2021 (Golder Associates Inc., 2021). The sample locations are shown in Figure 2.3, and the sampling results are summarized in Table 2.3.

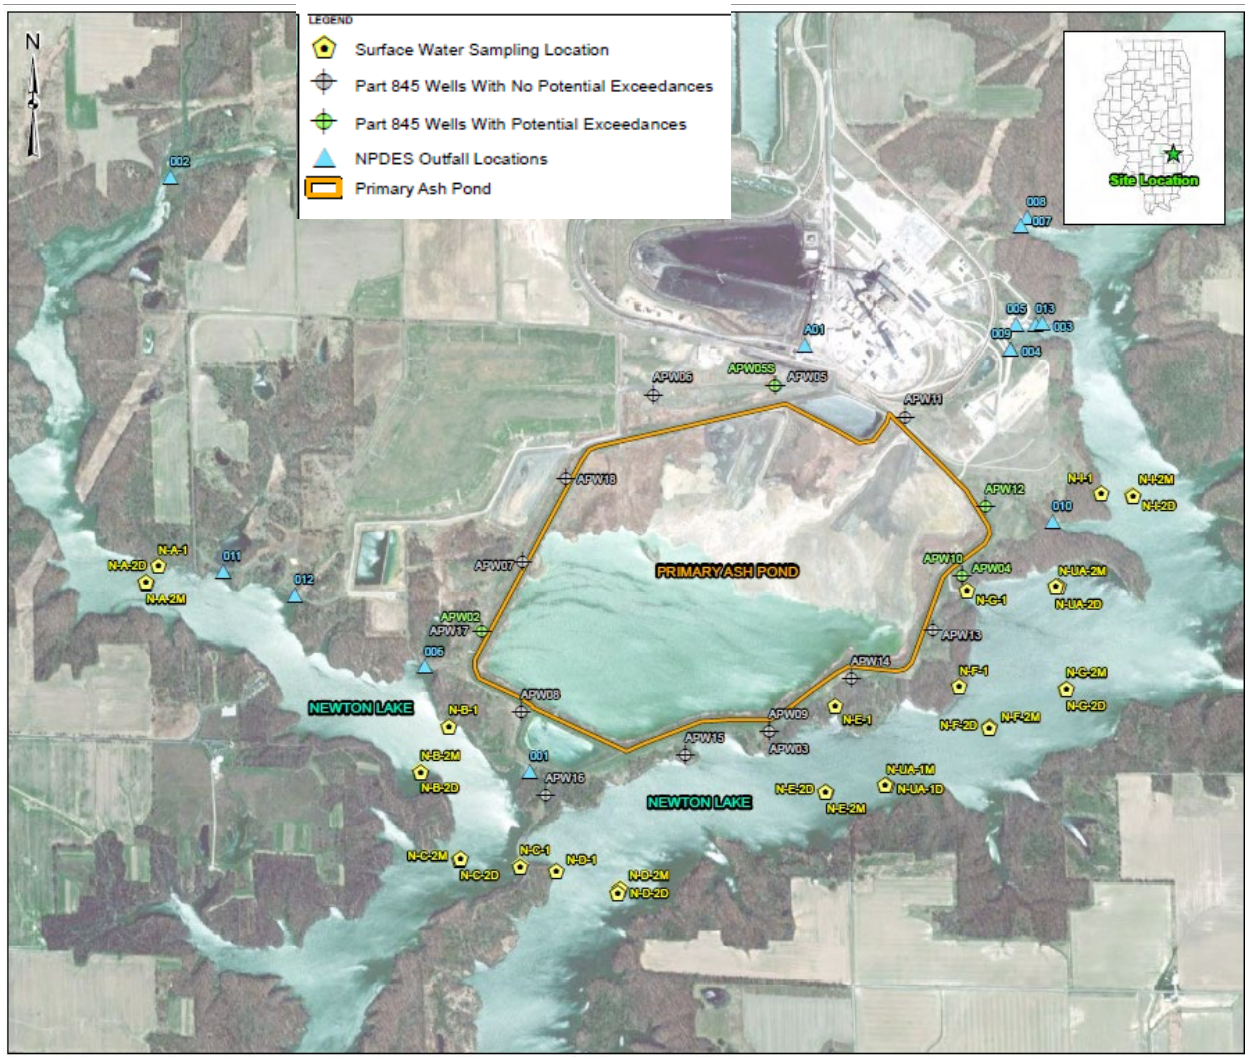

Figure 2.3 Surface Water Sampling Locations. Source: Golder Associates Inc., 2021.

Table 2.3 Surface Water Data Summary

Constituent	Samples with Constituent Detected	Samples Analyzed	Minimum Detected Value	Maximum Detected Value	Maximum Laboratory Detection Limit
Total Metals (mg/L)					
Antimony	0	28			0.003
Arsenic	28	28	0.0018	0.0042	0.001
Barium	28	28	0.052	0.64	0.001
Beryllium	0	28			0.001

Radionuclides (pCi/L)					
Radium-226+228	28	28	0.012	2.1	1.09
Other (mg/L)					
Chloride	28	28	8.5	9.6	1
Fluoride	28	28	0.35	0.51	0.25
Sulfate	28	28	35	95	25
Total Dissolved Solids	28	28	170	240	34

Notes:

COI = Constituent of Interest; pCi/L = PicoCuries Per Liter.

Surface water was analyzed for both total and dissolved metals; only total metals are reported here because they generally have higher concentrations than dissolved metals. However, the maximum dissolved concentrations for boron, manganese, and molybdenum are slightly higher (up to a factor of two) than the maximum total concentrations, but boron, manganese, and molybdenum have not been identified as COIs.

3 Risk Evaluation

3.1 Risk Evaluation Process

A risk evaluation was conducted to determine whether constituents present in groundwater underlying and downgradient of the PAP have the potential to pose adverse health effects to human and ecological receptors. The risk evaluation is consistent with the principles of risk assessment established by US EPA and has considered evaluation criteria detailed in Illinois guidance documents (*e.g.*, IEPA, 2013, 2019).

The general risk evaluation approach is summarized in Figure 3.1 and discussed below.

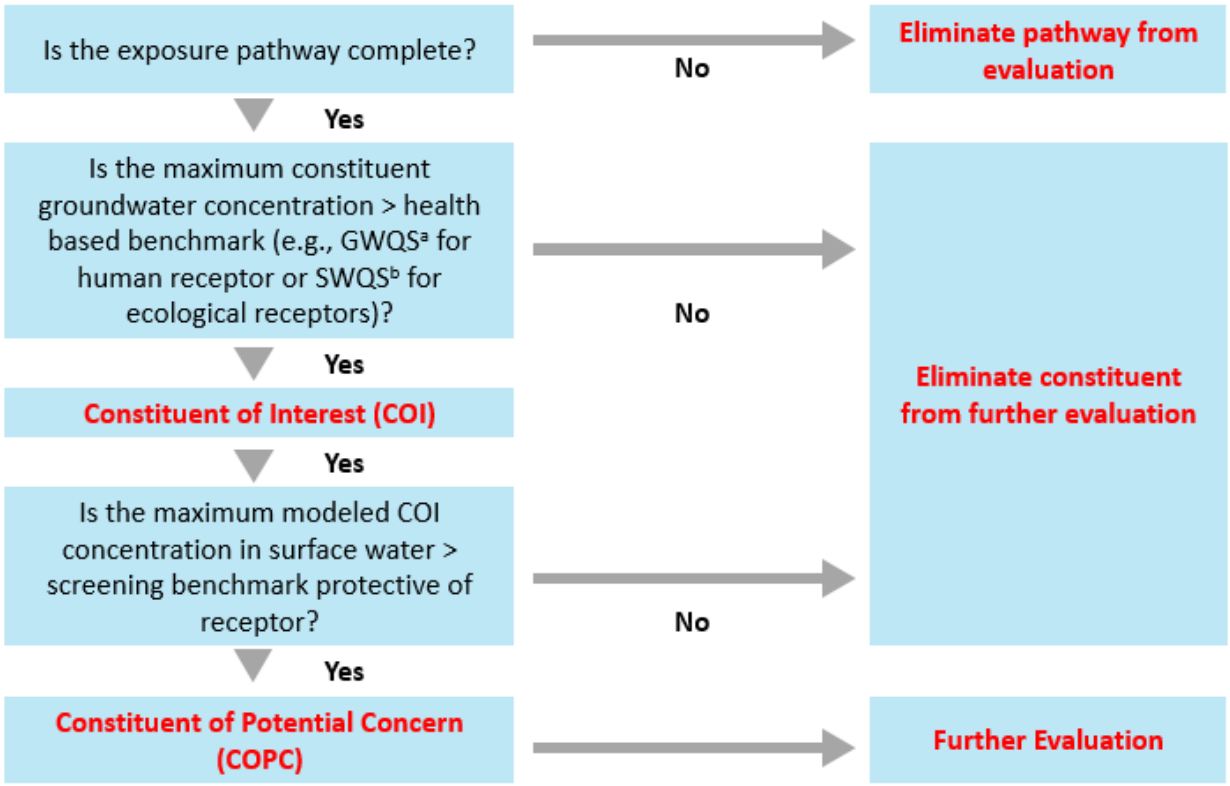

Figure 3.1 Overview of Risk Evaluation Methodology. IEPA = Illinois Environmental Protection Agency; GWQS = IEPA Groundwater Quality Standards; SWQS = IEPA Surface Water Quality Standards. (a) The IEPA Part 845 Groundwater Protection Standards (GWPS) were used to identify COIs. (b) IEPA SWQS protective of chronic exposures to aquatic organisms were used to identify ecological COIs. In the absence of an SWQS, US EPA Region IV Ecological Screening Values (ESVs) were used.

The first step in the risk evaluation was to develop the CEMs and identify complete exposure pathways. All potential receptors and exposure pathways based on groundwater use and surface water use in the vicinity of the Site were considered. Exposure pathways that are incomplete were excluded from the evaluation.

Groundwater data were used to identify COIs. COIs were identified as constituents with maximum concentrations in groundwater in excess of groundwater quality standards (GWQS)[2] for human receptors and surface water quality standards (SWQS) for ecological receptors. Based on the CSM (Section 2.2), some groundwater underlying the PAP has the potential to interact with surface water in Newton Lake. Therefore, potential PAP-related constituents in groundwater may potentially flow toward and into surface water in Newton Lake.

Surface water samples have been collected from Newton Lake adjacent to the Site; however, sediment samples have not been collected from the lake. Gradient modeled the potential migration of COIs from groundwater to surface water and sediment to evaluate potential risks to receptors (see Section 3.3.3).

Gradient modeled the COI concentrations in surface water and sediment based on the groundwater data from the PAP-related wells. The measured and modeled COI concentrations in surface water and sediment were compared to conservative, generic risk-based screening benchmarks for human health and ecological receptors. These generic screening benchmarks rely on default assumptions with limited consideration of site-specific characteristics. Human health benchmarks are receptor-specific values calculated for each pathway and environmental medium that are designed to be protective of human health. Ecological benchmarks are medium-specific values designed to be protective of all potential ecological receptors exposed to surface water. Ecological and human health screening benchmarks are inherently conservative because they are intended to screen out chemicals that are of no concern with a high level of confidence. Therefore, a measured or modeled COI concentration exceeding a screening benchmark does not indicate an unacceptable risk, but only that further risk evaluation is warranted. COIs with maximum concentrations exceeding a conservative screening benchmark are identified as COPCs requiring further evaluation.

As described in more detail below, this evaluation relied on the screening assessment to demonstrate that constituents present in groundwater underlying the PAP do not pose an unacceptable human health or ecological risk. That is, after the screening step, no COPCs were identified and further assessment was not warranted.

3.2 Human and Ecological Conceptual Exposure Models

A CEM provides an overview of the receptors and exposure pathways requiring risk evaluation. The CEM describes the source of the contamination, the mechanism that may lead to a release of contamination, the environmental media to which a receptor may be exposed, the route of exposure (exposure pathway), and the types of receptors that may be exposed to these environmental media.

3.2.1 Human Conceptual Exposure Model

The human CEM for the Site depicts the relationships between the off-Site environmental media potentially impacted by constituents in groundwater and human receptors that could be exposed to these media. Figure 3.2 presents a human CEM for the Site. It considers a human receptor who could be exposed to COIs hypothetically released from the PAP into groundwater, surface water, sediment, and fish. The following human receptors and exposure pathways were evaluated for inclusion in the Site-specific CEM.

[2] As discussed further in Section 3.3.2, GWQS are protective of human health and not necessarily of ecological receptors. While ecological receptors are not exposed to groundwater, groundwater can potentially enter into the adjacent surface water and impact ecological receptors. Therefore, two sets of COIs were identified: one for humans and another for ecological receptors.

- Residents – exposure to groundwater/surface water as drinking water;
- Residents – exposure to groundwater/surface water used for irrigation;
- Recreators in the lake adjacent to the Site:
  - Boaters – exposure to surface water and sediment while boating;
  - Swimmers – exposure to surface water and sediment while swimming;
  - Anglers – exposure to surface water and sediment and consumption of locally caught fish.

All of these exposure pathways were considered to be complete, except for residential exposure to groundwater or surface water used for drinking water or irrigation, and swimming. Section 3.2.1.1 explains why the residential drinking water and irrigation pathways are incomplete, and Section 3.2.1.2 provides additional description of the recreational exposures. While a recreator's potential exposure to surface water in Newton Lake was evaluated, swimming does not occur in Newton Lake, because it is owned by IPGC and used as a cooling reservoir (IDNR, 2022).

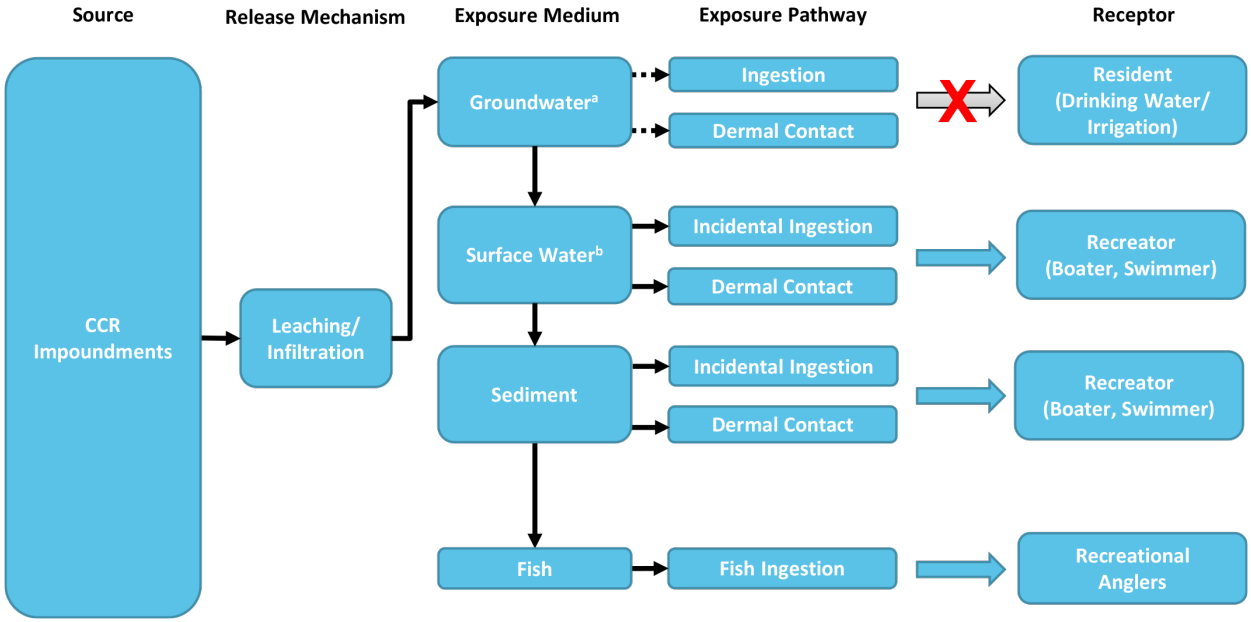

Figure 3.2 Human Conceptual Exposure Model. CCR = Coal Combustion Residual. Dashed line/Red X = Incomplete or insignificant exposure pathway. (a) Groundwater in the vicinity of the Site is not used as a drinking water or irrigation source. (b) Surface water is not used as a drinking water source.

3.2.1.1 Groundwater or Surface Water as a Drinking Water/Irrigation Source

Groundwater as a source of drinking water and/or irrigation water is not a complete exposure pathway for CCR-related constituents originating from the PAP. Specifically, shallow groundwater from the UA and the PMP in the vicinity of the PAP is not used as a source of drinking water, and no potable wells were identified downgradient of the PAP. A summary of the evidence supporting the conclusion that there are no residential uses of the shallow groundwater and Newton Lake surface water as a source of drinking water is presented below:

- **No potential groundwater receptors are in the vicinity of the PAP**. Relying on state databases, Ramboll completed a potable water well survey in 2021 (Ramboll, 2021). Two wells[3] were identified within a 1,000-meter radius of the PAP boundary during a comprehensive search of the Illinois State Geological Survey's (ISGS) Illinois Water and Related Wells (ILWATER) Map (ISGS, 2020) (Figure 3.3). Both wells are listed as dry/abandoned and are not currently in use as a source of drinking water (Ramboll, 2021).
- **There is no off-Site migration of CCR-related constituents in groundwater**. Newton Lake is intersected by both the UA and the PMP; thus, groundwater from the UA and the PMP may interact with surface water in the lake in some areas. The two water wells that are identified within a 1,000 m radius of the PAP are located on the southeast side of Newton Lake, *i.e.*, the opposite side of the lake from the PAP. Thus, Newton Lake separates the wells from the PAP (Figure 3.3). CCR-constituents in groundwater within the UA and the PMP are not expected to flow underneath or bypass Newton Lake.
- **Newton Lake adjacent to the PAP is not used as a public water supply.** Newton Lake is a cooling water pond owned and maintained by IPGC. IPGC restricts the use of the pond as a source of drinking water. Therefore, the human exposure pathway of surface water ingestion (as potable water) adjacent to the PAP was not evaluated further.
- **The PAP has a limited hydraulic connection to underlying groundwater**. The LCU and the shale BCU underlying the shallow aquifers (*i.e.*, the UA and the PMP) form a hydraulic barrier between the PAP and deeper groundwater resources. Due to the very low hydraulic conductivity of these confining units, downward migration of shallow groundwater is expected to be limited. Therefore, the likelihood of PAP-related impacts to deep groundwater is minimal.

[3] These are well numbers 120790038600 and 120790043600 (Ramboll, 2021).

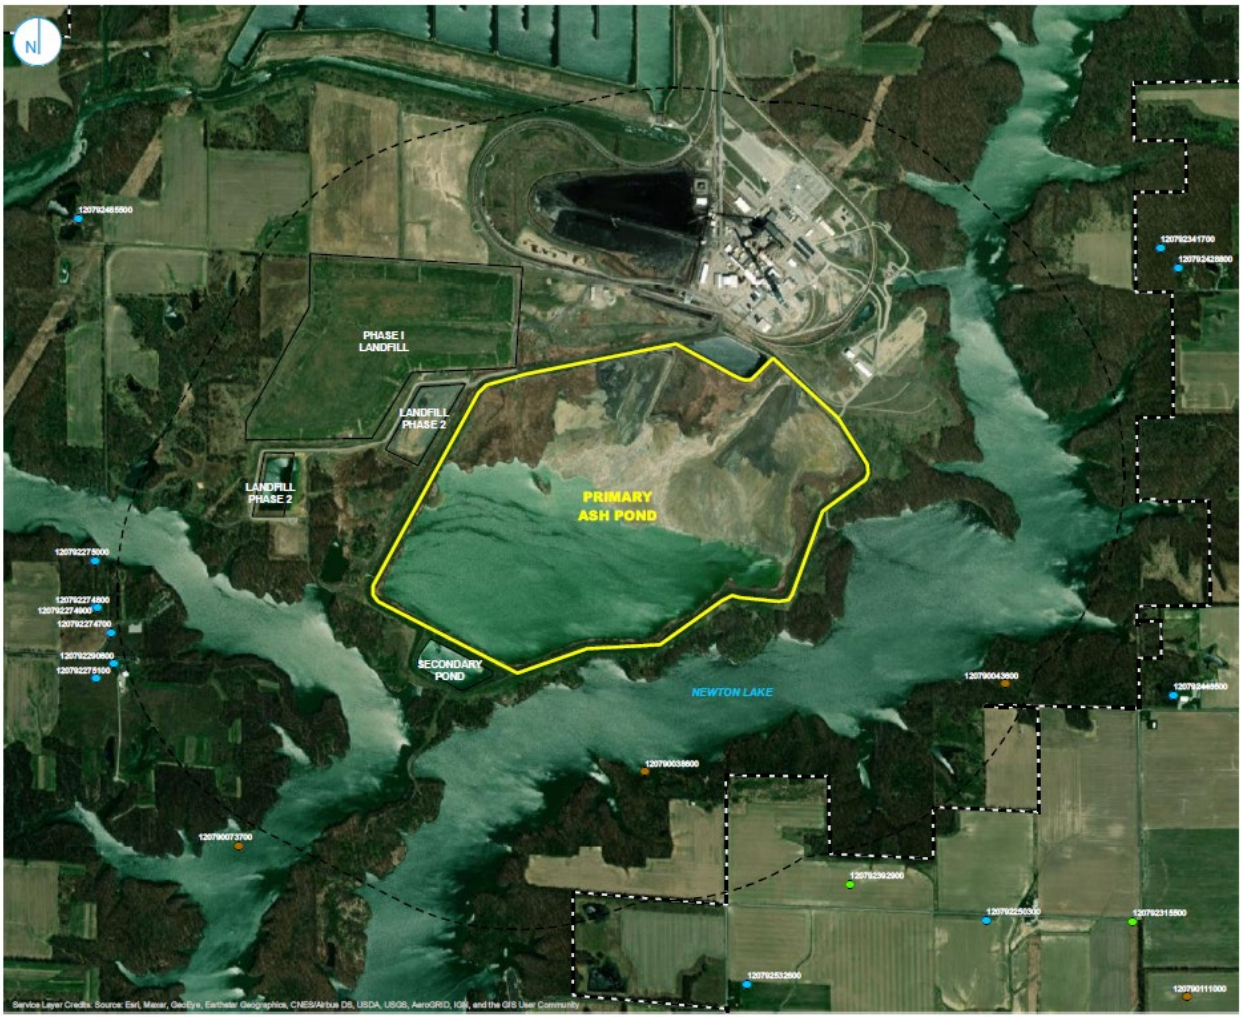

Figure 3.3 Water Wells Within 1,000 meters of the Primary Ash Pond. Source: Ramboll, 2021, Figure B-1.

3.2.1.2 Recreational Exposures

Newton Lake is located adjacent to the Site and is owned by IPGC. A portion of the NPP property along the lake has been leased to the Illinois Department of Natural Resources (IDNR) for use as a State Fish and Wildlife Area; thus, the lake is used for recreational fishing (IDNR, 2019). Recreational exposure to surface water and sediment may occur during activities such as boating or fishing in the lake. Recreational anglers may also consume locally caught fish from Newton Lake. Swimming does not occur in Newton Lake because it is owned by IPGC and used as a cooling reservoir (IDNR, 2022).

3.2.2 Ecological Conceptual Exposure Model

The ecological CEM for the Site depicts the relationships between off-Site environmental media (surface water and sediment) potentially impacted by COIs in groundwater and ecological receptors that may be exposed to these media. The ecological risk evaluation considered both direct toxicity as well as secondary toxicity *via* bioaccumulation. Figure 3.4 presents the ecological CEM for the Site. The following ecological receptor groups and exposure pathways were considered:

- **Ecological Receptors Exposed to Surface Water:**
  - Aquatic plants, amphibians, reptiles, and fish.
- **Ecological Receptors Exposed to Sediment:**
  - Benthic invertebrates (*e.g.*, insects, crayfish, mussels).
- **Ecological Receptors Exposed to Bioaccumulative COIs:**
  - Higher trophic-level wildlife (avian and mammalian) *via* direct exposures (surface water and sediment exposure) and secondary exposures through the consumption of prey (*e.g.*, plants, invertebrates, small mammals, fish).

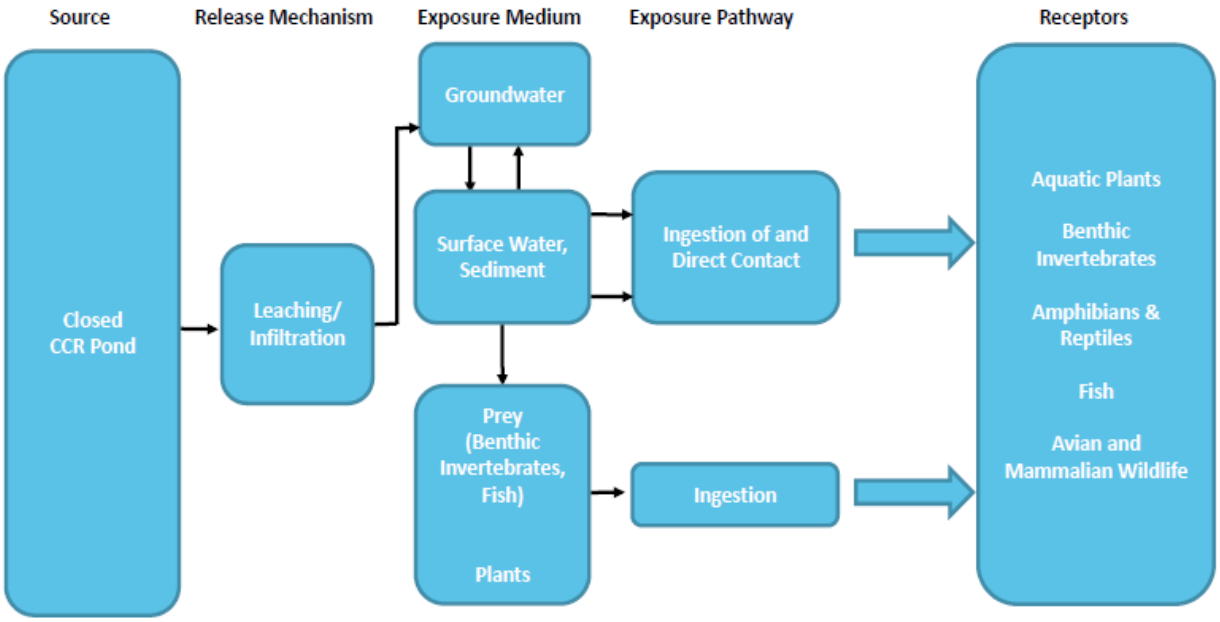

Figure 3.4 Ecological Conceptual Exposure Model. CCR = Coal Combustion Residual.

3.3 Identification of Constituents of Interest

Risks were evaluated for COIs. A constituent was considered a COI if the maximum detected constituent concentration in groundwater exceeded a health-based benchmark. According to US EPA risk assessment guidance (US EPA, 1989), this screening step is designed to reduce the number of constituents carried through the risk evaluation that are anticipated to have a minimal contribution to the overall risk. Identified COIs are the constituents that are most likely to pose a risk concern in the surface water adjacent to the Site.

3.3.1 Human Health Constituents of Interest

For the human health risk evaluation, COIs were conservatively identified as constituents with maximum concentrations in groundwater above the GWPS listed in the Illinois CCR Rule Part 845.600 (IEPA, 2021). Gradient used the maximum detected concentrations from groundwater samples collected from all of the PAP-associated wells, regardless of hydrostratigraphic unit. The use of groundwater data in this risk evaluation does not imply that detected constituents are associated with the PAP or that they have been identified as potential groundwater exceedances. Using this approach, 7 COIs (arsenic, cobalt, lead,

lithium, thallium, radium-226+228, and fluoride) were identified for the human health risk evaluation *via* the surface water pathway (Table 3.1).

The water quality parameters that exceeded the GWPS included chloride, sulfate, and total dissolved solids; however, these constituents were not included in the risk evaluation because the GWPS is based on aesthetic quality and there is an absence of studies regarding toxicity to human health. The US EPA secondary maximum contaminant levels (MCLs) for chloride, sulfate, and total dissolved solids are based on aesthetic quality. The secondary MCLs for chloride and sulfate (250 mg/L) are based on salty taste (US EPA, 2021a). The secondary MCL for total dissolved solids (500 mg/L) is based on hardness, deposits, colored water, staining, and salty taste (US EPA, 2021a). Given that these parameters are not likely to pose a human health risk concern in the event of exposure, they were not considered to be human health COIs.

Table 3.1 Human Health Constituents of Interest

Constituents[a]	Maximum Concentration	GWPS[b]	Human Health COI[c]
Total Metals (mg/L)			
Antimony	0.0036	0.0060	No
Arsenic	0.13	0.010	Yes
Barium	1.5	2.0	No
Beryllium	0.0033	0.0040	No
Boron	0.66	2.0	No
Cadmium	0.0034	0.0050	No
Chromium	0.090	0.10	No
Cobalt	0.036	0.0060	Yes
Lead	0.065	0.0075	Yes
Lithium	0.30	0.040	Yes
Mercury	0.0020	0.0020	No
Molybdenum	0.045	0.10	No
Selenium	0.0060	0.050	No
Thallium	0.0036	0.0020	Yes
Radionuclides (pCi/L)			
Radium-226+228	15	5.0	Yes
Other (mg/L)			
Chloride	550	200	No[d]
Fluoride	8.2	4.0	Yes
Sulfate	3,200	400	No[d]
Total Dissolved Solids	5,500	1,200	No[e]

Notes:
COI = Constituent of Interest; GWPS = Groundwater Protection Standard; MCL = Maximum Contaminant Level; pCi/L = PicoCuries Per Liter.
Shaded = Compound identified as a COI.
(a) The constituents are those listed in the IL Part 845.600 GWPS (IEPA, 2021).
(b) The IL Part 845.600 GWPS (IEPA, 2021) were used to identify COIs.
(c) COIs are constituents for which the maximum concentration exceeds the groundwater standard.
(d) This constituent is not likely to pose a human health risk concern due to the absence of studies regarding toxicity to human health. Therefore, this constituent is not considered a COI.
(e) Total dissolved solids are not considered a COI because the MCL is based on aesthetic quality.

3.3.2 Ecological Constituents of Interest

The Illinois GWPS, as defined in IEPA's guidance, were developed to protect human health but not necessarily ecological receptors. While ecological receptors are not exposed to groundwater, groundwater can potentially migrate into the adjacent surface water and impact ecological receptors. Therefore, to identify ecological COIs, the maximum concentrations of constituents detected in groundwater were compared to ecological surface water benchmarks protective of aquatic life.

The surface water screening benchmarks for freshwater organisms were obtained from the following hierarchy of sources:

- IEPA (2019) SWQS. IEPA SWQS are health-protective benchmarks for aquatic life exposed to surface water on a long-term basis (*i.e.*, chronic exposure). The SWQS for several metals are hardness dependent (cadmium, chromium, copper, lead, manganese, nickel, and zinc). Screening benchmarks for these constituents were calculated assuming US EPA's default hardness of 100 mg/L (US EPA, 2022).[4]
- US EPA Region IV (2018) surface water Ecological Screening Values (ESVs) for hazardous waste sites.

Benchmarks from the United States Department of Energy's (US DOE) guidance document ("A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota") were used for radium (US DOE, 2019). US DOE presents benchmarks for radium-226 and radium-228 (4 and 3 picoCuries per liter [pCi/L], respectively). Given that radium concentrations are expressed as total radium (radium-226+228, *i.e.*, the sum of radium-226 and radium-228), Gradient used the lower of the two benchmarks (3 pCi/L for radium-228) to evaluate total radium concentrations.

Consistent with the human health risk evaluation, Gradient used the maximum detected concentrations from groundwater samples collected from all of the PAP-associated wells, (regardless of hydrostratigraphic unit) without considering spatial or temporal representativeness for ecological receptor exposures. The use of the maximum constituent concentrations in this evaluation is designed to conservatively identify COIs that warrant further investigation. Cadmium, cobalt, lead, mercury, radium-226+228, chloride, and fluoride were identified as COIs for ecological receptors (Table 3.2).

[4] Hardness data are not available for Newton Lake adjacent to the Site, therefore, the US EPA (2022) default hardness of 100 mg/L was used. Use of a higher hardness value would result in less stringent screening values, thus, use of the US EPA default hardness is conservative.

Table 3.2 Ecological Constituents of Interest

Constituents[a]	Maximum Groundwater Concentration	Ecological Benchmark[b]	Basis	Ecological COI[c]
Total Metals (mg/L)				
Antimony	0.0036	0.19	US EPA R4 ESV	No
Arsenic	0.13	0.19	IEPA SWQC	No
Barium	1.5	5.0	IEPA SWQC	No
Beryllium	0.0033	0.064	US EPA R4 ESV	No
Boron	0.66	7.6	IEPA SWQC	No
Cadmium	0.0034	0.0011	IEPA SWQC	Yes
Chromium	0.09	0.21	IEPA SWQC	No
Cobalt	0.036	0.019	US EPA R4 ESV	Yes
Lead	0.065	0.020	IEPA SWQC	Yes
Lithium	0.3	0.44	US EPA R4 ESV	No
Mercury	0.002	0.0011	IEPA SWQC	Yes
Molybdenum	0.045	7.2	US EPA R4 ESV	No
Selenium	0.006	1.0	IEPA SWQC	No
Thallium	0.0036	0.0060	US EPA R4 ESV	No
Radionuclides (pCi/L)				
Radium-226+228	15.2	3.0	US DOE	Yes
Other (mg/L, unless otherwise noted)				
Chloride	550	500	IEPA SWQC	Yes
Fluoride	8.16	4.0	IEPA SWQC	Yes
Sulfate	3200	NA	NA	No
Total Dissolved Solids	5500	NA	NA	No

Notes:
COI = Constituent of Interest; DOE = Department of Energy; GWPS = Groundwater Protection Standard; IEPA SWQS = Illinois Environmental Protection Agency Surface Water Quality Standards; NA = Not Available; PAP = Primary Ash Pond; pCi/L = PicoCuries Per Liter; US EPA R4 ESV = US Environmental Protection Agency Region IV Ecological Screening Value.
Shaded = Compound identified as a COI.
(a) The constituents are those listed in the IL Part 845.600 GWPS (IEPA, 2021) that were detected in at least one groundwater sample from the wells related to the Newton PAP.
(b) Ecological benchmarks are from the hierarchy of sources discussed in Section 3.3.2: IEPA SWQS (IEPA, 2019); US EPA R4 "Ecological Risk Assessment Supplemental Guidance" (US EPA Region IV, 2018); and US DOE's guidance document "A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota" (US DOE, 2019).
(c) Constituents with maximum detected concentrations exceeding a benchmark protective of surface water exposure are considered ecological COIs.

3.3.3 Surface Water and Sediment Modeling

Surface water sampling has been conducted in Newton Lake adjacent to the Site. To estimate the potential contribution to surface water (and sediment) from groundwater specifically associated with the PAP, Gradient modeled concentrations in Newton Lake surface water and sediment from groundwater flowing into the lake for the detected human and ecological COIs. This is because the constituents detected in groundwater above an ecological or health-based benchmark are most likely to pose a risk concern in the adjacent surface water. Gradient modeled human health and ecological COI concentrations in the surface water and sediment using a mass balance calculation based on the surface water and groundwater mixing. The model assumes a well-mixed groundwater-surface water location. The maximum detected

concentrations in groundwater (regardless of well location) from 2015 to 2021 were conservatively used to model COI concentrations in surface water and sediment. The groundwater data were measured as total metals. Use of the total metal concentration for these COIs may overestimate surface water concentrations because dissolved concentrations, which are lower than total concentrations, represent the mobile fractions of constituents that could likely flow into and mix with surface water.

The modeling approach does not account for geochemical transformations that may occur during groundwater mixing with surface water. Gradient assumed that predicted surface water concentrations were influenced only by the physical mixing of groundwater as it enters the surface water and were not further influenced by the geochemical reactions in the water and sediment, such as precipitation. In addition, the model only predicts surface water and sediment concentrations as a result of the potential migration of COI concentrations in PAP-related groundwater and does not account for background concentrations in surface water or sediment.

For this evaluation, Gradient adapted a simplified and conservative form of US EPA's indirect exposure assessment methodology (US EPA, 1998) that was used in US EPA's coal combustion waste risk assessment (US EPA, 2014). The model is a mass balance calculation based on surface water and groundwater mixing and the concept that the dissolved and sorbed concentrations can be related through an equilibrium partitioning coefficient (K_d). The model assumes a well-mixed groundwater-surface water location, with partitioning among total suspended solids, dissolved water column, sediment pore water, and solid sediments.

Sorption to soil and sediment is highly dependent on the surrounding geochemical conditions. To be conservative, we ignored the natural attenuation capacity of soil and sediment and estimated the surface water concentration based only on the physical mixing of groundwater and surface water (*i.e.*, dilution) at the point where groundwater flows into surface water.

The aquifer and surface water properties used to estimate the volume of groundwater flowing into Newton Lake and surface water concentrations are presented in Table 3.3. The COI concentrations in sediment were modeled using the COI-specific sediment-to-water partitioning coefficients and the sediment properties presented in Table 3.4. In the absence of Site-specific information for Newton Lake, Gradient used default assumptions (*e.g.*, depth of the upper benthic layer and bed sediment porosity) to model sediment concentrations. The modeled surface water and sediment concentrations are presented in Table 3.5. These modeled concentrations reflect conservative contributions from groundwater. A description of the modeling and the detailed results are presented in Appendix A.

Table 3.3 Groundwater and Surface Water Properties Used in Modeling

Parameter	Unit	Values	Notes/Source
Groundwater			
COI Concentration	mg/L	Constituent specific	Maximum detected concentration in groundwater.
Cross Section Area for the Uppermost Aquifer[a]	m^2	18,330	The sum of the maximum thicknesses of the PMP and the UA (*i.e.*, approximately 7.3 m) multiplied by the length of the ash pond intersecting Newton Lake (*i.e.*, about 2,500 m) (Ramboll, 2021).
Hydraulic Gradient	m/m	0.0048	The average hydraulic gradient determined for the UA was used (Ramboll, 2021).
Hydraulic Conductivity of the Uppermost Aquifer	cm/s	0.00495	Average of the geometric mean horizontal hydraulic conductivities measured for the PMP (3×10^{-3} cm/s) and the UA (6.8×10^{-3} cm/s).
Surface Water			
Surface Water Flow Rate	L/yr	3.37×10^{13}	An overflow dam located in the south portion of the lake (between the two lake arms) regulates water discharge out of the lake. The total discharge rate through the dam is 59,450 cubic feet per second [cfs] (US National Dams, 2022). This flow is assumed to be representative of the sum of discharges from the eastern and western arms of the Lake. A flow rate of 37,701 cfs was determined for the eastern arm adjacent to the PAP based on watershed ratio analysis (Archfield & Vogel, 2010; Gianfagna *et al*., 2015) using the USGS StreamStats application (USGS, 2022).
Total Suspended Solids	mg/L	9.2	Average of TSS concentrations measured at four monitoring locations in Newton Lake (USGS *et al*., 2022).
Depth of the Water Column	m	5.08	Depth of Newton Lake near the power plant (Ramboll, 2021).
Suspended Sediment to Water Partition Coefficient	mg/L	Constituent specific	Values based on US EPA (2014).

Notes:
cfs = Cubic Feet per Second; COI = Constituent of Interest; L/yr = Liter Per Year; m^2 = Square Meter; PAP = Primary Ash Pond; PMP = Primary Migration Pathway; TSS = Total Suspended Solids; UA = Uppermost Aquifer; US EPA = United States Environmental Protection Agency.
(a) Cross-sectional area represents the area through which groundwater flows from the UA into Newton Lake (*i.e.*, the area where groundwater intersects Newton Lake).

Table 3.4 Sediment Properties Used in Modeling

Parameter	Unit	Value	Notes/Source
Sediment			
Depth of Upper Benthic Layer	m	0.03	Default (US EPA, 2014)
Depth of Water Body	m	5.11	Depth of water column (5.08 m, depth of Newton Lake near the power plant (Ramboll, 2021) plus depth of upper benthic layer (0.03 m) (US EPA, 2014)
Bed Sediment Particle Concentration	g/cm^3	1	Default (US EPA, 2014)
Bed Sediment Porosity	-	0.6	Default (US EPA, 2014)
TSS Mass per Unit Area	kg/m^2	0.047	Depth of water column × TSS × conversion factors (10^{-6} kg/mg and 1,000 L/m^3)
Sediment Mass per Unit Area	kg/m^2	30	Depth of upper benthic layer × bed sediment particulate concentration × conversion factors (0.001 kg/g, 10^6 cm^3/m^3)
Sediment to Water Partition Coefficients	mg/L	Constituent specific	Values based on US EPA (2014)

Notes:
TSS = Total Suspended Solids; US EPA = United States Environmental Protection Agency.

Table 3.5 Surface Water and Sediment Modeling Results

COI	Groundwater Concentration (mg/L or pCi/L)	Mass Discharge Rate (mg/year or pCi/year)	Total Water Column Concentration (mg/L or pCi/L)	Concentration Sorbed to Bottom Sediments (mg/kg or pCi/kg)
Total Metals				
Arsenic	0.13	1.8E+07	5.3E-07	1.2E-04
Cadmium	0.0034	4.7E+05	1.4E-08	1.6E-05
Cobalt	0.036	4.9E+06	1.5E-07	1.2E-04
Lead	0.065	8.9E+06	2.7E-07	1.9E-03
Lithium	0.30	4.1E+07	1.2E-06	(a)
Mercury	0.0020	2.7E+05	8.2E-09	2.3E-04
Thallium	0.0036	4.9E+05	1.5E-08	2.6E-07
Radionuclides				
Radium-226+228	15	2.1E+09	6.2E-05	4.3E-01
Other				
Chloride	550	7.6E+10	2.3E-03	(a)
Fluoride	8.2	1.1E+09	3.4E-05	5.3E-03
Sulfate	3,200	4.4E+11	1.3E-02	(a)

Notes:
COI = Constituent of Concern; K_d = Equilibrium Partition Coefficient; pCi/L = PicoCuries Per Liter; pCi/kg = PicoCuries Per Kilogram.
(a) Lithium, chloride, and sulfate do not readily sorb to soil or sediment particles; a K_d value of 0 was used for the modeling.

3.4 Human Health Risk Evaluation

The section below presents the results of the human health risk evaluation for recreators (boaters and anglers) in Newton Lake adjacent to the Site. Risks were assessed using the maximum measured or modeled COIs in surface water.

3.4.1 Recreators Exposed to Surface Water

Screening Exposures: Recreators could be exposed to surface water *via* incidental ingestion and dermal contact while boating. In addition, anglers could consume fish caught in Newton Lake. The maximum measured or modeled COI concentrations in surface water were used as conservative upper-end estimates of the COI concentrations to which a recreator might be exposed directly (incidental ingestion of COIs in surface water while boating) and indirectly (consumption of locally caught fish exposed to COIs in surface water).

Screening Benchmarks: Illinois surface water criteria (IEPA, 2019), known as human threshold criteria (HTC), are based on incidental exposure through contact or ingestion of small volumes of water while swimming or during other recreational activities, as well as the consumption of fish. The HTC values were calculated from the following equation (IEPA, 2019):

$$\mathrm{HTC} = \frac{\mathrm{ADI}}{\mathrm{W} + (\mathrm{F} \times \mathrm{BCF})}$$

where:

HTC = Human health protection criterion in milligrams per liter (mg/L)
ADI = Acceptable daily intake (mg/day)
W = Water consumption rate (L/day)
F = Fish consumption rate (kg/day)
BCF = Bioconcentration factor (L/kg-tissue)

Illinois defines the acceptable daily intake (ADI) as the "maximum amount of a substance which, if ingested daily for a lifetime, results in no adverse effects to humans" (IEPA, 2019). US EPA defines its chronic reference dose (RfD) as an "estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure for a chronic duration (up to a lifetime) to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime" (US EPA, 2011a). Illinois lists methods to derive an ADI from the primary literature (IEPA, 2019). In accordance with Illinois guidance, Gradient derived an ADI by multiplying the MCL by the default water ingestion rate of 2 L/day (IEPA, 2019). In the absence of an MCL, Gradient applied the RfD used by US EPA to derive its Regional Screening Levels (RSLs) (US EPA, 2021b) as a conservative estimate of the ADI. The RfDs are given in mg/kg-day, while the ADIs are given in mg/day; thus, Gradient multiplied the RfD by a standard body weight of 70 kg to obtain the ADI in mg/day. The calculation of the HTC values is shown in Appendix B, Table B.1.

Gradient used bioconcentration factors (BCFs) from a hierarchy of sources. The primary BCFs were those that US EPA used to calculate the National Recommended Water Quality Criteria (NRWQC) for human health (US EPA, 2002). Other sources included BCFs used in the US EPA coal combustion ash risk assessment (US EPA, 2014) and BCFs reported by Oak Ridge National Laboratory's Risk Assessment

Information System (ORNL RAIS) (ORNL, 2020).[5] Lithium did not have a BCF value available from any authoritative source; therefore, the water quality criterion for lithium was calculated assuming a BCF of 1. This is a conservative assumption, as lithium does not readily bioaccumulate in the aquatic environment (ECHA, 2020a,b; ATSDR, 2010).

Illinois recommends a fish consumption rate of 0.020 kg/day (20 g/day) for an adult weighing 70 kg (IEPA, 2019). Illinois recommends a water consumption rate of 0.01 L/day for "incidental exposure through contact or ingestion of small volumes of water while swimming or during other recreational activities" (IEPA, 2019). Appendix B, Table B.1 presents the calculated HTC for fish and water and for fish consumption only.

The HTC for fish consumption for radium-226+228 was calculated as follows:

$$\mathrm{HTC} = \frac{\mathrm{TCR}}{(\mathrm{SF} \times \mathrm{BAF} \times \mathrm{F})}$$

where:

HTC = Human health protection criterion in picoCuries per liter (pCi/L)
TCR = Target cancer risk ($1x10^{-5}$)
SF = Food ingestion slope factor (risk/pCi)
BAF = Bioaccumulation factor (L/kg-tissue)
F = Fish consumption rate (kg/day)

The food ingestion slope factor (lifetime excess total cancer risk per unit exposure, in risk/pCi) used to calculate the HTC was the highest value of those for radium-226 (Ra-226), radium-228 (Ra-228), and "Ra-228+D" (US EPA, 2001). According to US EPA (2001), "+D" indicates that "the risks from associated short-lived radioactive decay products (*i.e.,* those decay products with radioactive half-lives less than or equal to 6 months) are also included."

Screening Risk Evaluation: The maximum modeled and measured COI concentrations in surface water were compared to the calculated Illinois HTC values (Table 3.6). All surface water concentrations were below their respective benchmarks. The HTC values are protective of recreational exposure *via* water and/or fish ingestion and do not account for dermal exposures to COIs in surface water while boating. However, given that the measured and modeled COI surface water concentrations are orders of magnitude below HTC protective of water and/or fish ingestion, dermal exposures to COIs are not expected to be a risk concern. Moreover, the dermal uptake of metals is considered to be minimal and only a small proportion of ingestion exposures. Thus, none of the COIs evaluated would be expected to pose an unacceptable risk to recreators exposed to surface water while boating and anglers consuming fish caught in Newton Lake.

[5] Although recommended by US EPA (2015b), US EPA EpiSuite 4.1 (US EPA, 2019) was not used as a source of BCFs because inorganic compounds are outside the estimation domain of the program.

Table 3.6 Risk Evaluation for Recreators (Boaters and Anglers)

COI	Maximum SW Concentration		HTC for Water and Fish	HTC for Water Only	HTC for Fish Only	COPC	
	Modeled	Measured[a]				Based on Modeled Concentrations	Based on Measured Concentrations
Total Metals (mg/L)							
Arsenic	5.3E-07	4.2E-03	0.022	2.0	0.023	No	No
Cobalt	1.5E-07	ND	0.0035	2.1	0.0035	No	NA
Lead	2.7E-07	ND	0.015	0.015	0.015	No	NA
Lithium	1.2E-06	ND	4.7	14	7.0	No	NA
Thallium	1.5E-08	ND	0.0017	0.40	0.0017	No	NA
Radionuclides (pCi/L)							
Radium-226+228	6.2E-05	2.1E+00	1,000	1,000	87,413	No	No
Other (mg/L)							
Fluoride	3.4E-05	5.1E-01	143	800	174	No	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; HTC = Human Threshold Criteria; NA = Not Applicable; ND = Not Determined; pCi/L = PicoCuries Per Liter; SW = Surface Water.
(a) Measured concentrations are listed only for the constituents identified as COIs. Measured surface water concentrations may be different from modeled concentrations because measured data include the effects of background and other industrial sources. Modeled concentrations only represent the potential effect on surface water quality resulting from the measured groundwater concentrations.

3.4.2 Recreators Exposed to Sediment

Recreational exposure to sediment may occur during boating activity in Newton Lake; exposure to sediment may occur through incidental ingestion and dermal contact.

Screening Exposures: COIs in impacted groundwater flowing into the river can sorb to sediments. In the absence of sediment data, sediment concentrations were modeled using maximum detected groundwater concentrations.

Screening Benchmarks: There are no established recreator RSLs that are protective of recreational exposures to sediment (US EPA, 2021c). Therefore, benchmarks that are protective of recreational exposures to sediment *via* incidental ingestion and dermal contact were calculated using US EPA's RSL guidance (US EPA, 2021c). These benchmarks were calculated using the recommended assumptions (*i.e.*, oral bioavailability, body weights, averaging time) and toxicity reference values (*i.e.*, RfD and cancer slope factor [CSF]). Recreators were assumed to be exposed to sediment while recreating 60 days a year (or two weekend days per week for 30 weeks a year, from April to October). The exposure duration was assumed for a child 6 years of age and an adult 20 years of age, per US EPA guidance (Stalcup, 2014). The daily recommended residential soil ingestion rates of 200 mg/day for a child and 100 mg/day for an adult are based on an all-day exposure to residential soils (Stalcup, 2014; US EPA, 2011b). Since recreational exposures to sediment are assumed to occur for less than four hours per day, one-third of the daily residential soil ingestion (67 mg/day for a child and 33 mg/day for an adult) was used as a conservative assumption. For dermal exposures, recreators were assumed to be exposed to sediment on their lower legs and feet (1,026 cm^2 for the child and 3,026 cm^2 for the adult, based on the age-weighted surface areas reported in US EPA, 2011b). While other body parts may be exposed to sediment, the contact time will likely be very short, as the sediment would wash off in the surface water. Gradient used US EPA's recommended adherence factor of 0.2 mg/cm^2 based on child exposure to wet soil (US EPA, 2004; Stalcup, 2014), which was used in the US EPA RSL User's Guide for a child recreator exposed to soil or sediment

(US EPA, 2021c). The sediment screening benchmarks were calculated based on a target hazard quotient of 1, or a target cancer risk of $1x10^{-5}$. Appendix B, Table B.2 presents the calculation of screening benchmarks protective of recreational exposures to sediment. A recreator sediment screening benchmark for radium-226+228 was based on soil Preliminary Remediation Goals (PRGs) calculated for radium-226 and radium-228 using US EPA's PRG calculator (US EPA, 2020). The lower of the two values was used as the recreator sediment screening benchmark for radium-226+228 (Appendix B, Table B.3).

Screening Risk Evaluation: The modeled sediment concentrations were well below the recreational sediment screening benchmarks (Table 3.7). Therefore, exposure to sediment is not expected to pose an unacceptable risk to recreators while boating.

Table 3.7 Risk Evaluation for Recreators Exposed to Sediment

COI	Modeled Sediment Concentration (mg/kg)	Recreator Sediment Screening Benchmark (mg/kg)	COPC
Total Metals (mg/kg)			
Arsenic	1.2E-04	6.8E+01	No
Cobalt	1.2E-04	4.1E+02	No
Lead	1.9E-03	4.0E+02	No
Lithium	(a)	2.7E+03	NA
Thallium	2.6E-07	1.4E+01	No
Radionuclides (pCi/kg)			
Radium-226+228	4.3E-01	7.9E+03	No
Other (mg/kg)			
Fluoride	5.3E-03	5.5E+04	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; K_d = Equilibrium Partition Coefficient; NA = Not Applicable; pCi/kg = PicoCuries Per Kilogram.
(a) Lithium does not readily sorb to soil or sediment particles; a K_d value of 0 was used for the modeling.

3.5 Ecological Risk Evaluation

Based on the ecological CEM (Figure 3.4), ecological receptors could be exposed to surface water and dietary items (*i.e.*, prey and plants) potentially impacted by identified COIs (cadmium, cobalt, lead, mercury, radium-226+228, chloride, and fluoride).

3.5.1 Ecological Receptors Exposed to Surface Water

Screening Exposures: The ecological evaluation considered aquatic communities in Newton Lake potentially impacted by identified ecological COIs. Measured and modeled surface water concentrations were compared to risk-based ecological screening benchmarks.

Screening Benchmarks: Surface water screening benchmarks protective of aquatic life were obtained from the following hierarchy of sources:

- IEPA SWQS (IEPA, 2019), regulatory standards that are intended to protect aquatic life exposed to surface water on a long-term basis (*i.e.*, chronic exposure). For cadmium, the surface water

benchmark is hardness dependent and calculated using a default hardness of 100 mg/L (US EPA, 2022)[6];

- US EPA Region IV (2018) surface water ESVs for hazardous waste sites; and
- US DOE benchmarks from the guidance document, "A Graded Approach for Evaluating Radiation Doses to Aquatic and Terrestrial Biota" (US DOE, 2019).

Risk Evaluation: The maximum measured and modeled COI concentrations in surface water were compared to the benchmarks protective of aquatic life (Table 3.8). The measured and modeled surface water concentrations for the COIs were below their respective benchmarks. Thus, none of the COIs evaluated are expected to pose an unacceptable risk to aquatic life in Newton Lake.

Table 3.8 Risk Evaluation of Ecological Receptors Exposed to Surface Water

COI	Maximum Surface Water Concentration		Ecological Freshwater Benchmark	Basis	COPC	
	Modeled	Measured			Based on Modeled Concentrations	Based on Measured Concentrations
Total Metals (mg/L)						
Cadmium	1.4E-08	ND	0.0011	IEPA SWQC	No	NA
Cobalt	1.5E-07	ND	0.019	US EPA R4 ESV	No	NA
Lead	2.7E-07	ND	0.020	IEPA SWQC	No	NA

Fluoride	3.4E-05	0.51	4.0	IEPA SWQC	No	No

Notes:
COI = Constituent of Interest; COPC = Constituent of Potential Concern; IEPA SWQC = Illinois Environmental Protection Agency Surface Water Quality Standard; NA = Not Applicable; ND = Not Detected; pCi/L = PicoCuries Per Liter; US DOE = United States Department of Energy; US EPA R4 ESV = United States Environmental Protection Agency Region IV Ecological Screening Value.

3.5.2 Ecological Receptors Exposed to Sediment

Screening Exposures: COIs in impacted groundwater discharging into Newton Lake can sorb to sediments *via* chemical partitioning. In the absence of sediment data, sediment concentrations were modeled using maximum detected groundwater concentrations. Therefore, the modeled COI sediment concentrations reflect the potential maximum Site-related sediment concentration originating from groundwater.

Screening Benchmarks: Sediment screening benchmarks were obtained from US EPA Region IV (2018). The majority of the sediment ESVs are based on threshold effect concentrations (TECs) from MacDonald *et al.* (2000), which provide consensus values that identify concentrations below which harmful effects on sediment-dwelling organisms are unlikely to be observed. In the absence of an ESV for radium-226+228, a sediment screening value of 90,000 pCi/kg was used, based on the biota concentration guide (BCG) for radium-228 (US DOE, 2019).[7] Chloride and fluoride are not expected to sorb to sediment; therefore, risk

[6] Conservatisms associated with using a default hardness value are discussed in Section 3.6.
[7] The biota concentration guide (BCG) for sediment is 90 pCi/g for Ra-228 and 100 pCi/g for Ra-226; the lower of the two values was used for Ra-226+228, and converted to pCi/kg (US DOE, 2019).

to ecological receptors exposed to sediment was not evaluated for these constituents. The benchmarks used in this evaluation are listed in Table 3.9.

Screening Risk Results: The maximum modeled COI sediment concentrations were below their respective sediment screening benchmarks (Table 3.9). The modeled sediment concentrations attributed to potential contributions from Site groundwater for all COIs were less than 1% of the sediment screening benchmark. Therefore, the modeled sediment concentrations attributed to potential contributions from Site groundwater are not expected to significantly contribute to ecological exposures in Newton Lake adjacent to the Site.

Table 3.9 Risk Evaluation of Ecological Receptors Exposed to Sediment

COI	Modeled Sediment Concentration	ESV[a]	COPC	% of Benchmark
Total Metals (mg/kg)				
Cadmium	1.6E-05	0.99	No	0.0016%
Cobalt	1.2E-04	50	No	0.00024%
Lead	1.9E-03	35.8	No	0.0053%
Mercury	2.3E-04	0.18	No	0.13%
Radionuclides (pCi/kg)				
Radium-226+228	4.3E-01	90,000[b]	No	0.00048%
Other (mg/kg)				
Chloride	-	-	-	-
Fluoride	5.3E-03	NA	-	-

(a) ESV from US EPA Region IV (2018).
(b) ESV from US DOE (2019); value converted from 90 pCi/g to 90,000 pCi/kg.

3.5.3 Ecological Receptors Exposed to Bioaccumulative Constituents of Interest

Screening Exposures: COIs with bioaccumulative properties can impact higher-trophic-level wildlife exposed to these COIs *via* direct exposures (surface water and sediment exposure) and secondary exposures through the consumption of dietary items (*e.g.*, plants, invertebrates, small mammals, and fish).

Screening Benchmark: US EPA Region IV (2018) guidance and IEPA SWQS (IEPA, 2019) guidance were used to identify constituents with potential bioaccumulative effects.

Risk Evaluation: With the exception of mercury, the ecological COIs (cadmium, cobalt, lead, radium-226+228, chloride, and fluoride) were not identified as having potential bioaccumulative effects. Therefore, these COIs are not considered to pose an ecological risk *via* bioaccumulation. IEPA (2019) identifies mercury as the only metal with bioaccumulative properties. US EPA Region IV (2018) also identifies mercury (including methyl mercury) as having potential bioaccumulative effects.[8]

The modeled mercury concentration in surface water (8.2×10^{-9} mg/L) was below the mercury surface water ESV for wildlife (1.3×10^{-6} mg/L), and the modeled mercury concentration in sediment (2.3×10^{-4} mg/kg) was below the sediment ESV for wildlife (0.18 mg/kg) (US EPA Region IV, 2018). Both the

[8] US EPA Region IV (2018) identifies selenium as having potential bioaccumulative effects. Although selenium was detected in groundwater, it was not considered an ecological COI.

modeled surface water and sediment concentrations were below benchmarks protective of receptors accounting for bioacccumulative properties. Therefore, in addition to not posing an ecological risk from direct toxicity, mercury does not pose a risk from bioaccumulation exposures.

3.6 Uncertainties and Conservatisms

A number of uncertainties and their potential impact on the risk evaluation are discussed below. Wherever possible, conservative assumptions were used in an effort to minimize uncertainties and overestimate rather than underestimate risks.

Exposure Estimates:

- The risk evaluation included the IL Part 845.600 constituents detected in groundwater samples (above GWPS) collected from wells associated with the PAP. However, it is possible that not all of the detected constituents are related specifically to the PAP.
- The human health and ecological risk characterizations were based on the maximum measured or modeled COI concentrations, rather than on averages. Thus, the variability in exposure concentrations was not considered. Assuming continuous exposure to the maximum concentration overestimates human and ecological exposures, given that receptors are mobile and concentrations change over time. For example, US EPA guidance states that risks should be estimated using average exposure concentrations as represented by the 95% upper confidence limit on the mean (US EPA, 1992). Given that exposure estimates based on the maximum concentrations did not exceed risk benchmarks, Gradient has greater confidence that there is no risk concern.
- Only constituents detected in groundwater were used to identify COIs and model COI concentrations in surface water and sediment. For the constituents that were not detected in PAP groundwater, the detection limits were below the IL Part 845.600 GWPS and thus do not require further evaluation.
- COI concentrations in surface water were modeled using the maximum detected total COI concentrations in groundwater. Modeling surface water concentrations using total metal concentrations may overestimate surface water concentrations because dissolved concentrations, which are lower than total concentrations, represent the mobile fractions of constituents that could likely flow into and mix with surface water.
- The COIs identified in this evaluation also occur naturally in the environment. Contributions to exposure from natural or other non-AP-related sources were not considered in the evaluation of modeled concentrations; only exposure contributions potentially attributable to Site groundwater mixing with surface water were evaluated. While not quantified, exposures from potential PAP-related groundwater contributions are likely to represent only a small fraction of the overall human and ecological exposure to COIs that also have natural or non-AP-related sources.
- Screening benchmarks for human health were developed using exposure inputs based on US EPA's recommended values for reasonable maximum exposure (RME) assessments (Stalcup, 2014). RME is defined as "the highest exposure that is reasonably expected to occur at a site but that is still within the range of possible exposures" (US EPA, 2004). US EPA states the "intent of the RME is to estimate a conservative exposure case (*i.e.*, well above the average case) that is still within the range of possible exposures" (US EPA, 1989). US EPA also notes that this high-end exposure "is the highest dose estimated to be experienced by some individuals, commonly stated as approximately equal to the 90th percentile exposure category for individuals" (US EPA, 2015c). Thus, most individuals will have lower exposures than those presented in this risk assessment.

Toxicity Benchmarks:

- Screening-level ecological benchmarks were compiled from IEPA and US EPA guidance and designed to be protective of the majority of Site conditions, leaving the option for Site-specific refinement. In some cases, these benchmarks may not be representative of the Site-specific conditions or receptors found at the Site, or may not accurately reflect concentration-response relationships encountered at the Site. For example, the ecological benchmark for cadmium is hardness dependent. However, hardness data are not available for Newton Lake; therefore, Gradient relied on US EPA's default hardness of 100 mg/L. Use of a higher hardness value would increase the cadmium SWQS because benchmarks become less stringent with higher levels of hardness. Regardless of the hardness, the maximum modeled cadmium concentration is orders of magnitude below the SWQS.
- In addition, for the ecological evaluation, Gradient conservatively assumed all constituents to be 100% bioavailable. Modeled COI concentrations in surface water are considered total COI concentrations. In addition, the measured surface water data used in this report represent total concentrations. US EPA recommends using dissolved metals as a measure of exposure to ecological receptors because it represents the bioavailable fraction of metal in water (US EPA, 1993). Therefore, the modeled surface water COI concentrations may be an overestimation of exposure concentrations to ecological receptors.
- In general, it is important to appreciate that the human health toxicity factors used in this risk evaluation are developed to account for uncertainties, such that safe exposure levels used as benchmarks are often many times lower (even orders of magnitude lower) than the levels that cause effects that have been observed in human or animal studies. For example, toxicity factors incorporate a 10-fold safety factor to protect sensitive subpopulations. This means that a risk exceedance does not necessarily equate to actual harm.

4 Summary and Conclusions

A screening-level risk evaluation was performed for Site-related constituents in groundwater at the NPP in Newton, Illinois. The CSM developed for the Site indicates that groundwater beneath the PAP flows into Newton Lake adjacent to the Site and may potentially impact surface water and sediment.

CEMs were developed for human and ecological receptors. The complete exposure pathways for humans include recreators (boaters) in Newton Lake who are exposed to surface water and sediment, and anglers who consume locally caught fish. Based on the local hydrogeology, residential exposure to groundwater used for drinking water or irrigation is not a complete pathway and was not evaluated. The complete exposure pathways for ecological receptors include aquatic life (including aquatic and marsh plants, amphibians, reptiles, and fish) exposed to surface water; benthic invertebrates exposed to sediment; and avian and mammalian wildlife exposed to bioaccumulative COIs in surface water, sediment, and dietary items.

Groundwater data collected from 2015 to 2021 were used to estimate exposures. Surface water data collected from Newton Lake were also evaluated. For groundwater constituents retained as COIs, surface water and sediment concentrations were modeled using the maximum detected groundwater concentration. Surface water and sediment exposure estimates were screened against benchmarks protective of human health and ecological receptors for this risk evaluation.

US EPA has established acceptable risk metrics. Risks above these US EPA-defined metrics are termed potentially "unacceptable risks". Based on the evaluation presented in this report, no unacceptable risks to human or ecological receptors resulting from CCR exposures associated with the PAP were identified. This means that the risks from the Site are likely indistinguishable from normal background risks. Specific risk assessment results include the following:

- For recreators exposed to surface water, all COIs were below the conservative risk-based screening benchmarks. Therefore, none of the COIs evaluated in surface water are expected to pose an unacceptable risk to recreators in Newton Lake adjacent to the Site.
- For recreators exposed to sediment *via* incidental ingestion and dermal contact, the modeled sediment concentrations were below health-protective sediment benchmarks. Therefore, the modeled sediment concentrations are not expected to pose an unacceptable risk to recreators exposed to sediment in Newton Lake adjacent to the Site.
- For anglers consuming locally caught fish, the modeled concentrations of all COIs in surface water (as well as the measured data) were below conservative benchmarks protective of fish consumption. Therefore, none of the COIs evaluated are expected to pose an unacceptable risk to recreators consuming fish caught in Newton Lake.
- Ecological receptors exposed to surface water include aquatic and marsh plants, amphibians, reptiles, and fish. The risk evaluation showed that none of the modeled or measured COIs in surface water exceeded protective screening benchmarks. Ecological receptors exposed to sediment include benthic invertebrates. The modeled sediment COIs did not exceed the conservative screening benchmarks; therefore, none of the COIs evaluated in sediment are expected to pose an unacceptable risk to ecological receptors.

- Ecological receptors were also evaluated for exposure to bioaccumulative COIs. This evaluation considered higher-trophic-level wildlife with direct exposure to surface water and sediment and secondary exposure through the consumption of dietary items (*e.g.*, plants, invertebrates, small mammals, fish). Mercury was the only ecological COI identified as having potential bioaccumulative effects. However, the modeled concentrations did not exceed benchmarks protective of bioaccumulative effects. Therefore, mercury is not considered to pose an ecological risk *via* bioaccumulation. Overall, this evaluation demonstrated that none of the COIs evaluated are expected to pose an unacceptable risk to ecological receptors.

It should be noted that this evaluation incorporates a number of conservative assumptions that tend to overestimate exposure and risk. The risk evaluation was based on the maximum detected COI concentration; however, US EPA guidance states that risks should be based on a representative average concentration such as the 95% upper confidence limit on the mean; thus, using the maximum concentration tends to overestimate exposure. Although the COIs identified in this evaluation also occur naturally in the environment, the contributions to exposure from natural background sources and nearby industry were not considered; thus, CCR-related exposures were likely overestimated. Exposure estimates assumed 100% metal bioavailability, which likely results in overestimates of exposure and risks. Exposure estimates were based on inputs to evaluate the "reasonable maximum exposure"; thus, most individuals will have lower exposures than those estimated in this risk assessment.

Finally, it should be noted that because current conditions do not present a risk to human health or the environment, there will also be no unacceptable risk to human health or the environment for future conditions when the PAP is closed. For all future closure scenarios, potential releases of CCR-related constituents will decline over time and, consequently, potential exposures to CCR-related constituents in the environment will also decline.

Appendix A

Surface Water and Sediment Modeling

Gradient modeled concentrations in river surface water and sediment based on available groundwater data. First, Gradient estimated the flow rate of constituents of interest (COIs) that may flow into Newton Lake *via* groundwater. Then, Gradient adapted United States Environmental Protection Agency's (US EPA's) indirect exposure assessment methodology (US EPA, 1998) in order to model surface water and sediment water concentrations in Newton Lake.

Model Overview

Groundwater flow into Newton Lake is represented by a one-dimensional steady-state model. In this model, the groundwater plume migrates horizontally in the Uppermost Aquifer (UA) and the potential migration pathway (PMP) prior to discharging into Newton Lake. The groundwater flow entering the lake is the flow going through a cross-sectional area with a length equal to the length of the lake adjacent to the Primary Ash Pond (PAP) with potential CCR-related impacts and a height equal to the maximum saturated thicknesses of the UA and the PMP. This is a conservative assumption because groundwater elevation data indicate that only groundwater on the eastern side of the PAP has potential to interact with surface water in the lake. It was assumed that groundwater flowing through the shallow water bearing zones (*i.e.*, the UA and the PMP) may flow into Newton Lake. The length of the groundwater discharge zone was estimated using Google Earth Pro (Google LLC, 2022).

Groundwater flow into Newton Lake mixes with the surface water in the lake. The COIs entering the lake *via* groundwater can dissolve into the water column, sorb to suspended sediments, or sorb to benthic sediments. Using US EPA's indirect exposure assessment methodology (US EPA, 1998), the model evaluates the surface water and sediment concentrations at a location downstream of the groundwater discharge, assuming a well-mixed water column.

Groundwater Discharge Rate

The groundwater discharge rate was evaluated using conservative assumptions. Gradient conservatively assumed that the groundwater concentrations were uniformly equal to the maximum detected concentration for each individual COI. Gradient ignored adsorption by subsurface soil and assumed that groundwater flowing through the shallow aquifers was discharged into the lake.

For each groundwater unit, the groundwater flow rate into the river was derived using Darcy's Law:

$$Q = KiA$$

where:

Q = Groundwater flow rate (m^3/s)
K = Hydraulic conductivity (m/s)
i = Hydraulic gradient (m/m)
A = Cross-sectional area (m^2)

For each COI, the mass discharge rate into the lake was then calculated by:

$$m_c = C_c \times Q \times CF$$

where:

m_c = Mass discharge rate of the COI (mg/year)
C_c = Maximum groundwater concentration of the COI (mg/L)
Q = Groundwater flow rate (m^3/s)

CF = Conversion factors: 1,000 L/m^3; 31,557,600 s/year

The values of the aquifer parameters used for these calculations are provided in Table A.1. The calculated mass discharge rates were then used as inputs for the surface water and sediment partitioning model.

The cross-sectional area for the shallow aquifers was 18,330 m^2. The length of the discharge zone was estimated to be approximately 2,500 m. The height of the discharge zone was assumed to be the sum of the maximum thicknesses of the PMP and the UA (*i.e.*, approximately 7.3 m) (Ramboll, 2021).

The hydraulic gradient was 0.0048 m/m, based on the average horizontal hydraulic gradient determined for the UA (Ramboll, 2021). Hydraulic gradient was not measured in the PMP.

The hydraulic conductivity was 0.00495 cm/s, based on the average of the geometric mean horizontal hydraulic conductivities measured for the PMP (3 x 10^{-3} cm/s) and the UA (6.8 x 10^{-3} cm/s) (Ramboll, 2021).

Surface Water and Sediment Concentration

Groundwater that flows into the lake will be diluted in the surface water flow. Constituents transported by groundwater into the surface water migrate into the water column and the bed sediments. The surface water model Gradient used to estimate the surface water and sediment concentrations is a steady-state model described in US EPA's indirect exposure assessment methodology (US EPA, 1998), and also used in US EPA's "Human and Ecological Risk Assessment of Coal Combustion Residuals" (US EPA, 2014). This model describes the partitioning of constituents between surface water, suspended sediments, and benthic sediments based on equilibrium partition coefficients. It estimates the concentrations of constituents in surface water, suspended sediments, and benthic sediments at steady-state equilibrium at a theoretical location downstream of the discharge point after complete mixing of the water column. In the analysis, Gradient used the partitioning coefficients given in Table J-1 of the US EPA CCR Risk Assessment for all COIs (US EPA, 2014). These coefficients are presented in Table A.2.

To be conservative, Gradient assumed that the constituents were not affected by dissipation or degradation once they entered the water body. The total water body concentration of the COI was calculated as (US EPA, 1998):

$$C_{wtot} = \frac{m_c}{V_f \times f_{water}}$$

where:

C_{wtot} = Total water body concentration of the constituent (mg/L)
m_c = Mass discharge rate of the COI (mg/year)
V_f = Water body annual flow (L/year)
f_{water} = Fraction of COI in the water column (unitless)

Newton Lake was formed by damming and is used as a cooling water supply for Newton Power Plant (NPP) (US National Dams, 2022). Water is drawn from the eastern arm near the power plant and thermal effluent is released at two locations in the western arm *via* NPDES permitted outfalls (IEPA, 2016). A small overflow dam located in the south portion of the lake (between the two lake arms) regulates water discharge out of the lake. The total discharge rate of 59,450 cubic feet per second (cfs) through the overflow dam (US National Dams. 2022) is assumed to be representative of the sum of discharges from the eastern and western arms of the Newton Lake. A flow rate of 37,701 cfs was determined for the eastern arm based on watershed ratio analysis (Archfield & Vogel, 2010; Gianfagna *et al.*, 2015) using the USGS StreamStats application (USGS, 2022). The surface water parameters are presented in Table A.3.

The fraction of COIs in the water column was calculated for each COI using the sediment/water and suspended solids/water partition coefficients (US EPA, 2014, Table J-1). The fraction of COIs in the water column is defined as (US EPA, 2014):

$$f_{water} = \frac{(1 + [K_{dsw} \times TSS \times 0.000001]) \times \frac{d_w}{d_z}}{\left([1 + (K_{dsw} \times TSS \times 0.000001)] \times \frac{d_w}{d_z}\right) + ([bsp + K_{dbs} \times bsc] \times \frac{d_b}{d_z})}$$

where:

K_{dsw}	=	Suspended sediment-water partition coefficient (mL/g)
K_{dbs}	=	Sediment-water partition coefficient (mL/g)
TSS	=	Total suspended solids in the surface water body (mg/L), set equal to 9.2 mg/L, which is the average of TSS concentrations measured at four monitoring locations at Newton Lake (*i.e.*, IL_EPA_WQX-RCR-1, IL_EPA_WQX-RCR-2, IL_EPA_WQX-RCR-3, and IL_EPA_WQX-RCR-4) (USGS *et al*., 2022)
0.000001	=	Units conversion factor
d_w	=	Depth of the water column (m). The depth of the water column was estimated as 5.08 m, based on the geologic cross-section in Ramboll (2021 Figure 2-7). .
d_b	=	Depth of the upper benthic layer (m), set equal to 0.03 m (US EPA, 2014)
$d_z = d_w + d_b$	=	Depth of the water body (m) = 5.11 m
bsp	=	Bed sediment porosity (unitless), set equal to 0.6 (US EPA, 2014)
bsc	=	Bed sediment particle concentration (g/cm^3), set equal to 1.0 g/cm^3 (US EPA, 2014)

The fraction of COIs dissolved in the water column (f_d) is calculated as (US EPA 2014):

$$f_d = \frac{1}{1 + K_{dsw} \times TSS \times 0.000001}$$

The values of the fraction of COIs in the water column and other calculated parameters are presented in Table A.4.

The total water column concentration (C_{wcTot}) of the COIs, comprising both the dissolved and suspended sediment phases, is then calculated as (US EPA, 2014):

$$C_{wcTot} = C_{wtot} \times f_{water} \times \frac{d_z}{d_w}$$

Finally, the dissolved water column concentration (C_{dw}) for the COIs is calculated as (US EPA, 2014):

$$C_{dw} = f_d \times C_{wcTot}$$

The dissolved water column concentration was then used to calculate the concentration of COIs sorbed to suspended solids in the water column (US EPA, 1998):

$$C_{sw} = C_{dw} \times K_{dsw}$$

where:

C_{sw} = Concentration sorbed to suspended solids (mg/kg)
C_{dw} = Concentration dissolved in the water column (mg/L)
K_{dsw} = Suspended solids/water partition coefficient (mL/g)

In the same way, using the total water body concentration and the fraction of COIs in the benthic sediments, the model derives the total concentration in benthic sediments (US EPA, 2014, Table J-1-12):

$$C_{bstot} = f_{benth} \times C_{wtot} \times \frac{d_z}{d_b}$$

where:

C_{bstot} = Total concentration in bed sediment (mg/L or g/m^3)
C_{wtot} = Total water body concentration of the constituent (mg/L)
f_{benth} = Fraction of contaminant in benthic sediments (unitless)
d_b = Depth of the upper benthic layer (m)
$d_z = d_w + d_b$ = Depth of the water body (m)

This value can be used to calculate dry weight sediment concentration as follows:

$$C_{sed-dw} = \frac{C_{bstot}}{bsc}$$

where:

C_{sed-dw} = Dry weight sediment concentration (mg/kg)
C_{bstot} = Total sediment concentration (mg/L)
bsc = Bed sediment bulk density (default value of 1 g/cm^3 from US EPA, 2014)

The total sediment concentration is composed of the concentration dissolved in the bed sediment pore water (equal to the concentration dissolved in the water column) and the concentration sorbed to benthic sediments (US EPA, 1998).

The concentration sorbed to benthic sediments was calculated from (US EPA, 1998):

$$C_{sb} = C_{dbs} \times K_{dbs}$$

where:

C_{sb} = Concentration sorbed to bottom sediments (mg/kg)
C_{dbs} = Concentration dissolved in the sediment pore water (mg/L)
K_{dbs} = Sediments/water partition coefficient (mL/kg)

For each COI, the modeled total water column concentration, the modeled dry weight sediment concentration, and the modeled concentration sorbed to sediment are presented in Table A.5.

Table A.1 Parameters Used to Estimate Groundwater Discharge to Surface Water

Groundwater Unit	Parameter	Name	Value	Unit
Uppermost Aquifer and Potential Migration Pathway	A	Cross-Sectional Area[a]	18,330	m^2
Uppermost Aquifer and Potential Migration Pathway	i	Hydraulic Gradient[b]	0.0048	m/m
Uppermost Aquifer and Potential Migration Pathway	K	Hydraulic Conductivity[c]	0.00495	cm/s

Notes:
Source: Hydraulic gradient and hydraulic conductivity values from Ramboll (2021).
Cross-sectional area was estimated from Ramboll (2021).
(a) The sum of the maximum thicknesses of the PMP and the UA (i.e., approximately 7.3 m) multiplied by the length of the ash pond intersecting Newton lake (*i.e.*, about 2,500 m).
(b) Hydraulic gradient measurements are not available for the PMP. The average hydraulic gradient determined for the UA was used.
(c) Average of the geometric mean horizontal hydraulic conductivities measured for the PMP (3×10^{-3} cm/s) and the UA (6.8×10^{-3} cm/s).

Table A.2 Partition Coefficients

Constituent	Sediment-Water, Mean, K_{dbs}		Suspended Sediment-Water, Mean, K_{dsw}	
	Value (log_{10}) (mL/g)	Value (mL/g)	Value (log_{10}) (mL/g)	Value (mL/g)
Metals				
Arsenic	2.4	2.51E+02	3.9	7.94E+03
Cadmium	3.3	2.00E+03	4.9	7.94E+04
Cobalt	3.1	1.26E+03	4.8	6.31E+04
Lead	4.6	3.98E+04	5.7	5.01E+05
Lithium	-	-	-	-
Mercury	4.9	7.94E+04	5.3	2.00E+05
Thallium	1.3	2.00E+01	4.1	1.26E+04
Radionuclides				
Radium-226+228	-	7.40E+03	-	7.40E+03
Other				
Chloride	-	-	-	-
Fluoride	2.2	1.58E+02	2.2	1.58E+02
Sulfate	-	-	-	-

Notes:
Source: US EPA (2014).
Lithium, chloride, and sulfate do not readily sorb to soils and sediments. Consequently, sediment concentrations were not modeled for these constituents (K_d was assumed to be 0).

Table A.3 Surface Water Parameters

Parameter	Name	Value	Unit
TSS	Total Suspended Solids	9.2	mg/L
V_{fx}	Surface Water Flow Rate	3.37×10^{13}	L/yr
d_b	Depth of Upper Benthic Layer (default)	0.03	m
d_w	Depth of Water Column	5.08	m
d_z	Depth of Water Body	5.11	m
bsc	Bed Sediment Bulk Density (default)	1	g/cm^3
bsp	Bed Sediment Porosity (default)	0.6	-
M_{TSS}	TSS Mass per Unit Area[a]	0.047	kg/m^2
M_S	Sediment Mass per Unit Area[b]	30	kg/m^2

Notes:
Source of default values: US EPA (2014).
Source of TSS data: USGS *et al*., 2022.
(a) Determined by multiplying total suspended solids, TSS by the depth of water column, d_w.
(b) Determined by multiplying depth of upper benthic layer, d_b, with sediment bed particle concentration of 1 g/cc.

Table A.4 Calculated Parameters

COI	Fraction of Constituent in the Water Column f_{water}	Fraction of Constituent in the Benthic Sediments $f_{benthic}$	Fraction of Constituent Dissolved in the Water Column $f_{dissolved}$
Arsenic	0.419	0.581	0.932
Cadmium	0.1280	0.8720	0.5778
Cobalt	0.175	0.825	0.633
Lead	0.023	0.977	0.178

Other				
Chloride	550	7.6E+10	2.3E-03	(a)
Fluoride	8.2	1.1E+09	3.4E-05	5.3E-03
Sulfate	3,200	4.4E+11	1.3E-02	(a)

Notes:

COI = Constituent of Interest; pCi/kg = PicoCuries Per Kilogram; pCi/L = PicoCuries Per Liter.

(a) Lithium, chloride, and sulfate do not readily sorb to soil or sediment particles; a K_d value of 0 was used for the modeling.

Appendix B

Screening Benchmarks

Table B.1 Calculated Water Quality Standards Protective of Incidental Ingestion and Fish Consumption

Human Health COI	BCF[a] (L/kg-tissue)	Basis	MCL (mg/L)	RfD (mg/kg-day)	ADI[b] (mg/day)	Human Threshold Criteria		
						Water & Fish (mg/L)	Water Only (mg/L)	Fish Only (mg/L)
Arsenic	44	NRWQC (2002)	0.010	0.00030	0.020	0.022	2.0	0.023
Cobalt	300	ORNL (2020)	NC	0.00030	0.021	0.0035	2.1	0.0035
Fluoride	2.3	US EPA (2014)	4.0	0.040	8.0	143	800	174
Lead	46	US EPA (2014)	0.015	NC	0.030	0.015	0.015	0.015
Lithium	1	(c)	NC	0.002	0.14	4.7	14	7.0
Thallium	116	NRWQC (2002)	0.0020	0.000010	0.0040	0.0017	0.40	0.0017

Human Health COI	BAF (L/kg-tissue)		MCL (pCi/L)	ADI (pCi/day)	Food Ingestion Slope Factor[d] (risk/pCi)	Human Threshold Criteria		
	SW-Fish	Basis				Water & Fish (pCi/L)	Water Only (pCi/L)	Fish Only (pCi/L)
Radium-226 + 228	4.0	ORNL (2020)	5	10	1.43E-09	1,000	1,000	87,413

Notes:

ADI = Acceptable Daily Intake; BAF = Bioaccumulation Factor; BCF = Bioconcentration Factor; MCL = Maximum Contaminant Level; NC = No Criterion Available; NRWQC = National Recommended Water Quality Criteria; ORNL = Oak Ridge National Laboratory; pCi = picocurie; Ra = Radium; RAIS = Risk Assessment Information System; RfD = Reference Dose; US EPA = United States Environmental Protection Agency.

(a) BCFs from the following hierarchy of sources:

NRWQC (US EPA, 2002). National Recommended Water Quality Criteria: 2002. Human Health Criteria Calculation Matrix.

US EPA (2014). Human and Ecological Risk Assessment of Coal Combustion Residuals.

ORNL RAIS (ORNL, 2020). Risk Assessment Information System (RAIS) Toxicity Values and Chemical Parameters.

(b) ADI based on the MCL is calculated as the MCL (mg/L) multiplied by a water ingestion rate of 2 L/day. In the absence of an MCL, the ADI was calculated as the RfD (mg/kg-day) multiplied by the body weight (70 kg).

(c) BCF of 1 was used as a conservative assumption, due to lack of published BCF.

(d) Food ingestion slope factors for Ra-226+D and Ra-228+D were compared and the higher factor (Ra-228+D) was selected. The "+D" indicates that the risks from "associated short-lived radioactive decay products are also included" (US EPA, 2001).

Equations from IEPA (2019):

Consumption of Water and Fish

$$HTC = \frac{ADI}{W + (F \times BCF)}$$

Incidental Consumption of Water Only

$$HTC = \frac{ADI}{W}$$

Consumption of Fish Only

$$HTC = \frac{ADI}{F \times BCF}$$

Where:

Human Threshold Criteria (HTC)	Chemical-specific	mg/L
Acceptable Daily Intake (ADI)	Chemical-specific	mg/day
Fish Consumption Rate (F)	0.02	kg/day
Bioconcentration Factor (BCF)/ Bioaccumulation Factor (BAF)	Chemical-specific	L/kg-tissue
Water Consumption Rate (W)	0.01	L/day
Body Weight	70	kg
Target Cancer Risk (TCR)	1.0E-05	

Radium-226+228

$$HTC = \frac{TCR}{(SF \times BAF \times F)}$$

1. INTRODUCTION AND BACKGROUND

1.1 Plant and Site Information

Illinois Power Generating Company (IPGC) is the owner of the active coal-fired Newton Power Plant (NPP), also referred to as the Newton Power Station (NEW), in Newton, Illinois. IPGC intends to complete groundwater corrective action at the coal combustion residuals (CCR) surface impoundment (SI) Primary Ash Pond (PAP), which is identified by Illinois Environmental Protection Agency (IEPA) identification (ID) number (No.) W0798070001-01, CCR Unit ID 501, and National Inventory of Dams (NID) No. IL50719. Groundwater corrective action for the PAP will be performed under the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845, Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments [1] and the requirements of Title 40 of the Code of Federal Regulations (40 C.F.R.) § 257, herein referred to as the Federal CCR Rule [2].

1.2 CAAA-SIR Background and Scope

35 I.A.C. § 845 requires a Corrective Action Alternatives Analysis (CAAA) to be completed as part of remedy selection, pursuant to the requirements of 35 I.A.C. § 845.670(e). The CAAA for the NEW PAP was prepared by Gradient Corporation (Gradient). Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Corrective Action Alternatives Analysis Supporting Information Report (CAAA-SIR) to provide information requested by Gradient to support the CAAA for the NEW PAP.

This CAAA-SIR was prepared to address specific constituents of concern (COC) where exceedances of the 35 I.A.C. § 845.600 groundwater protection standards (GWPS) have been detected in the PAP's groundwater compliance monitoring wells. The COCs with exceedances[1] addressed by this CAAA-SIR, as of the 2024 Annual Report [3], include lithium, sulfate, and total dissolved solids (TDS).

This CAAA-SIR is a feasibility-level assessment utilized to evaluate multiple groundwater corrective action alternatives. The remedy that is ultimately selected within the CAAA, to which this CAAA-SIR is attached, was then further developed into a permit-level remedy within the Corrective Action Plan (CAP), to which the CAAA is attached. Therefore, there may be minor differences in information presented for the selected remedy between this CAAA-SIR and the CAP. Information that may be different includes, but is not limited to, groundwater quality data, groundwater modeling inputs and results, implementation schedules, time to reach GWPS, and the physical dimensions and scope of the remedy, and engineering design parameters. These differences are due to the further remedy refinement that is inherent with advancing the selected alternative into the permit-level remedy that is included within the CAP.

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or GWPSs as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 25, 2021 as part of IPGC's operating permit application for the NPP PAP. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, IPGC has not identified any actual exceedances.

1.2.1 Identified Corrective Action Alternatives

Corrective action remedies selected for evaluation within this CAAA-SIR were identified as potentially feasible for the PAP in the Corrective Measures Assessment (CMA), prepared by Ramboll and attached to the CAAA prepared by Gradient. The remedies identified as potentially feasible included:

- Alternative 1: Source control with groundwater polishing (GWP); and
- Alternative 2: Source control with groundwater extraction trenches (GWET).

Other remedies, including source control with cutoff wall and source control with *in-situ* chemical treatment, were determined to be infeasible for the site during the CMA process.

1.2.2 Scope of CAAA-SIR

Ramboll completed the following tasks and documented the tasks within this CAAA-SIR, for each of the corrective action alternative remedies listed in **Section 1.2.1**:

- Feasibility-level design drawings were developed to show the approximate extents and typical sections/details of the Alternative 2 remedy, source control with GWET, (**Appendix A**). Drawings were not prepared for the Alternative 1 remedy as it does not involve construction at the site.
- Narratives describing the implementation of each remedy were developed, including the pre-design, design, construction, operations, and maintenance (O&M), and closeout phases.
- Feasibility-level schedules providing the estimated time to implement the remedy were developed, including design, permitting, construction, and post-construction O&M.
- Feasibility-level plans for the management of extracted groundwater were developed for the Alternative 2 remedy that include the generation of extracted groundwater.
- Information required to evaluate specific portions of 35 I.A.C. § 845.670(e) requirements were prepared, as requested by Gradient, including 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3).
- Estimates of implementation-based equipment mileage, vehicle delivery mileage, labor hour, and labor commuting mileage, were developed for each remedy alternative where physical construction and/or O&M activities are expected to occur.

All remedies presented within this CAAA-SIR assume that the source control presented in the Final Closure Plan [4] for the PAP, and the subsequent update that was submitted to IEPA in 2025 [5] would also be implemented. Source control is the primary corrective action for the PAP and would include removing free liquids from the CCR and completing a hybrid closure-in-place (CIP). This includes consolidating the current PAP footprint from 404 acres down to 252.3 acres (the CIP area), in accordance with the 2025 update to the closure plan [5] and installing a geomembrane final cover system.

Updated groundwater modeling (**Appendix B1**) estimates that source control alone would result in GWPS being achieved approximately 34 years after closure completion (**Appendix B1**) without implementing other forms of corrective action. The potential remedies evaluated in this CAAA-SIR are intended to work in conjunction with the primary remedy, which is source control.

1.2.3 Criterion for Estimating Time to Achieve GWPS

Times to achieve GWPS for each of the remedial alternative remedies were estimated using 26 PAP monitoring wells in the vicinity of the proposed corrective action alternatives with average observed sulfate concentrations exceeding the GWPS of 400 milligrams per liter (mg/L).

1.3 Report Contents

The following information is included within this report:

- **Section 1** includes the introduction and background;
- **Section 2** includes information for the Alternative 1 Remedy: Source control with GWP;
- **Section 3** includes information for the Alternative 2 Remedy: Source control with GWET,
- **Section 4** includes information used to develop estimates of material quantities, labor hours, and mileage; and
- **Section 5** includes reference documents used in the development of this CAAA-SIR.

2. ALTERNATIVE 1 REMEDY: SOURCE CONTROL WITH GROUNDWATER POLISHING

The Alternative 1 remedy, source control with GWP, would include a consolidate-and-cap approach for source control, after which GWP would be implemented. GWP is a remedial alternative that relies on natural geochemical processes and may be appropriate as recognized by the United States Environmental Protection Agency (USEPA) in a final policy directive for groundwater remediation [6].

2.1 Supporting Groundwater Modeling and Time to Reach GWPS

The COCs exceeding the GWPS at compliance groundwater monitoring wells as of the 2024 Annual Report [3] are lithium, sulfate, and TDS. Sulfate was selected for modeling the source control presented in the Final Closure Plan and was identified as a surrogate for the exceedances of lithium and TDS, as described in the Groundwater Modeling Report [7] (included in **Appendix B2**) and subsequent update prepared to support the revised closure plan [5]. For modeling purposes, it was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]) which is a conservative estimate for predicting contaminant transport times in the model. Sulfate transport is likely to be affected by both chemical and physical attenuation mechanisms (*i.e.*, adsorption and/or precipitation reactions as well as dilution and dispersion). Physical attenuation (dilution and dispersion) of contaminants in groundwater is simulated in the groundwater computer models. Chemical attenuation mechanisms and their effect on modeled times for exceedances to reach the GWPS are discussed in the Groundwater Polishing Evaluation Report [8] and summarized herein.

Groundwater modeling for the Alternative 1 remedy, performed to support the revised closure plan and CAAA-SIR (**Appendix B**), estimated that GWPS would be met in 34 years after the implementation of source control for all wells within the existing PAP monitoring well network.

2.2 Remedy Implementation

Implementation of this portion of the remedy would be initiated after source control (*e.g.,* final closure of the PAP) is completed. Implementation would include performing corrective action groundwater monitoring, enacting an adaptive management strategy, and, after GWPS have been met, performing corrective action closure and completion activities. Information associated with each of these activities is described below.

- Corrective Action Groundwater Monitoring
  - Regular corrective action groundwater monitoring would be conducted utilizing a corrective action groundwater monitoring network designed in accordance with 35 I.A.C. § 845.680(c), which specifies that wells must be installed in the plume of contamination that lies beyond the waste boundary.
    - Samples will be collected for major ions for evaluating groundwater chemistry and COCs. Samples will be collected on a quarterly basis initially and potentially reduced to a semiannual basis once five years of monitoring have occurred, in accordance with 35 I.A.C. 845.650(b)(4).

  - Monitoring results would be submitted to IEPA for each monitoring event, in addition to an annual groundwater monitoring and corrective action report, in accordance with 35 I.A.C. 845.610(e).
  - Routine maintenance of the monitoring well system would occur during the monitoring period. This would include inspecting the wells, making repairs to the wells (as and if needed), and rehabilitating and/or replacing wells to improve performance (as and if needed).

- Adaptive Management during Monitoring
  - Groundwater monitoring results would be evaluated and documented in in the monitoring reports submitted to IEPA, in accordance with 35 I.A.C. 845.610(e)
  - Remedy progress evaluation as part of adaptive site management may include additional investigation to inform updates to the CSM, groundwater, and geochemical models.
  - If remedy progress does not correspond with expectations, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. 845.680(b).
- Corrective Action Confirmation Monitoring and Completion
  - After GWPS have been met for all corrective action monitoring wells, corrective action confirmation groundwater monitoring would be implemented. This would include monitoring each well for three additional years to confirm that GWPS have been achieved, in accordance 35 I.A.C. 845.680(c).
    - It should be noted that post-closure care groundwater monitoring required fora 30-year period by 35 I.A.C. 845.780(c) will continue to occur after corrective action groundwater monitoring is expected to be completed.
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification would be prepared and submitted to IEPA, in accordance with 35 I.A.C. 845.680(e).

2.2.1 Remedy Implementation Schedule

A feasibility-level implementation schedule for the Alternative 1 source control with GWP remedy is provided in **Table A** below.

Table A. Feasibility-Level Implementation Schedule – Alternative 1: Source Control with GWP

Implementation Phase	Implementation Task	Timeframe* (Preliminary Estimates)
Corrective Action Implementation	Corrective Action Monitoring (Time to Meet GWPS)	408 months
	Corrective Action Confirmation Monitoring	36 months
	Corrective Action Completion	6 months
	Timeframe to Complete Corrective Action Implementation	450 months
	Total Timeline to Complete Corrective Action (after completion of source control)	450 months (37.5 years)

*All timeframes are assumed to start after source control (*e.g.,* final closure of the SI) is complete and a corrective action permit has been issued by IEPA, whichever is later.

2.2.2 Management of Extracted Groundwater

No groundwater extraction would occur under this remedy.

2.2.3 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) Information

As requested by Gradient, the following information required by 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) has been developed for the remedy. The information was developed based on preliminary-level information contained within the CMA for the NEW PAP and then refined based on additional feasibility-level design activities performed as part of the development of this CAAA-SIR.

- Potential Need for Replacement of the Remedy – 35 I.A.C. § 845.670(e)(1)(H)
  - No replacement of the remedy would be required for source control with GWP, as a physical remedy would not be constructed.
- Degree of Difficulty Associated with Constructing the Remedy – 35 I.A.C. § 845.670(e)(3)(A)
  - No construction would be required with the source control with GWP remedy; therefore, there is no difficulty in construction of the remedy.
- Expected Operational Reliability of the Remedy - 35 I.A.C. § 845.670(e)(3)(B)
  - As documented in the Groundwater Polishing Evaluation Report [8], groundwater geochemical processes anticipated to occur as downgradient groundwater approaches ambient background conditions are not expected to alter the chemical mechanisms of GWPS and are not expected to delay the modeled time to achieve GWPS compliance.
  - GWP will begin once source control has been completed without delays and continuously function during the corrective action period.
- Need to Coordinate with and Obtain Necessary Approvals and permits from Other Agencies - 35 I.A.C. § 845.670(e)(3)(C)
  - No permits from other agencies would be required outside of permits issued by IEPA for source control (Final Closure Plan and Construction Permit Application, submitted to IEPA in 2022 and subsequently revised in 2025 [4, 5]).
- Availability of Necessary Equipment and Specialists - 35 I.A.C. § 845.670(e)(3)(D)
  - Equipment and specialists for field data collection and groundwater sampling are required for the GWP alternative. Laboratory equipment and specialists would also be required to assess groundwater concentrations of site constituents. Groundwater professionals (*i.e.,* geologists, hydrogeologists, statisticians, geochemists) would be required to perform statistical analysis and other assessments to confirm that GWP is functioning as-intended and prepare corrective-action related groundwater monitoring and progress reports.
  - The equipment and specialists required for site groundwater monitoring and analysis are currently performing this work as part of the routine groundwater monitoring program in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring for this alternative.
- Available Capacity and Location of Needed Treatment, Storage, and Disposal Services – 35 I.A.C. § 845.670(e)(3)(E)
  - No treatment, storage, or disposal services would be required with the source control with GWP remedy, as GWP would not generate any appreciable volume of waste or wastewater.

3. ALTERNATIVE 2 REMEDY: SOURCE CONTROL WITH GROUNDWATER EXTRACTION TRENCHES

The Alternative 2 remedy, source control with groundwater extraction trenches (GWETs), includes the construction of two downgradient GWETs that would be constructed in conjunction with source control (*e.g.*, final closure) implementation. Each trench is described below:

- East Trench
  - The east trench would be located in the vicinity of APW10 to address impacts of TDS at APW04 and APW12 and sulfate at APW04 and APW10.
  - The east trench would extend from grade surface to approximately 30 feet below ground surface (bgs) to an approximate elevation[2] of 503 feet, in order to capture impacted groundwater in the uppermost aquifer (UA) and potential migration pathway (PMP).
  - The east trench would have a total length of approximately 2,000 feet, extending along the exterior toe of the former perimeter dike of the PAP.
- West Trench
  - The west trench would be located in the vicinity of APW02 to address impacts of lithium, sulfate, and TDS at APW02.
  - The west trench would extend from grade surface to approximately 25 to 35 feet bgs to an approximate elevation of 510 feet in order to capture impacted groundwater in the UA and PMP.
  - The west trench would have a total length of approximately 2,500 feet, extending along the exterior toe of the former perimeter dike of the PAP.

The preliminary depth and extents of both trenches were based on available groundwater and other site data and may be adjusted during future phases of design. The trenches would be constructed by excavating existing subgrade soils, installation of a collection pipe in the trench, backfilling with clean granular fill, and placement of a compacted cap over the trench to reduce surface water infiltration. The collection pipes would drain to sump pumps spaced throughout each trench. Extracted groundwater would be collected and routed via pneumatic pumps and air compressors to a new on-site lined settling pond and discharged through either a new or existing outfall, where it would be managed in accordance with the National Pollutant Discharge Elimination System (NPDES) permit for the site.

A feasibility-level drawing of the source control with GWET remedy is provided as **Figure 2** in **Appendix A.**

3.1 Remedy Scoping and Groundwater Modeling Results

The locations of the GWETs were selected by reviewing physical constraints around the PAP and designating locations on IPGC property where the trenches could feasibly be constructed with limited impacts to other site features. The locations were additionally selected to address exceedances in the vicinity of APW02 on the western side of the PAP and APW10 on the eastern

[2] All elevations in this report are in the North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

side of the PAP, while avoiding sensitive areas such as wetlands and floodplains [9, 10, 11] and limiting other adverse impacts or conflicts with the PAP final closure construction, Newton Lake, and other site utilities or features. This resulted in both the east and west GWET being located along the exterior toe of the former perimeter dike of the PAP, adjacent to Newton Lake. The selected locations have accessible space which is not within regulatory floodplains or known wetlands to allow for trench construction. Additionally, the areas are outside the limits of the PAP final closure, and therefore would reduce impacts to the final closure construction.

The depths of the GWET were selected using iterative, three-dimensional groundwater fate and transport modeling. Various depth intervals were tested during groundwater modeling simulations to identify optimal depths to achieve reduction in the time to reach GWPS while also remaining feasible to construct and operate. During these groundwater modeling simulations, the addition of a downgradient cutoff wall, intended to reduce inflows from Newton Lake from reaching the trench, was determined not to be beneficial and did not result in additional reduction in the time to reach GWPS. Thus, the use of cutoff walls as a corrective technology, either combined with GWE or as a standalone remedial measure, was not further considered in this CAAA-SIR.

Groundwater modeling for the Alternative 2 remedy (**Appendix B1**) estimated that GWPS would be met in 33 years after the implementation of source control and the remedy for all wells within the existing PAP monitoring well system.

3.2 Remedy Implementation

Implementation of the Alternative 2 source control with GWET remedy is expected to include multiple tasks spread out over three phases, including pre-construction activities (Phase 1), corrective action construction (Phase 2), and corrective action operations, maintenance, and closeout (Phase 3). Information for each phase is described in this section.

3.2.1 Phase 1: Pre-Construction Activities

Pre-construction activities would include further pre-design investigation, obtaining permits from other agencies, completing the final design of the remedy, and selecting a remedy implementation contractor via a bidding process. Information associated with each of these activities is descried below.

- Completing pre-design investigation, final design and bid activities, including:
  - Completing additional subsurface investigations and groundwater monitoring data to further refine the necessary extents of both the east and west trenches.
  - Completion of final design subsurface investigations, laboratory soil testing, engineering calculations, design drawings, specifications, and a construction quality assurance plan.
  - Bidding and selection of the GWET system construction contractor.
- Obtaining permits from other agencies including:
  - A general stormwater permit for construction site activities though IEPA, including construction stormwater controls and other best management practices (BMPs) such as silt fences and other measures.

- Illinois Department of Natural Resources (IDNR) Office of Water Resources, Dam Safety modification permit, for modification of the embankment (if determined to be necessary).
- A modification to the site's NPDES outfall for the management and discharge of extracted groundwater.

3.2.2 Phase 2: Corrective Action Construction

Corrective action construction would be initiated after pre-construction activities are complete. It would include mobilizing construction equipment to the site, preparing the site for construction activities, construction of the GWETs (which would include replacement of existing subgrade soils with permeable trench materials), and performing post-construction and site restoration activities.

Extraction trench construction is assumed to occur concurrently within the latter phases of the PAP closure construction, utilizing a contractor separate from the closure construction contractor. This would allow spoils generated during extraction trench construction to be placed beneath the final cover system within the PAP. This would likely mean that the GWET would be constructed after the PAP has been dewatered and CCR has been removed from the closure-by-removal portions of the PAP, but before the final cover system has been completed. This would also reduce the risk of GWET construction potentially destabilizing or causing other distress of the PAP perimeter dike. This would act as a risk mitigation measure, as dike destabilization could lead to a release CCR-impacted water that would be present prior to dewatering of the PAP.

Information associated with each of these activities is described below.

- The contractor would mobilize equipment, construction facilities, and materials to the site, and install stormwater BMPs around the construction area, construct a staging and laydown area, perform tree and vegetation clearing along the trench alignment, and construct temporary access roads leading from the extraction trench alignment to the existing site access road.
- The existing fire water supply line extending from the pump house adjacent to Newton Lake to the NEW would be abandoned and rerouted to make way for construction of the eastern extraction trench.
- Materials and earthwork required to construct an approximately 40-foot wide engineered, earthen work pad would be completed along the GWET construction zones. Grading and surface improvements would also be made to allow for vehicle access along the work pad.
  - For the east trench, this would include excavating into the existing grades in some areas and filling in other areas to provide a level work pad.
  - The existing area around the western trench is relatively level and would require stabilizing the ground surface.
  - Construction of the earthen work pad would include removing, relocating, or modifying existing site infrastructure to allow the platform to be constructed.
  - Affected infrastructure includes, but is not limited to, the existing fire water supply line that extends from the pump house to the plant area, existing monitoring wells and piezometers, fencing or electric utilities, or other features that may conflict with the construction of the trenches.

- Geotechnical monitoring would be performed to ensure the integrity of the PAP perimeter dikes during construction of the GWETs.
- The GWETs are assumed to be constructed using one-pass trenching methods. This method involves the use of a specialized one-pass trencher that would excavate subgrade soils, place collection piping and sumps, and backfill the trench with granular fill in a single operation. Other construction methods could be utilized if later determined to be appropriate based on site-specific subsurface conditions and constructability considerations.
  - The trenches would be excavated along the design alignment on the outer side of the former containment dike. Excavation would be conducted to the design depth, which terminates below the PMP (*i.e.*, Upper Drift unit). Perforated groundwater collection pipe would be laid in the trench base at an approximate 0.5 to 2% grade to slope towards the sump. The constructed trench is expected to be on the order of 3-feet wide.
  - Sump locations would be installed along the trenches. Sumps would consist of a pit to hold extracted water, a discharge line, a pneumatic pump to pump water to the discharge line, and an air compressor. Vertical sumps would be located every 200 to 300 feet along the length of each collection trench.
  - The trench would be backfilled with imported clean granular material and capped with low-permeability clay and topsoil at the surface, or a more erosion-resistant material (*i.e.*, a turf-reinforced mat or gravel), if needed to prevent stormwater erosion and infiltration of the trench.
  - Excavated soils (*e.g.*, spoils) would be placed into off-road dump trucks and hauled to the PAP for use as contouring fill beneath the final cover system (*i.e.*, subgrade). The material would be moisture-conditioned by spreading it in thin lifts and compacting in accordance with the subgrade fill specifications for the PAP final closure.
- An approximately 1-acre, geomembrane lined settling pond for management of extracted groundwater would be constructed using conventional construction equipment.
  - The settling pond would be sited to limit adverse impacts or conflicts with the PAP final closure construction and future solar redevelopment. The precise location of the pond would be evaluated during later design phases.
  - The settling pond is assumed to be approximately 1-acre in size and 5-feet deep. Soils from the settling pond excavation and/or from the construction of the eastern earthen work pad would be used to create 10-foot wide berms around the perimeter of the settling pond to contain extracted groundwater. All excavated soils from the settling pond would be managed within the settling pond footprint.
  - The settling pond may be located in the existing footprint of the former secondary pond located south of the PAP and the existing dikes may be utilized, as feasible.
- Electrical power drops would be installed in the eastern and western trench areas and the settling pond area, in order to provide power for pumping activities.
- Equalization tanks and transfer pumps would be placed at the surface adjacent to each trench due to the extended distance required for conveyance of extracted groundwater to the settling pond.

- Underground trenches would be excavated to allow placement of HDPE piping to convey extracted groundwater from the GWET to the settling pond and from the settling pond to either an existing or a new NDPES outfall to Newton Lake. Trenches would be backfilled with imported granular material.
  - An additional transfer pump may be required for discharge of extracted groundwater to the settling pond.
- Site restoration would be completed following the installation of the GWET. This would include repairing site infrastructure that was relocated or damaged during construction and minor regrading and seeding of disturbed areas.
- Temporary BMPs would also be installed during the site restoration period, if required in accordance with site land disturbance permits. The BMPs would be removed once vegetation is established.

3.2.3 Phase 3: Corrective Action Operations, Maintenance, and Closeout

Corrective action operations, maintenance, and closure would be initiated after corrective action construction is completed. It would include performing corrective action groundwater monitoring, and, after GWPS have been met, performing corrective action closeout and completion activities. Information associated with each of these activities is described below.

- Corrective Action O&M
  - Continued operation of the GWET would require routine, scheduled inspections and associated maintenance including, but not limited to, totalizer data collection, and maintenance of extraction pumps as well as other system components.
  - Non-routine maintenance that may occur during extended operation of the GWET may include tasks such as repair or replacement of the extraction pumps, repair or replacement of a system air compressor, and flushing or jetting of water conveyance lines in the event organic or inorganic solids accumulate on the interior walls.
  - Routine monitoring and compliance activities associated with the treatment and discharge of extracted water via the site's NPDES permit and either existing or new outfall would also be completed during this phase.
  - Ongoing operation and associated O&M activities of the GWET would continue for approximately 33 years or until GWPS are met. Once GWPS were achieved, the extraction system would be shut off and O&M would cease.
- Corrective Action Groundwater Monitoring
  - Regular corrective action groundwater monitoring would be conducted using a corrective action groundwater monitoring network designed in accordance with 35 I.A.C. § 845.680(c), which specified that wells must be installed within the plume of contamination that lies beyond the waste boundary.
    - Samples will be collected for major ions for evaluating groundwater chemistry and COCs. Samples will be collected on a quarterly basis initially and potentially reduced to a semiannual basis once five years of monitoring have occurred, in accordance with 35 I.A.C. 845.650(b)(4).

    - Monitoring results would be submitted to IEPA after each monitoring event, in addition to an annual groundwater monitoring and corrective action report, in accordance with 35 I.A.C. 845.640(e). The annual corrective action report would include an evaluation of the actual performance of the remedy relative to the remedy's expected performance.
    - Routine maintenance of the monitoring well network would be conducted during the monitoring period. This would include inspection of the wells, making repairs to the wells (as and if needed), and rehabilitation and/or replacing the wells to improve performance (as and if needed).
  - If the remedy does not achieve its expected performance, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. 845.680(b).

- Adaptive Management during Monitoring
  - Groundwater monitoring results would be evaluated and documented in in the monitoring reports submitted to IEPA, in accordance with 35 I.A.C. 845.610(e)
  - Remedy progress evaluation as part of adaptive site management may include additional investigation to inform updates to the CSM, groundwater, and geochemical models.
  - If remedy progress does not correspond with expectations, additional methods or techniques to achieve compliance with GWPS would be evaluated and, if feasible, implemented in accordance with 35 I.A.C. 845.680(b).
- Corrective Action Confirmation Monitoring and Completion
  - After GWPS have been met for all compliance wells for a period of three years, corrective action would be considered complete, per 35 I.A.C. 845.680(c).
    - It should be noted that post-closure care groundwater monitoring required for a 30-year period by 35 I.A.C. 845.780(c) would continue to occur after corrective action groundwater monitoring is expected to be completed.
  - After completion of the corrective action confirmation monitoring period, a Corrective Action Completion Report and Certification would be prepared and submitted to IEPA, in accordance with 35 I.A.C. 845.680(e).

3.2.4 Remedy Implementation Schedule

A feasibility-level implementation schedule for the Alternative 2 source control with GWET is provided in **Table B** on the following page.

Table B. Feasibility-Level Implementation Schedule – Alternative 2 Source Control with GWET

Implementation Phase	Implementation Task	Timeframe (Preliminary Estimates)
1: Pre-Construction	Agency Coordination, Approvals, and Permitting	18 to 24 months
	Final Design and Bid Process	24 to 36 months
	Timeframe to Complete Corrective Action Pre-Construction Activities	42 to 60 months after Corrective Action Plan Approval
2: Corrective Action Construction	Corrective Action Construction	9 to 18 months
	Timeframe to Complete Corrective Action Construction	9 to 18 months
3: Corrective Action O&M and Closure*	Corrective Action Monitoring (Time to Meet GWPS)	396 months
	Corrective Action Confirmation Monitoring	36 months
	Corrective Action Completion	6 months
	Timeframe to Complete Corrective Action O&M and Closeout	438 months
	Total Timeline to Complete Corrective Action	489 to 516 months (41 to 43 years)
	Total Timeline to Complete Corrective Action (after completion of source control)	438 months (36.5 years)

*Denotes a timeframe that is assumed to start after source control (*e.g.,* final closure of the SI) is complete and a corrective action construction permit application has been issued by IEPA, whichever is later.

It should be noted that Phases 1 and 2 were assumed to occur concurrently with closure construction, to allow spoils to be disposed of beneath the PAP final cover system. Therefore, the start of Phase 3 (Corrective Action O&M and closeout) is assumed to begin at the completion of source control (final closure of the PAP). In the event that Phases 1 and 2 could not be completed concurrently with source control, due to a delay in receiving permits or construction-related conflicts, the total schedule would likely increase.

3.2.5 Management of Extracted Groundwater

Extracted groundwater were assumed to be managed and treated by the GWE system and a newly-constructed settling pond, which would be located on site. However, other means for managing and treated extracted groundwater may be evaluated during later design phases. The settling pond would need to be sited to not conflict with site infrastructure. A settling pond approximately 1-acre in size was assumed to be sufficient to allow sediments to settle from extracted groundwater prior to discharge. Groundwater collected from the GWET would be sent to the settling pond via the pneumatic extraction pumps and transfer piping. Treated water would discharge via an existing or new NPDES outfall to Newton Lake. All groundwater would be discharged in accordance with site-specific NPDES permit requirements.

3.2.6 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) Information

As requested by Gradient, the following information required by 35 I.A.C. § 845.670(e)(1)(H) and 35 I.A.C. § 845.670(e)(3) has been developed for the remedy. The information was developed based on preliminary-level information contained within the CMA for the NEW PAP and

then refined based on additional feasibility-level design activities performed as part of the development of this CAAA-SIR.

- Potential Need for Replacement of the Remedy – 35 I.A.C. § 845.670(e)(1)(H)
  - No replacement of the remedy is expected to be required during the design life of the remedy, although the remedy would require ongoing monitoring and maintenance to retain its effectiveness.
- Degree of Difficulty Associated with Constructing the Remedy – 35 I.A.C. § 845.670(e)(3)(A)
  - The remedy would require use of specialized contractors and equipment (*i.e.*, one-pass trenching contractor and equipment) for the installation of the trenches, in addition to general construction equipment (*i.e*., excavation and grading equipment).
  - Construction of the GWET would require modifications to the PAP dike in order to provide an earthen work pad for construction equipment. In addition to likely requiring a permit from the IDNR, the construction would require a detailed geotechnical design of the earthen work pad and geotechnical monitoring of the embankment for signs of distress during construction. In the event that distress is noted, construction may need to be temporarily paused to evaluate the sources of the distress and mitigate, if needed.
  - The performance of the GWETs will be dependent on the construction techniques. Continuous quality control monitoring will be required during construction as part of construction quality control and quality assurance activities.
  - The performance of the GWET would also be dependent on the actual hydraulic conductivity of the geologic units surrounding the trenches. This may require additional pre-design investigation activities to confirm existing hydrogeologic conditions of the proposed trench locations.
- Expected Operational Reliability of the Remedy - 35 I.A.C. § 845.670(e)(3)(B)
  - The GWET are expected to have high operational reliability if constructed in accordance with the design and specifications.
  - The extraction trench system is a mechanical system that would require routine maintenance in order to reliably operate, as outlined in the Corrective Action O&M, **Section 3.2.3**.
- Need to Coordinate with and Obtain Necessary Approvals and permits from Other Agencies - 35 I.A.C. § 845.670(e)(3)(C)
  - Agency permits would need to be obtained from IEPA for construction stormwater controls and BMPs, modifications to the site's NDPES permit, and potentially an IDNR Dam Safety modification permit. These permits typically take 18 to 24 months to obtain.
    - While these permits may also be obtained for the PAP final closure, the schedule for approval is uncertain for the final closure plan and the eventual CAP, therefore it is has been assumed that separate permit applications for closure and corrective action construction would be submitted.
- Availability of Necessary Equipment and Specialists - 35 I.A.C. § 845.670(e)(3)(D)

- Construction of the GWET would require a specialized contractor experienced with construction of similar types of trenches in similar geologic environments. Relatively few construction contractors with this experience, particularly using one-pass equipment, are available. The contractor would likely need specialized and often custom-built equipment.
- Specialists in one-pass trenching methods would also need to be utilized during the design and construction phase. The specialists would include design engineers, construction managers, and contractor staff experienced with trench construction and equipment operation.
- Geotechnical specialists would be needed to design the earthen work pad and monitor the PAP embankment for signs of distress during one-pass trench installation.
- These types of equipment and specialists have been utilized in the past for other similar types of extraction trench design and construction projects. However, there may be backlogs associated with the equipment and specialists, due to high existing demand for specialty ground improvement contractors and design specialists who are supporting similar types of projects in the electric utility, dam/levee, and other market sectors. These backlogs could add additional delay to the project schedule above current assumptions.
- Specialists would be needed to maintain the GWE system during the operational timeframe and are currently being utilized as part of GWE O&M. System components that require maintenance include totalizers, instrumentation, and the extraction and transfer pumps.
    - Additionally, specialists are occasionally needed for non-routine O&M which may include flushing or jetting of the conveyance lines, replacement of faulty system components, replacement of pumps or pump controllers, and replacement of faulty system instrumentation.
    - Specialists and replacement equipment are generally available within proximity (100 to 300 miles) of the site but some of the more complex equipment, including the transfer pumps and transfer pump controller, may have extended lead times for replacement or servicing.
    - Equipment and specialists for field data collection, groundwater sampling, analysis, and periodic corrective action groundwater monitoring and reporting would be required for the remedy. As described in **Section 2.2.3**, the equipment and specialists required to support these activities are currently performing routine groundwater monitoring in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring in this alternative.
        - The equipment and specialists required for site groundwater monitoring and analysis are currently performing this work in accordance with 35 I.A.C. § 845.220(c)(4). Therefore, no new equipment or specialists are required for groundwater monitoring for this alternative.

- Available Capacity and Location of Needed Treatment, Storage, and Disposal Services – 35 I.A.C. § 845.670(e)(3)(E)
    - Wastes generated during GWET construction would be limited to spoils; these would be disposed of onsite in the PAP, during closure construction, as compacted contouring fill beneath the final cover system. Completing the extraction trench construction at the same

time as the PAP closure would provide sufficient on-site capacity for the disposal of generated spoils.

- The extraction trench system would send extracted groundwater to a settling pond on-site to settle solids extracted during groundwater recovery via the pneumatic extraction pumps and transfer piping. This settling pond would be new construction that would need to be sited, designed, constructed, and maintained.
- The settling pond would need to be sited to not conflict with planned solar redevelopment, wetlands, floodplains, or other site infrastructure.

4. MATERIAL QUANTITY, LABOR, AND MILEAGE ESTIMATES

Estimates of material quantities, total labor hours, and mileage were prepared for Alternative 2 source control with GWET, to support Gradient in preparing a CAAA. Estimates were prepared for the construction and O&M of each remedy. Estimates were not prepared for Alternative 1 source control with GWP as the alternative does not require remedial construction or O&M of a physical remedy.

Estimates were prepared utilizing the following approach:

- Major implementation (*e.g.,* construction) components and line items were identified, in accordance with the remedy implementation narratives contained within this CAAA-SIR.
- Construction quantities were estimated based on quantity estimates for volumes, areas, and units, as obtained from the feasibility-level engineering drawings and schedules included within this CAAA-SIR.
- RS Means Heavy Construction Cost Data (RS Means) [12] was utilized to estimate the crew size, equipment description, and daily output associated with each line item.
- For line items where RS Means data was not available, the crew size, equipment description, and daily output were estimated based on Ramboll's experience, information from contractors, and/or information from material suppliers.
- For the Alternative 2 source control with GWET remedy, daily construction and O&M labor mobilization miles were estimated assuming a weekly mobilization/demobilization from Chicago (720 miles round trip) and a local commute of 40 miles round trip per day. The number of working days and hours per week were estimated from the construction schedule developed for each remedy.
- Estimates of material delivery miles were prepared based on Ramboll's experience.

The detailed material quantity, labor, and mileage estimates are provided in **Appendix C** for each alternative.

EXECUTIVE SUMMARY

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Groundwater Modeling Technical Memorandum ("Tech Memo") on behalf of the Newton Power Plant (NPP), operated by Illinois Power Generating Company (IPGC), in accordance with requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845. This document presents the results of additional predictive groundwater modeling simulations in support of the Corrective Action Alternatives Analysis (CAAA) required by 35 I.A.C. § 845,670(e), for the Primary Ash Pond (PAP) in Newton, Illinois, identified by Illinois Environmental Protection Agency (IEPA) identification (ID) number (No.) W0798070001-01 and National Inventory of Dams (NID) No. IL50719.

This document presents the evaluation of two potential corrective action remedial alternatives aimed at achieving compliance with applicable groundwater standards. The primary objective of the groundwater modeling effort was to assess the long-term effectiveness and the timeframe required to achieve Groundwater Protection Standards (GWPS)[1] for two scenarios:

- Alternative 1. source control with groundwater extraction trenches, and
- Alternative 2. source control with groundwater extraction trenches augmented by a cutoff wall.

Both alternatives assume that the source control presented in the Final Closure Plan Version 1 (HDR, 2025) for the PAP would also be implemented. Source control is the primary corrective action for the PAP and would include removing free liquids from the CCR and completing a hybrid closure-in-place (CIP) by consolidating the current PAP footprint from 404 acres down to 252 acres (the CIP area) and installing a geomembrane final cover system. The predictive groundwater model simulations were divided into three distinct periods: current conditions, dewatering and closure construction, and post-closure.

Under the baseline closure-in-place (CIP) scenario (Ramboll 2025b), the predicted concentration of sulfate in monitoring wells attained the GWPS within 34 years. The Corrective Action Plan (CAP) simulations were extended from the baseline CIP model (Ramboll, 2025b), to evaluate the performance of Alternatives 1 and 2 described above. Modeling involved the use of MODFLOW and MT3DMS for simulating groundwater flow and contaminant transport.

This memorandum examines two remedial alternatives: (1) Source control with groundwater extraction trenches, and (2) Source control with groundwater extraction trenches and a cutoff wall intended to reduce flow volumes into the eastside trench from the adjacent Newton Lake. The first alternative includes constructing two downgradient groundwater extraction trenches near APW10 and APW02, located between the PAP and Newton Lake. The second alternative involves adding a cutoff wall adjacent to the eastside trench.

The predictive model includes these new components. The optimal depths for the extraction trenches were determined through a series of iteration of three-dimensional groundwater fate and transport models. Various depth intervals were examined in these simulations to find the optimal balance between reducing the time needed to attain the GWPSs and maintaining the practicality of construction and operation. Factors taken into account during modeling included

[1] Sulfate was selected for modeling source control presented in the Final Closure Plan and was identified as a surrogate for the exceedances of lithium and TDS, as described in the GMR (Ramboll, 2022).

how the height of the trench's water elevation (stage) compared to that of Newton Lake, as well as the effects of different penetration depths of cutoff wall.

Predictive modeling of Alternative 2, indicated that the addition of a cutoff wall did not enhance the effectiveness of the extraction trenches in reducing the time to reach GWPS and also did not significantly reduce volumes of extracted groundwater.

1. INTRODUCTION

1.1 Background

This Tech Memo is prepared to evaluate how two potential corrective action remedial alternatives would achieve compliance with the applicable groundwater standards in support of the CAAA. The groundwater modeling efforts consist of predictive fate and transport modeling to assess the long-term effectiveness and time for achieving GWPS for sulfate for the following groundwater remedial alternatives: (1) source control with groundwater extraction trenches, and (2) source control with groundwater extraction trenches augmented with a cutoff wall. In both cases, source control is the CIP scenario that was selected as the closure alternative for the PAP (HDR, 2025).

1.2 Previous Groundwater Modeling Reports

In accordance with requirements of 35 I.A.C. § 845, Ramboll developed the Newton MODFLOW and MT3DMS Groundwater flow and transport models (original model) in 2022 and submitted the report (Ramboll, 2022) as an attachment to the Construction Permit Application for NPP PAP in June 2022. The groundwater model was revised in 2025 (Ramboll, 2025b) and the results were included in an attachment to the revised Construction Permit Application (HDR, 2025).

The COCs currently exceeding[2] the GWPS at compliance groundwater monitoring wells that are attributable to the PAP as of the 2024 Annual Report (Ramboll, 2025a) include lithium, sulfate, and TDS. A surrogate parameter was selected for groundwater flow and transport modeling that is a conservative parameter (i.e., aqueous concentrations are predominantly affected by physical processes such as dilution and dispersion rather than by chemical attenuation mechanisms) and therefore represents the maximum plume extent. The use of a conservative parameter to represent plume extent and clean-up times is consistent with USEPA modeling examples intended for evaluating relative remedy effectiveness[3]. For modeling purposes, sulfate was identified as the surrogate, and it was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]) which is a conservative estimate for predicting contaminant transport times in the model. Sulfate transport is likely to be affected by both chemical and physical attenuation mechanisms (i.e., adsorption and/or precipitation reactions as well as dilution and dispersion). Physical attenuation (dilution and dispersion) of contaminants in groundwater is simulated in the groundwater computer models. Chemical attenuation mechanisms and their effect on modeled times for exceedances to reach the GWPS are discussed in the Groundwater Polishing Evaluation Report (Ramboll, 2025c) and summarized in **Section 3.2.**

Prior modeling results indicated that groundwater flow downward through the upper drift (UD) and upper confining unit (UCU) into the uppermost aquifer (UA) which is consistent with the Hydrogeologic Site Characterization Report (Ramboll, 2021). Groundwater in the UA flows from north to south/southwest and converges near a former drainage feature located west of the PAP. (Ramboll, 2022). The 2022 MODFLOW and MT3DMS models were used to evaluate two closure scenarios, including CCR consolidation and CIP, and closure-by-removal (CBR). The CIP was

[2] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or Groundwater Protection Standards (GWPSs) as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 31, 2021 as part of IPGC's operating permit application for the PAP. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, IPGC has not identified any actual exceedances.

[3] USEPA. 1994. Ground-Water Modeling Compendium. Second Edition. Office of Solid Waste and Emergency Response. 500-B-94-004. July.

selected as the preferred alternative to meet regulatory requirements for closure of the PAP. The groundwater remedial alternatives evaluated in this memo are an extension of the model simulations developed for the CIP scenario (source control CIP scenario) in 2025 (Ramboll, 2025b).

2. BASELINE SIMULATION OF CLOSURE-IN-PLACE (CIP)

The revised GMR (Ramboll, 2025b) simulates closure of the PAP as described in the *Primary Ash Pond Final Closure Plan* (HDR, 2025). The PAP will be closed using a consolidate-and-cap approach consisting of excavating nearly 3.6 million cubic yards of CCR and placing it in a consolidated CCR footprint at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table (HDR, 2025). The results of the revised groundwater modeling are summarized below. No changes were made to the 2025 revised GMR model prior to simulation of remedial alternatives.

2.1 Model Description

CIP was simulated using the calibrated historical flow and transport model for the PAP as a base, to be consistent with the specifications and timelines expressed in the *Primary Ash Pond Final Closure Plan Version 1* (HDR, 2025).The model was developed to simulate three explicit periods of closure: current conditions (Period 1), dewatering and closure construction (Period 2), and post-closure (Period 3) (Ramboll, 2025b).

2.2 Simulation Results

Figure 1 presents the location of monitoring wells with exceedances of the sulfate GWPS and proposed extraction trenches at the west and east side of PAP. **Figure 2(A)** presents concentrations of sulfate following closure at five (APW02, APW04, APW05S, APW10, and APW12) of the 26 PAP monitoring wells which have average or maximum concentrations observed between 2015 and 2021 exceeding the GWPS of 400 milligrams per liter (mg/L) (**Table 1**). In the baseline CIP scenario, predicted concentration of sulfate attained the GWPS at these locations within approximately 1 to 34 years of completion of the CIP remedy, with a mean time of 12 years (**Figure 2(A) and Table 1**). Sulfate concentrations in AWP04 were predicted to attain 400 mg/L within 34 years which is the longest time to reach below GWPS (**Table 1** and **Figure 2(A)**).

3. CORRECTIVE ACTION PLAN ALTERNATIVE SIMULATIONS

The CAP remedial alternatives (groundwater extraction trench and cutoff wall) were simulated to evaluate effects of additional remedial actions, beyond CIP, on sulfate concentrations at the PAP. The CIP simulations provided in the revised GMR (Ramboll, 2025b) provide a baseline source control scenario for comparison to additional remedial action.

The groundwater modeling activities documented in this report utilized the following software and model codes, consistent with previous modeling:

- Groundwater flow was simulated in three dimensions using the original MODFLOW version 88/96.
- The Horizontal Flow Barrier (HFB) package of MODFLOW was used to simulate the cutoff wall scenario.
- Contaminant transport was simulated in three dimensions using MT3DMS.
- Use of Groundwater Vistas as a MODFLOW/MT3DMS processing tool

3.1 Alternative 1. CIP with Groundwater Extraction Trenches

3.1.1 Overview

This remedy alternative, source control with groundwater extraction, would include the construction of two downgradient groundwater extraction trenches. **Figure 1** presents the location of monitoring wells with exceedances and proposed extraction trenches at the west and east side of PAP. The trenches would be located in the vicinity of APW10 (east side of PAP) and APW02 (west side of PAP) and will be located between the PAP and the adjacent Newton Lake in both areas. The goal of this alternative is to capture impacted groundwater from the UA and PMP to reduce the time to reach GWPS while limiting inflow from the lake. The trench at APW10 will extend from grade surface to approximately 30 feet below ground surface (bgs) to an approximate elevation of 503 feet[4]. The total length of the APW10 groundwater extraction trench will be approximately 1,400 feet, extending along the exterior toe of the former perimeter dike of the PAP. The trench at APW2 will extend from ground surface to approximately 25 to 35 feet bgs to an approximate elevation of 510 feet. The total length of the APW02 groundwater extraction trench will be approximately 2,500 feet, extending along the exterior toe of the former perimeter dike of the PAP.

3.1.2 Model Approach

To simulate Alternative 1 the CIP predictive model, as presented in the revised GMR, was modified to include a groundwater extraction trench situated along the berm near APW10 (east side of PAP) and APW02 (west side of PAP). These wells are located between PAP and the adjacent Newton Lake in both areas, aiming to capture groundwater from PAP. The depths of the extraction trenches were selected using iterative, three-dimensional groundwater fate and transport modeling. Various depth intervals were tested during groundwater modeling simulations to identify optimal depths to achieve reduction in the time to reach GWPSs while also

[4] All elevations in this report are in the North American Vertical Datum of 1988 (NAVD88), unless otherwise noted.

remaining feasible to construct and operate. Modeling considerations included the trench stage relative to Newton Lake's stage. **Table 2** presents a summary of the model construction details for the extraction trenches for each scenario.

Extraction trenches are represented in the model using the Drain package of MODFLOW, with conductance values set to 10,000 square feet per day (ft^2/day) that corresponds to concrete sand hydraulic conductivity (2.2 x 10^{-2} cm/sec or 62.4 ft/day), to facilitate adequate water flow. The drain stage is assumed to be 1 foot above the bottom of the drain cell, providing sufficient space for the placement of a perforated extraction pipe. In Alternative 1, an extraction trench was implemented in the eastern side, with the drain stage set at an elevation of 503 ft, which is lower than the lake's head elevation of 504.62 ft due to the presence of exceedances in the UA well APW10. The extraction trench on the west side uses a drain stage of 510 ft, which is greater than the lake elevation because exceedances are limited to the shallow PMP wells APW02.

3.1.3 Alternative 1 Simulation Results

Figure 2(B) presents concentrations of sulfate simulated for Alternative 1 following closure at the same five wells with sulfate exceedances (**Table 1**). In the Alternative 1 scenario, predicted concentration of sulfate attained the GWPS within approximately 1 to 33 years of completion of the CIP remedy, with a mean time of 9 years (**Figure 2(B) and Table 1**). Sulfate concentrations in AWP04 were predicted to attain 400 mg/L within 33 years which is the longest time to attain the GWPS for this alternative.

The approximate extraction rates from the trenches are initially 10.7 and 0.2 gpm for the eastside and westside trenches, respectively. Extraction rates are predicted to decrease with time such that at the time the GWPS is attained extraction rates have declined to approximately 1.2 and 0.1 gallons per minute (gpm) for eastside and westside trenches respectively (**Figure 3**).

3.2 Alternative 2. CIP with Groundwater Extraction Trenches and Cutoff Wall

3.2.1 Overview

This remedy alternative, source control with groundwater extraction and cutoff wall, is based on Alternative 1 with the addition of a cutoff wall adjacent to the east side trench to determine if the additional cutoff wall will improve time to reach the GWPS and/or decrease the volume of extracted water from the eastern trench which is in close proximity to Newton Lake.

3.2.2 Model Approach

The cutoff wall was represented in the model using the HFB package of MODFLOW, for the purpose of reducing groundwater inflows from Newton Lake into the trench. The wall thickness is set at 3 feet, and its hydraulic conductivity at 1 x 10^{-7} centimeters per second (cm/s) or 0.000283 feet per day (ft/d), assuming a cement-bentonite or soil-bentonite backfill composition. The cutoff wall extends from the ground surface to the bottom of model layer 6 which is lower than the base of the drain which is in layer 5. Layer 6 is underlain by the UA and Lower Confining Unit (LCU), consisting of sand, gravel, silty clay (layer 6), and lean clays of Smithboro (layer 7) with horizontal hydraulic conductivities ranging from 1 x 10^{-3} ft/d. In general, the lower cutoff wall elevation is between 473 to 476 feet. The cutoff wall was introduced solely in the eastside, focusing on the area where APW10 has observed exceedance in the UA. The east side extraction

trench, adjacent to APW10, intersects each of the four model layers (namely, layers 1 through 4) with the drain cells' stage set at elevation of 503 feet (**Table 2**).

3.2.3 Alternative 2 Simulation Results

Figure 2(C) presents concentrations of sulfate simulated for Alternative 2 following closure at the same five wells with sulfate exceedances (**Table 1**). In the Alternative 2 scenario, predicted concentration of sulfate attained the GWPS within approximately 1 to 33 years of completion of the CIP remedy, with a mean time of 9 years (**Figure 2(C) and Table 1**). Sulfate concentrations in AWP04 were predicted to attain 400 mg/L within 33 years which is the longest time to attain the GWPS for this alternative.

The extraction rates for Alternative 2 did not change significantly from Alternative 1. The approximate extraction rates from the trenches are initially 10.7 and 0.2 gpm for the eastside and westside trenches, respectively. Extraction rates are predicted to decrease with time such that at the time the GWPS is attained extraction rates have declined to approximately 1.2 and 0.1 gallons per minute (gpm) for eastside and westside trenches respectively (**Figure 3**).

3.3 Assessment of Geochemical Processes

This groundwater flow and transport model estimates the time for sulfate to reach the GWPS under different potential corrective actions based on physical components of groundwater polishing. As described in the Groundwater Modeling Report submitted with the construction permit, it was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (distribution coefficient [Kd] was set to 0 milliliters per gram [mL/g]), which is a conservative estimate for estimating contaminant transport times.

A Groundwater Polishing Evaluation Report (GPR) was prepared as an attachment to the Corrective Actions Alternative Analysis (CAAA) prepared by Gradient for Newton Power Plant Primary Ash Pond (NPP PAP). The geochemical modeling effort presented in the GPR supports the assessment of groundwater polishing as a component of the proposed corrective action by evaluating the potential for chemical attenuation of constituents of concern COCs before and after source control as a means of contextualizing the times estimated in the flow and transport model. The GPR also provides an initial foundation for understanding groundwater chemistry to inform adaptive site management as a key component of the Corrective Action Groundwater Monitoring Program.

Results from the speciation modeling presented in the GPR show that a substantial proportion of lithium and minimal amount of sulfate are retained in the solid phase under current conditions. Solid sorbing phases are anticipated to be stable as current geochemical conditions return to background conditions following source control. Desorption of lithium may result in transient increases in concentration after source control is completed. Desorption from sulfate from the solid phase is unlikely to effect on dissolved phase concentrations after source control is completed.

Results provided in the GPR confirm that sulfate does not significantly sorb or chemically react with aquifer solids; therefore, geochemical changes are not expected to have an effect on the modeled time to reach the GWPS for sulfate. GPR modeling results interpreted in conjunction with site-specific observations indicate that mobilization of currently sorbed lithium may contribute to dissolved phase concentrations of lithium in groundwater after source control, but

the magnitude of that desorption may be substantially lower than indicated by the model results. Adaptive site management, a critical aspect of every corrective action considered in the CAAA, will be used to monitor performance of the corrective action plan.

The GPR modeling evaluates return to background conditions following source control which will be completed for all of the remedial alternatives simulated in the groundwater modeling technical memorandum; as such, any transient mobilization of lithium that may occur as modeled in the GPR has the same potential to occur regardless of the remedial alternative selected. In other words, because all the remedial alternatives evaluated include the same source control measure of consolidation with a protective cover system, the potential for mobilization of lithium modeled in the GPR will be the same for all remedial alternatives evaluated.

The results of geochemical modeling do not suggest any modifications or adjustments are necessary to the groundwater model estimates of time to reach the GWPS for the following reasons:

- Sulfate which was modeled as a surrogate for all potential GWPS exceedance parameters does not significantly sorb or chemically react with aquifer solids; therefore, geochemical changes are not expected to have an effect on modeled time to reach the GWPS.
- Potential mobilization of lithium modeled in the GPR will be the same for all remedial alternatives evaluated; therefore, the groundwater model can be used to compare and contrast all of the remedial alternatives.

4. CONCLUSIONS

The groundwater modeling efforts in this tech memo consist of flow and transport modeling using MODFLOW and MT3DMS to assess the time to achieve GWPS for sulfate for two different remedy alternatives: (1) source control with groundwater extraction trenches, and (2) source control with groundwater extraction trenches augmented by a cutoff wall. The effects of these two corrective measures were evaluated along with the CIP scenario that was selected as the closure alternative for the PAP in 2022 and revised as documented in April 2025 (HDR, 2025).

The results of groundwater flow and transport modeling indicate that there is no significant difference in the time to attain the GWPS in compliance monitoring wells between the three scenarios (**Table 1**). Alternatives 1 and 2 attained the GWPS one year earlier than the CIP scenario. Timeframes to attain GWPS in the groundwater monitoring wells summarized in **Table A** below indicate that 60% of progress is expected to occur within the first five years for all scenarios. Alternatives 1 and 2 show more improvement at 10 years due to the reduced time to attain the GWPS at UD well APW02 compared to CIP. APW04 is the last well predicted to attain the GWPS approximately 30 years after source control is complete.

Table A. Estimated Timeframes to Attain GWPS in Groundwater Monitoring Wells

Scenario	Percentage of Wells Predicted to Attain the GWPS				
	1 year**	5 years**	10 years**	33 years**	34 years**
Baseline (CIP)	40 %	60 %	60 %	80 %	100 %
Alternative 1	40 %	60 %	80 %	100 %	100 %
Alternative 2	40 %	60 %	80 %	100 %	100 %

*: 5 wells were used to estimate time to reach GWPS
**: Years counted starting from completion of source control.

The approximate extraction rates from the trenches in Alternative 1 are initially 10.7 and 0.2 gpm for the eastside and westside trenches, respectively. Extraction rates are predicted to decrease with time such that at the time the GWPS is attained extraction rates have declined to approximately 1.2 and 0.1 gallons per minute (gpm) for eastside and westside trenches, respectively. Placement of the cutoff wall adjacent to the eastside trench resulted in no significant reduction in the estimated extraction rates. The extraction rates for Alternative 2 did not change significantly from Alternative 1 both start at approximately 10.7 gpm and decrease to 1.2 gpm at the time GWPS is attained for eastside trench and 0.2 to 0.1 for westside trench. The construction of a low-permeability cutoff wall did not have a significant impact on the performance of the extraction trenches in terms of reducing the time to reach GWPS as indicated by the unchanged times between scenarios. Therefore, this approach was not further evaluated.

EXECUTIVE SUMMARY

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has prepared this Groundwater Modeling Report (GMR) on behalf of the Newton Power Plant (NPP), operated by Illinois Power Generating Company (IPGC), in accordance with requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845: Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments (I.A.C., 2021). This document presents the results of predictive groundwater modeling simulations for proposed closure scenarios for the Primary Ash Pond (PAP), Vistra identification (ID) number (No.) 501, IEPA ID No. W0798070001-01, and National Inventory of Dams No. IL50719.

Revision 1 of this groundwater modeling report was prepared to document groundwater flow and transport simulations of the most current closure-in-place scenario presented in the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, Inc. [HDR], 2025 TBD). The current closure-in-place scenario differs from the previously proposed scenario by removing coal combustion residuals (CCR) from the former drainage channel present in the center of the CCR unit, and consolidating CCR to the east and west sides of the former drainage. The PAP will be closed using a consolidate-and-cap approach consisting of excavating nearly 3.6 million cubic yards of CCR and placing it in a consolidated CCR footprint at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table.

The NPP is located in Jasper County in the southeastern part of central Illinois, approximately seven miles southwest of the town of Newton (**Figure 1-1**). The PAP is located south of the NPP and situated in a predominantly agricultural area. The PAP is surrounded by Newton Lake on the west, south, and east. Beyond the lake is additional agricultural land.

A detailed summary of NPP conditions was provided in the Hydrogeologic Site Characterization Report ([HCR] Ramboll, 2021a). This report integrates existing NPP data and information with the latest hydrogeology and groundwater quality data to generate a conceptual and numerical model of the PAP. The conceptual site model (CSM) includes hydrogeologic and groundwater quality data specific to the PAP, which has been collected between 2015 and 2021. The PAP is a 9,715 acre-feet earthen berm CCR surface impoundment located south of the power plant. In addition to the CCR within the PAP, there are six layers of unlithified material present above the Pennsylvanian-Age bedrock. These materials have been categorized into five hydrostratigraphic units presented below in descending order:

- **Upper Drift (UD)/Potential Migration Pathway (PMP):** The UD is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.,* PMP).
  - **Hagarstown Member/PMP**: The Hagarstown Member consists of the discontinuous, sandier deposits of the UD where present and overlies the Vandalia Till Member of the Glasford Formation (Vandalia Till).
- **Upper Confining Unit (UCU):** The UCU consists of a thick package of low permeability clays and silts of the Vandalia Till. This unit is a laterally continuous layer between the base of the CCR unit and the top of the UA.
- **Uppermost Aquifer (UA)**: The UA is composed of the Mulberry Grove Member, which has been classified as poorly graded sand, silty sand, clayey sand, and gravel.

- **Lower Confining Unit (LCU)**: The LCU is comprised of low permeability silt and clay of the Smithboro Till Member and the Banner Formation.
- **Bedrock Confining Unit (BCU):** The low permeability bedrock underlying the PAP is the Pennsylvanian-Age Mattoon Formation, which consists of a complex sequence of thin limestones, coals, black fissile shales, underclay, thick gray shales, and several well-developed sandstones. The Mattoon Formation has a maximum thickness of more than 600 feet in the central part of the Illinois Basin in Jasper County.

The Cahokia Formation, described in the regional geology of the HCR, occurs in modern river valleys and floodplains. These deposits (which may contain sand, silt, or clay with wood and shell fragments) are expected to occur along the southeastern boundary of the PAP associated with the east branch of Newton Lake and may be difficult to distinguish from the deposits of the UD and the top of the UCU given the observed heterogeneity in the Cahokia, UD, and UCU.

Groundwater migrates downward through the UD and UCU into the UA. Groundwater in the UA flows from north to south/southwest and converges near a former drainage feature located west of the PAP. Groundwater elevations vary seasonally, although generally less than one foot per year. The surface water elevation at Newton Lake (at location SG02) measured between February 15 and March 9, 2021 ranged from 504.42 to 504.84 feet North American Vertical Datum of 1988 (NAVD88). Groundwater elevations in the UA at downgradient wells were observed around 491 feet NAVD88 (approximately 15 feet lower than the lake elevation). The separation between measured groundwater elevations and lake elevations (and observed downward vertical gradients in wells) indicates groundwater does not flow into Newton Lake from the UA. As indicated by the observed heads and groundwater flow directions in the UA, surface water from Newton Lake is entering the UA. The UA also approaches the former land surface east of the PAP, now beneath Newton Lake, as illustrated in geologic cross section B'-B" (Figure 2-7 of the HCR). The CSM for modeling the PAP is as follows:

- Most hydrostratigraphic layers are laterally continuous across the area. The flat to gently rolling uplands are dissected by deeply incised streams (into the materials of the UD, UCU, and UA) that are tributaries to river systems in the area. Cahokia formation deposits are also located within the incised streams. Newton Lake was created by damming one of these tributary streams for use by the NPP. Increased water levels within Newton Lake induced flow of surface water into the UA through discrete and limited areas north and east of the PAP, creating the potentiometric surface observed beneath the PAP.
- The UA is separated from the bottom of the PAP by a minimum of 14 feet of low-permeability glacial till that comprises the UCU. This laterally continuous confining unit is a barrier to vertical migration of groundwater from the PAP to the UA. Erosion caused by incised streams and deposition of Cahokia formation deposits has occurred along the southeast corner of the PAP.
- Groundwater in the UA flows from north to south/southwest and converges near a former drainage feature located west of the PAP.
- Surface recharge and groundwater migrate vertically through the low permeability sediments of the UD and Cahokia deposits. Groundwater migrates horizontally through the higher permeability sediments of the PMP and the UA.
- The UA is heterogenous, with materials ranging from clayey sand to coarse gravels. The highly transmissive sands and gravel are prominent in close proximity to the PAP.

- The separation between measured groundwater elevations and lake elevations (and observed downward vertical gradients) indicates groundwater does not flow into Newton Lake from the UA. The connection between the UA and Newton Lake is spatially discrete and limited to areas northeast of the PAP.
- The PAP is constructed such that the earthen berm and base are in contact with the UCU.
- The stage within the PAP is managed with minimal (less than 3 feet) variability throughout the year.

Groundwater quality parameters were monitored in the shallow sands of the PMP and UA monitoring wells at the PAP as part of the groundwater quality investigations performed between 2015 and 2021. A review and summary of data collected from 2015 through 2021 for parameters with groundwater protection standards (GWPS) listed in 35 I.A.C. § 845.600 is provided in the HCR (Ramboll, 2021a). Groundwater concentrations presented in Table 4-1 of the HCR and summarized in the History of Potential Exceedances (Ramboll, 2021b) are considered potential exceedances because the methodology used to determine them is proposed in the Groundwater Monitoring Plan (GMP) (Ramboll, 2021c) and is pending approval by IEPA[1]. The parameters currently exceeding the GWPS at compliance groundwater monitoring wells that are attributable to the PAP as of the 2024 Annual Report (Ramboll, 2025a) include lithium, sulfate, and total dissolved solids (TDS).

Multiple lines of evidence that limited potential GWPS exceedances of pH in the PMP are not related to the PAP are provided in the technical memorandum (**Appendix A**), *Evaluation of Potential GWPS Exceedances* (Golder Associates USA Inc. [Golder], 2022a). Statistically significant correlations between sulfate concentrations and concentrations of lithium and TDS indicate sulfate is an acceptable surrogate for lithium and TDS in the groundwater model. Concentrations of these parameters are expected to change along with model predicted sulfate concentrations.

It was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (distribution coefficient [Kd] was set to 0 milliliters per gram [mL/g]), which is a conservative estimate for estimating contaminant transport times in the model. Lithium, sulfate, and TDS transport is likely to be affected by both chemical and physical attenuation mechanisms (*i.e.,* adsorption and/or precipitation reactions as well as dilution and dispersion).

All available hydrological information were used to construct a CSM and numerical model of the PAP. A steady state, 7-layer numerical model was constructed to characterize the long-term groundwater flow conditions at NPP. The hydrostratigraphic units included in the model were the UD, PMP, UCU, UA, and LCU. The BCU was not included in the model. Calibration of the model focused on simulating mean groundwater elevations for 30 wells at NPP by modifying hydraulic parameters for the different hydrostratigraphic units, alongside river and general head boundary conductance. The calibrated model represents a reasonable match to the observed head and sulfate concentration data.

[1] Throughout this document, "exceedance" or "exceedances" is intended to refer only to potential exceedances of proposed applicable background statistics or Groundwater Protection Standards (GWPSs) as described in the proposed groundwater monitoring program, which was submitted to the IEPA on October 31, 2021 as part of IPGC's operating permit application for the PAP. That operating permit application, including the proposed groundwater monitoring program, remains under review by the IEPA and, therefore, IPGC has not identified any actual exceedances.

The calibrated model was used to predict the sulfate concentration for two closure scenarios described in the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, 2025), including:

- **Scenario 1:** closure-in-place (CIP) including excavating nearly 3.6 million cubic yards of CCR and placing it in consolidated CCR footprints at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table, and construction of a cover system over the remaining CCR, and;
- **Scenario 2:** closure-by-removal (CBR) including removal of all CCR and regrading of the removal area.
- Prior to the simulation of these scenarios, a dewatering simulation was included which simulated the removal of liquid from the PAP prior to the implementation of the two scenarios.

Scenario 1 (CIP) is predicted to reduce total flux in and out of the Fill Unit (CCR) by greater than 99%, when simulated post-construction heads in the groundwater monitoring wells are predicted to stabilize. Reduction of post-closure flux of water has improved from 94% in the original closure plan to greater than 99% in the revised plan.

Predictive simulations of pond closure indicate simulated groundwater concentrations in the monitoring wells within the two transport zones, namely the UD/PMP and UA, will achieve the GWPS in 34 years and 14 years for the CIP and CBR closure scenarios, respectively. The model-predicted twenty-year time difference when GWPSs are achieved for CIP (34 years post-closure) and CBR (14 years post-closure) is not significant because the estimated duration of construction activities indicates that CBR will take longer to implement than CIP. Specifically, the timeline for CIP would be 3.2-4.3 years compared to 7.8-9.2 years for Closure-by-Removal with On-Site CCR Disposal (CBR-Onsite) and 22 years for Closure-by-Removal with Off-Site CCR Disposal (CBR-Offsite) as described in Section 2.1 of the Closure Alternative Analysis (Gradient, 2022) and confirmed in the Updated Closure Alternatives Analysis (Gradient, 2025).

The prediction simulations indicate that although the groundwater wells reach the GWPS, sulfate remains within the model beyond 100 years in both CIP and CBR scenarios. This is due to the sulfate mass retained within the thick UCU which underlies the PAP. The low vertical hydraulic conductivity of this thick unit leads to low flow rates through the unit which will require time to release the sulfate mass. However, in both the CIP and CBR scenarios, the plume footprint continues to recede with time and remains within the property boundaries, indicating these closure options are equally protective.

Results of groundwater flow and transport modeling conservatively estimate that groundwater concentrations will attain the GWPS for all constituents within 34 years of closure implementation for either CIP and CBR. Within the property boundary, residual sulfate will be present within the clay confining unit above the GWPS due to the slow release of sulfate from the UCU.

1. INTRODUCTION

1.1 Overview

In accordance with the requirements of 35 I.A.C. § 845 (IEPA, 2021), Ramboll has prepared this GMR on behalf of the NPP, operated by IPGC. This report applies specifically to the CCR unit referred to as the PAP. However, information gathered to evaluate other CCR units in the vicinity regarding geology, hydrogeology, and groundwater quality is included, where appropriate. This GMR presents and evaluates the results of predictive groundwater modeling simulations for two proposed closure scenarios: 1) CIP and 2) CBR.

1.2 Previous Groundwater Reports

Numerous hydrogeologic investigations have been performed at the NPP. The information presented in this GMR includes data collected as part of a 2021 field investigation and previous investigations summarized and presented in the HCR (Ramboll, 2021a) which was provided as an attachment to the initial operating permit application required by 35 I.A.C. § 845.230.

1.3 Site Location and Background

The NPP is located in Jasper County, Illinois approximately 7.5 miles southwest of the town of Newton. The PAP is located in Section 26 and the western half of Section 25, Township 6 North, Range 8 East (**Figure 1-1**). The PAP is located south of the power plant and situated in a predominantly agricultural area. The PAP is surrounded by Newton Lake on the west, south, and east. Beyond the lake is additional agricultural land. The region is characterized by relatively flat to gently rolling topography.

1.4 Site History and CCR Units

Three CCR units are present on the NPP property, including the PAP and two landfills: the Phase 1 Landfill (LF1) is located northwest and west of the PAP, and the Phase 2 Landfill (LF2) is located west of the PAP (**Figure 1-2**). The PAP was constructed in 1977 and has a design capacity of approximately 9,715 acre-feet. There is also a non-CCR 83.6 acre-feet Secondary Pond located immediately south of the PAP. The PAP has a surface area of 404 acres and the Secondary Pond has an area of 9.3 acres. The PAP currently receives stormwater runoff, bottom ash, fly ash, and low-volume wastewater from the plant's two coal-fired boilers. The PAP is operated per National Pollutant Discharge Elimination System Permit No. IL0049191, Outfall 001 (located at the Secondary Pond).

Prior to PAP construction, an incised stream gully existed at the site of the PAP. Areas within the impoundment were excavated during construction for native materials used to build the containment berms (AECOM, 2016).

2. SITE GEOLOGY AND HYDROGEOLOGY

The geology and hydrogeology of the PAP is described in detail in the HCR (Ramboll, 2021a). A short summary is provided below.

2.1 Stratigraphy

The unlithified stratigraphy within and immediately surrounding the PAP consists of the following in descending order: fill material and CCR; silt and clayey silt loess (Peoria Loess); weathered till of the Sangamon Soil; discontinuous gravel and sand (Hagarstown Member), sandy/silty till with discontinuous lenses of sand and gravel (Vandalia Till); sands of the UA (Mulberry Grove Member); and clay till (Smithboro Till and Banner Formation) (Rapps Engineering and Applied Science [Rapps], 1997). The Cahokia Formation, described in the regional geology of the HCR, occurs in modern river valleys and floodplains. These deposits (which may contain sand, silt, or clay with wood and shell fragments) are expected to occur along the southeastern boundary of the PAP associated with the east branch of Newton Lake and may be difficult to distinguish from the deposits of the UD and the top of the UCU given the observed heterogeneity in the Cahokia, UD, and UCU. Unlithified units overlay Pennsylvanian-age shaley bedrock (Mattoon Formation).

CCR is present within most of the PAP at thicknesses between 17 to 19.5 feet thick as observed in porewater wells XPW01 through XPW04. The lowest bottom of ash elevation observed is approximately 486 feet in the center of a former drainage feature oriented north-south through the center of the PAP, whereas ash is potentially highest in elevation at approximately 550 feet along the outer edges of the PAP. The bottom of ash surface appears to mirror the former drainage feature. Comparison of the bottom of ash contours and topographic contours indicate CCR fill may be 40 feet or greater within the former drainage feature.

The Peoria Silt and Sangamon Soils extends from beneath the topsoil to depths ranging from 3 to 46 feet. The Peoria Silt and Sangamon Soils consist predominantly of low permeability lean clay.

The Hagarstown Member of the Pearl Formation underlies the Peoria Silt and Sangamon Soils. This is a discontinuous sandy unit composed of poorly graded sand with silt, with thicknesses up to approximately 7 feet but generally the thickness is less than 2 feet.

The Hagarstown Member is generally underlain by a relatively thick till sequence consisting of the Vandalia Till. The till sequence is encountered at thicknesses up to 59 feet in the area of the PAP, while the average thickness is 26 feet. This thick glacial deposit is laterally continuous beneath the NPP. The Vandalia Till primarily consists of lean clay and silty clay. Alluvial deposits belonging to the Cahokia Formation, which is a Holocene stage deposit in floodplains and channels of modern rivers and streams are expected to occur along the southeastern corner of the PAP. Generally, the Cahokia Formation consists of poorly sorted sand, silt, and clay with wood and shell fragments with local deposits of sandy gravel which is similar in composition to the deposits that comprise the UD and UCU.

The Mulberry Grove Member is a thin to moderately thick (3 to 17 feet) unit composed of silty sand, poorly graded sand with silt and well graded sand with silt. The Mulberry Member generally slopes from approximately 483 feet NAVD88 in the northeast portion of the PAP to 462 feet NAVD88 in the southwest portion of PAP. The maximum observed thickness of this member was 30 feet, while the average thickness is approximately 10 feet.

Till sequences underlying the Mulberry Grove Member consist of clay and silt of the Smithboro Till Member and Banner Formation. These laterally continuous till units are encountered at thicknesses up to 36 feet, while the average thickness is 32 feet. The till sequences are typically composed of lean clay and silty clay.

The Pennsylvanian Age Mattoon Formation consists of a complex sequence of thin limestones, coals, black fissile shales, underclays, thick gray shales, and several well-developed sandstones. The bedrock is dipping to the southwest at NPP.

2.2 Hydrogeology

Five distinct hydrostratigraphic units have been identified at NPP based on stratigraphic relationships and common hydrogeologic characteristics, which are summarized below:

- **UD/PMP:** this unit includes the lower permeability silts and clays of the Peoria Silt and Sangamon Soil, and the sandier soils of the Hagarstown Member (*i.e.,* PMP). These units are hydraulically connected and underlain by a thick till sequence of Vandalia Till.
- **UCU:** underlying the UD till sequence, the laterally continuous low permeability silts and clays of the Vandalia Till and Cahokia Formation are 26 feet thick on average.
- **UA:** this unit consisting of sands and gravels of the Mulberry Grove Formation is on average 10 feet thick and can be up to 30 feet thick. These sandy deposits are the first laterally continuous sands observed beneath the PAP.
- **LCU:** underlying the UA are the low permeability silts and clays of the Smithboro Till and the Banner Formation. This unit is approximately 5 to 36 feet thick.
- **BCU:** The low permeability bedrock underlying the PAP is the Pennsylvanian Age Mattoon Formation, which consists of a complex sequence of thin limestones, coals, black fissile shales, underclays, thick gray shales, and several well-developed sandstones. The Mattoon Formation has a maximum thickness of more than 600 feet in the central part of the Illinois Basin in Jasper County.
- Holocene alluvial deposits of the Cahokia formation are expected to replace UD and UCU deposits along the southeastern boundary of the PAP.

2.2.1 Groundwater Flow

Monitoring well locations are illustrated in **Figure 2-1**. The elevations of water within the PAP (as observed in XPW01 through XPW04 and XSG01) are greater than the surrounding areas (**Figures 2-2** and **2-3**). Note that XPW01 through XPW04 were removed in 2024 to make operational changes within the PAP. The phreatic surface within the PAP between February and August 2021 averaged 542 feet NAVD88, ranging from 546.69 feet NAVD88 in XPW02 (located along the northern portion of the PAP) to 535.40 feet NAVD88 in XSG01 (located along the southern portion of the PAP). Groundwater elevations in PMP wells are above those in the UA and range from approximately 518 feet NAVD88 (APW05S) to 535 feet NAVD88 (APW05S).

Groundwater flow in the UA is generally from north to south. However, the UA wells also display flow converging towards a former surface drainage feature located west of the PAP (**Figure 2-2** and **Figure 2-3**) and an area where the UA has the greatest thickness. Groundwater elevations vary seasonally, generally less than one foot per year, while across the PAP they range from approximately 490 to 530 feet NAVD88, although flow directions are generally consistent.

2.2.2 Hydraulic Properties

Hydraulic field tests were conducted on multiple wells within the CCR, UD, PMP, and UA at NPP and are summarized below:

- Hydraulic properties for the CCR ranged from 1.0×10^{-3} to 2.3×10^{-1} centimeters per second (cm/s) (2.8 to 652 feet per day [ft/d]), with a geometric mean hydraulic conductivity of 2.0×10^{-2} cm/s (56.7 ft/d), based on hydraulic tests on four wells.
- Hydraulic field tests conducted on three wells provided hydraulic properties of the UD unit, which ranged from 5.14×10^{-6} to 4.53×10^{-5} cm/s (0.01 to 128.4 ft/d) with a geometric mean of 1.5×10^{-5} cm/s (0.04 ft/d).
- Hydraulic properties for the PMP ranged from 6.1×10^{-4} to 1.5×10^{-2} cm/s (1.7 to 42.5 ft/d) with a geometric mean hydraulic conductivity of 3.1×10^{-3} cm/s (8.8 ft/d), based on hydraulic tests on two wells.
- Hydraulic properties for the UA ranged from 2.0×10^{-4} to 1.5×10^{-1} cm/s (0.57 to 425.0 ft/d) with a geometric mean of 6.8×10^{-3} cm/s (19.3 ft/d), based on field tests conducted on seven wells.

The absence of wells screened within the UCU, LCU, and BCU at the NPP means that no field based hydraulic data are available for these units.

Additional laboratory analysis of samples from the CCR, UD, PMP, UCU, UA, and LCU provided vertical hydraulic conductivities summarized below:

- Laboratory falling head permeability test results for the six CCR samples indicated a geometric mean vertical hydraulic conductivity of 3.1×10^{-4} cm/s (0.88 ft/d) with a range of 1.6×10^{-5} to 1.3×10^{-3} cm/s (0.05 to 3.7 ft/d).
- Laboratory falling head permeability test results in the UD indicated a geometric mean vertical hydraulic conductivity of 5.9×10^{-8} cm/s (0.0002 ft/d) and ranged from 3.1×10^{-8} to 8.6×10^{-8} cm/s (0.0001 to 0.00024 ft/d). These values are less than previous samples collected in 2017, with a geometric mean hydraulic conductivity of 1.3×10^{-5} cm/s (0.04 ft/d) (Natural Resource Technology, Inc., an OBG Company [NRT/OBG], 2017).
- Laboratory falling head permeability test results from three samples collected from the Hagarstown Member (*i.e.,* PMP) within the UD, indicated a geometric mean vertical hydraulic conductivity of 3.5×10^{-5} cm/s (0.1 ft/d) and ranged from 1.1×10^{-7} to 9.6×10^{-5} cm/s (0.0003 to 0.27 ft/d).
- Laboratory falling head permeability test results from four samples collected from the Vandalia Till indicated that the UCU has a geometric mean vertical hydraulic conductivity of 6.7×10^{-8} cm/s (0.0002 ft/d) and ranged from 3.3×10^{-8} to 9.7×10^{-8} cm/s (0.0001 to 0.0003 ft/d).
- Laboratory falling head permeability test results from five samples collected from the Mulberry Grove Formation indicated that the UA has a geometric mean vertical hydraulic conductivity of 3.2×10^{-4} cm/s (0.9 ft/d) and ranged from 3.5×10^{-6} to 7.2×10^{-4} cm/s (0.01 to 2.04 ft/d) (NRT/OBG, 2017).
- Laboratory falling head permeability test results from eight samples collected from the glacial tills of the Smithboro Till indicated a geometric mean vertical hydraulic conductivity of 9.3×10^{-8} cm/s (0.0003 ft/d) and ranged from 2.4×10^{-8} to 2.7×10^{-7} cm/s (0.0001 to 0.0008 ft/d).

2.2.3 Groundwater Elevation Data

There are 30 wells located around the PAP with most wells located adjacent to the perimeter of the PAP. In most of these wells, water level measurements are available from 2015 to 2021. The well construction details are summarized in **Table 2-1** and groundwater elevation readings are summarized in **Table 2-2**. The observed range in groundwater elevation (GWL) within the PMP wells data set is 17.3 feet and 44.3 feet in the UA wells. For all wells, the mean variation in GWL within each well is 0.8 feet (mean GWL variation), with an observed minimum and maximum variation of 0.2 and 2.5 feet, respectively. The UA approaches the former land surface, now beneath Newton Lake, northeast of the PAP. The UA may intersect the base of Newton Lake allowing groundwater within the UA to mix with surface water from the lake, upgradient of the PAP. Groundwater flow in the UA generally flows southwest across the PAP with potentiometric surface elevations at downgradient wells around 491 feet NAVD88 (approximately 15 feet lower than the Newton Lake elevation). The elevation of water in Newton Lake ranges from 504.42 to 504.84 feet NAVD88. This separation in groundwater and lake elevations (and observed downward vertical gradients) indicates groundwater within the UA does not flow into Newton Lake.

2.2.4 Mining Activity

The areas immediately surrounding the facility have never been mined. Based on the directory of coal mines for Jasper County (Illinois State Geological Survey [ISGS], 2021), the nearest coal mines in the vicinity of the PAP are located approximately 6.7 miles to the northeast.

3. GROUNDWATER QUALITY

3.1 Groundwater Classification

Per 35 I.A.C. § 620.210, groundwater within the UA at the PAP meets the definition of Class I – Potable Resource Groundwater based on the following criteria:

- Groundwater is located more than 10 feet below ground surface and within an unconsolidated silty sand and gravel unit which is five feet or more in thickness.
- Hydraulic conductivity exceeds the 1 x 10^{-4} cm/s criterion.
- Groundwater is not downgradient of or underlying previously mined out areas.

Testing of the unconsolidated materials of the Mulberry Grove Member averaged 21% fines, which is greater than the 12% fines criterion; however, this was not deemed prohibitive of the Class I Classification (Ramboll, 2021a).

3.2 Potential Groundwater Exceedances

There are potential groundwater exceedances of applicable GWPS attributable to the PAP as described below. Groundwater concentrations from 2015 to 2021 are presented in the HCR Table 4-1 (Ramboll, 2021a), were evaluated and summarized in the History of Potential Exceedance tables (Ramboll, 2021b), and are considered potential exceedances because the methodology used to determine them is proposed in the Statistical Analysis Plan (Appendix A to GMP; Ramboll, 2021c), which is pending approval by IEPA. The following GWPS exceedances were determined in 2024 (Ramboll, 2024a; Ramboll, 2024b; Ramboll, 2024c; Ramboll, 2025a):

- Chloride in APW15
- Lithium in APW02
- Sulfate in APW02, APW04, APW05S, and APW10
- TDS in APW02, APW04, APW05S, and APW12

An Alternative Source Demonstration ASD was completed on October 6, 2023 for the chloride GWPS exceedance detected at monitoring well APW15 during the Quarter 2, 2023 sampling event.

4. GROUNDWATER MODEL

4.1 Overview

Data collected at NPP from 2004 to the recent 2021 field investigation were used to construct a groundwater model of the PAP. The model was then used to evaluate how the proposed closure options (CIP and CBR) would achieve compliance with the applicable groundwater standards following the closure construction. The modeling results are summarized and evaluated in this GMR. The associated model files are included as **Appendix B**.

4.2 Conceptual Model

The HCR (Ramboll, 2021a) forms the foundation of the PAP hydrogeological setting. The PAP overlies the recharge area for the underlying transmissive geologic media, which are composed of unlithified deposits.

4.2.1 Hydrogeology

As discussed in **Section 2.2**, groundwater flow around the PAP is generally in a southwest direction. The silts of the UD and sands of the PMP are hydraulically connected. The groundwater flow in the silts and clays of the UD and confining units of the UCU, LCU, and BCU are expected to be primarily vertical. The Hagarstown member PMP and sands of the UA are where the majority of the horizontal migration is expected to occur. The geological conceptual model for NPP consists of the following layers:

- Silts and Clays (UD) – silt and clayey silt of the Peoria Silt and Sangamon Soil which extends beneath the topsoil.
- Discontinuous sands (PMP) - sandier soils of the Hagarstown Member.
- Vandalia Till (UCU) – a thick layer of low permeability till consisting of the Vandalia Till.
- Sands (UA) – sands and gravels of the Mulberry Grove Formation, laterally continuous sand and gravel deposit identified beneath NPP.
- Smithboro Till (LCU) – composed of lean clay Smithboro Till and Banner Formation.
- BCU – lowermost unit identified at NPP and underlies all unlithified deposits. This unit, composed of low permeability shale of the Mattoon Formation.
- Alluvial deposits of the Cahokia formation may replace UD and UCU deposits along the southeastern boundary of the PAP.

Surfaces for each of the six major geological units (Silts/Clays, discontinuous sand, Vandalia Till, shallow sand, Smithboro Till, and Bedrock) were made by interpolating contacts between the units interpreted from boring logs. Alluvial deposits of the Cahokia formation were represented by zones within the horizontal layers of the major geologic units. Boring log information is centered around the pond and CCR units; the surfaces were extended to the full model domain by extrapolation and verified with off-site well logs, where available.

4.2.2 Extent and Boundaries

The United States Geological Survey (USGS) National Map places the NPP within the upper Illinois-Little Wabash watershed subbasin (Hydrologic Unit Code 05120114).

The PAP CSM extent is bounded by a hydrological catchment (watershed) divide to the east based on watershed data from USGS. Along the north, south, and east the model boundary has been placed along known waterbodies as much as possible. As such, it is assumed groundwater inflow from adjacent watersheds is negligible through both the UA and LCU.

The Newton Lake water levels are managed such that they remain at an elevation between 504.23 and 504.82 feet NAVD88. Newton Lake is the receiving body of water for surface water in the area encompassed by the CSM.

Infiltration of precipitation to the groundwater table is applied as recharge at NPP. Groundwater in the UD migrates downward into the discontinuous sands of the Hagarstown Formation. As discussed in **Section 2.2.1**, the Hagarstown Formation is considered a PMP for groundwater adjacent to the PAP. The sands of the UA are separated from the Hagarstown Formation PMP and the base of ash in the PAP by the laterally continuous UCU. The UA receives water from connection with Newton Lake.

4.2.3 Primary Ash Pond

The PAP is constructed with an earthen berm which acts as a low permeability interface between the CCR contained within the PAP and the ambient groundwater system. Findings from the HCR (Ramboll, 2021a) indicate that the PAP does not appear to impact groundwater flow directions in the UA via recharge to groundwater. The PAP does influence the shallower UD/PMP flow system, where there is a component of radial flow from the pond to the thin Hagarstown Formation.

Sulfate was selected for transport modeling. Sulfate is commonly used as an indicator parameter for contaminant transport modeling for CCR because: (i) it is commonly present in coal ash leachate; and (ii) it is mobile and typically not very reactive but conservative (*i.e.*, low rates of sorption or degradation) in groundwater. The surrogates selected for groundwater flow and transport modeling are conservative parameters (*i.e.,* aqueous concentrations are predominantly affected by physical processes such as dilution and dispersion rather than by chemical attenuation mechanisms) and therefore represent the maximum plume extent. The use of a conservative parameter to represent plume extent and clean-up times is consistent with United States Environmental Protection Agency (USEPA) modeling examples intended for evaluating relative remedy effectiveness[2].

4.3 Model Approach

Comparisons of observed lithium and TDS concentrations to sulfate (Figure A and Figure B, respectively, below) indicate statistically significant correlations between these parameters in UD wells where these potential exceedances were observed. Observed concentrations were transformed into Log10 concentrations for evaluation. The correlation coefficient (R2) and probability (p) values (indicator of statistical significance) are also provided on **Figure A** and **Figure B**. Higher R2 values (*i.e.*, closer to 1) indicate stronger correlation between parameters. A correlation is considered statistically significant when the p value is lower than 0.05. Both correlations have p values less than the target of 0.05, indicating correlations are statistically significant. The correlations are strongest between sulfate and TDS. The statistically significant correlations associated with sulfate concentrations indicate sulfate is an acceptable surrogate for

[2] USEPA. 1994. Ground-Water Modeling Compendium. Second Edition. Office of Solid Waste and Emergency Response. 500-B-94-004. July.

lithium and TDS in the groundwater model, and concentrations of these parameters are expected to change along with model predicted sulfate concentrations.

Figure A. Sulfate Correlation with Lithium in UD Wells

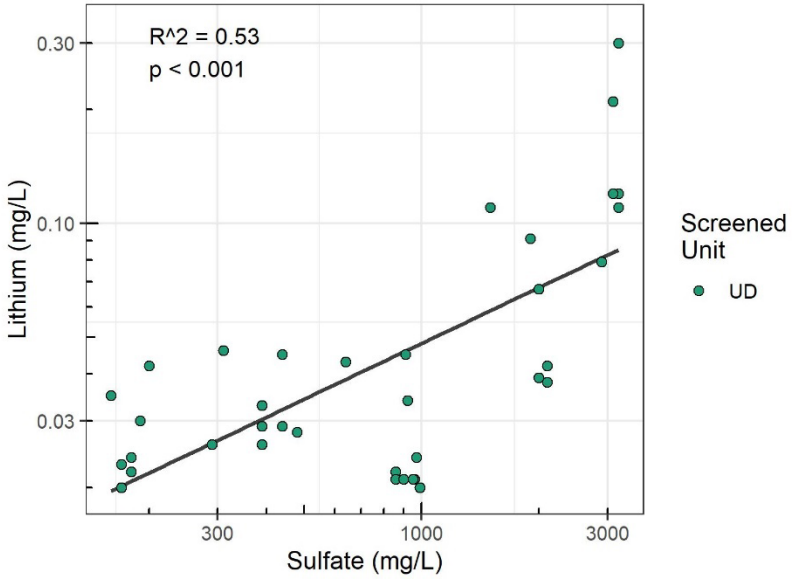

Figure B. Sulfate Correlation with TDS in UD Wells

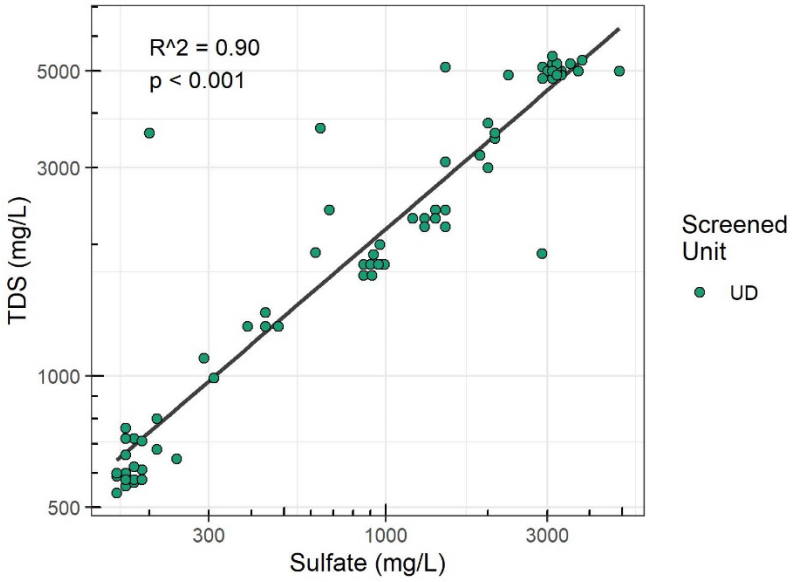

A three-dimensional groundwater flow model was calibrated to represent the conceptual flow system described above. A steady state model was used to simulate the mean groundwater flow conditions at NPP. The model was calibrated to match mean groundwater elevations observed between 2015 to 2021 (**Table 2-2**). Prediction simulations were then performed to evaluate the

potential impacts to groundwater from CIP as presented in the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, 2025) which is an appendix to the Construction Permit Application to which this report is also attached. **Figure 4-1** shows the calibration and predictive modeling timeline.

Three model codes were used to simulate groundwater flow and contaminant transport:

- Groundwater flow was modeled in three dimensions using MODFLOW 2005.
- Contaminant transport was modeled in three dimensions using MT3DMS.
- Percolation (recharge) was modeled using the results of the Hydrologic Evaluation of Landfill Performance (HELP) model.

5. MODEL SETUP AND CALIBRATION

5.1 Model Descriptions

For the construction and calibration of the numerical groundwater flow model for NPP, Ramboll selected the model code MODFLOW, a publicly-available groundwater flow simulation program developed by the USGS (McDonald and Harbaugh, 1988). MODFLOW is thoroughly documented, widely used by consultants, government agencies and researchers, and is consistently accepted in regulatory and litigation proceedings. MODFLOW uses a finite difference approximation to solve a three-dimensional head distribution in a transient, multi-layer, heterogeneous, anisotropic, variable-gradient, variable-thickness, confined or unconfined flow system—given user-supplied inputs of hydraulic conductivity, aquifer/layer thickness, recharge, wells, and boundary conditions. The program also calculates water balance at wells, rivers, and drains.

MODFLOW was developed by USGS (McDonald and Harbaugh, 1988) and has been updated several times since. Major assumptions of the code are: (i) groundwater flow is governed by Darcy's law; (ii) the formation behaves as a continuous porous medium; (iii) flow is not affected by chemical, temperature, or density gradients; and (iv) hydraulic properties are constant within a grid cell. Other assumptions concerning the finite difference equation can be found in McDonald and Harbaugh (1988). MODFLOW 2005 was used for these simulations with Groundwater Vistas 7 software for model pre- and post- processing tasks (Environmental Simulations, Inc., 2017).

MT3DMS (Zheng and Wang, 1998) is an update of MT3D. It calculates concentration distribution for a single dissolved solute as a function of time and space. Concentration is distributed over a three-dimensional, non-uniform, transient flow field. Solute mass may be input at discrete points (wells, drains, river nodes, constant head cells), or distributed evenly or unevenly over the land surface (recharge).

MT3DMS accounts for advection, dispersion, diffusion, first-order decay, and sorption. Sorption can be calculated using linear, Freundlich, or Langmuir isotherms. First-order decay terms may be differentiated for the adsorbed and dissolved phases.

The program uses the standard finite difference method, the particle-tracking-based Eulerian-Lagrangian methods and the higher-order finite-volume total-variation-diminishing (TVD) method for the solution schemes. The finite difference solution has numerical dispersion for low-dispersivity transport scenarios but conserves good mass balance. The particle-tracking method avoids numerical dispersion but was not accurate in conserving mass. The TVD solution is not subject to significant numerical distribution and adequately conserves mass, but is numerically intensive, particularly for long-term models such as developed for the PAP. The finite difference solution was used for this simulation.

Major assumptions of MT3DMS are: (i) changes in the concentration field do not affect the flow field; (ii) changes in the concentration of one solute do not affect the concentration of another solute; (iii) chemical and hydraulic properties are constant within a grid cell; and (iv) sorption is instantaneous and fully reversible, while decay is not reversible.

The HELP model was developed by the USEPA. HELP is a one-dimensional hydrologic model of water movement across, into, through and out of a landfill or soil column based on precipitation, evapotranspiration, runoff, and the geometry and hydrogeologic properties of a layered soil and

waste profile. For this modeling, results of the HELP model, HELP Version 4.0 (Tolaymat and Krause, 2020) completed for the groundwater model were used to estimate the hydraulic flux from beneath the PAP.

5.2 Flow and Transport Model Setup

The modeled area was approximately 7,900 feet by 9,950 feet (382,955,000 square feet [ft^2]) with the PAP located in the southern quadrant (**Figure 5-1**). The model boundaries along the northern, southern, and eastern edges of the model were selected to maintain sufficient distance from the PAP to reduce boundary interference with model calculations, while not extending too far past the extent of available calibration data. The east and west edges of the model also approximate topographic highs, surface water divides, watershed boundaries.

The MODFLOW model was calibrated to mean groundwater elevation collected from 2015 to 2021 presented in **Table 2-2**. MT3DMS was run on the calibrated flow model and model-simulated concentrations were calibrated to observed sulfate concentration values at the monitoring wells from March to July 2021 presented in **Table 2-2**. Multiple iterations of MODFLOW and MT3DMS calibration were performed to achieve an acceptable match to observed flow and transport data. For the PAP, the calibrated flow and transport models were used in predictive modeling to evaluate the CIP and CBR closure scenarios. Prior to simulation of CIP and CBR, a dewatering phase, which simulated the removal of liquids from the CCR material in the PAP was completed. Closure scenarios were simulated by removing saturated ash cells and using HELP modeled recharge values to simulate changes proposed in the closure scenarios.

5.2.1 Grid and Boundary Conditions

A seven-layer, 451 x 508 node grid was established with a variable grid spacing of between 25 and 100 feet (**Figure 5-2 through Figure 5-8**), with a total number of 1,546,703 active cells. The grid is rotated 25 degrees to the east to align the model boundary with the orientation of Newton Lake and Sandy Creek.

The northern boundaries for layers 1, 2, 3, and 4 are general head boundaries placed to simulate flow in the Peoria Silt, Sangamon Soil, and sandier soils of the Hagarstown Member composing the UD, PMP, and UCU. The general head boundaries along the northern and southern model boundaries for layer 6 represents the regional flow conditions within this unit. The eastern and western edges are no flow boundaries in all model layers.

Newton Lake is represented as a constant head boundary based on a reasonably constant surface water elevation measured from February 15 to March 9, 2021 of between 504.42 to 504.84 feet NAVD88. The constant head boundary was simulated with an elevation equal to 504.6 feet. The lake is in hydraulic connection with multiple layers within the model.

The bottom of the model was also a no-flow boundary. The top of the model was a time-dependent specified flux boundary, with specified flux rates equal to the recharge rate. A specified mass flux boundary was used to simulate downward percolation of solute mass from the PAP. This boundary condition assigns a specified concentration to recharge water entering the cells within the PAP, and the resulting concentration in the PAP cells is a function of the relative rate and concentration of recharge water (water percolating from the impoundments) compared to the rate and concentration of other water entering the node.

Natural (streams) drainage features are present in the modeled area; these are represented as rivers and drains depending on available information in the model.

5.2.2 Flow Model Input Values and Sensitivity

Evaluation of monitoring well data for the PAP has not identified statistically significant seasonal trends in groundwater flow or quality which could affect model applicability for prediction of transport. The MODFLOW model was calibrated to mean groundwater elevations from 2015 to 2021. Multiple iterations of MODFLOW calibration were performed to achieve an acceptable match to observed flow data.

Sensitivity analysis was conducted by changing input values and observing changes in the sum of squared residuals (SSR). Horizontal conductivity, vertical conductivity, and river and general head conductance terms were all varied by one order of magnitude (*i.e.*, between one-tenth and ten times) of the calibrated values. Recharge terms were varied between one-half and two times calibrated values. River stage and drain bottom elevations were obtained from the 10-meter Digital Elevation Model (DEM) from the United States Department of Agriculture/Natural Resources Conservation Service National Geospatial Center of Excellence (USDA/NRCS, 2022). The vertical error of the 10-meter DEM is 0.82 meters (2.7 feet); therefore, the stream stage and drain bases were varied by adding and subtracting 2.7 feet. General head boundary head terms were varied between 90 and 110 % of calibrated values. When the calibrated model was tested, the SSR was 794. Sensitivity test results were categorized into negligible, low, moderate, moderately high, and high sensitivity based on the change in the SSR as summarized in the notes in **Table 5-1**.

5.2.2.1 Layer Top/Bottom

A digital elevation model of the area was used to assign the top of layer one. The elevations for the base of each hydrostratigraphic layer were interpolated from boring log data primarily from logs provided in the HCR (Ramboll, 2021a) utilizing Surfer® software for each of the six distinct water-bearing units described in **Section 2** (excluding the BCU). The resulting surfaces were imported into MODFLOW. The silts, clays, and sands of the UD unit (Peoria Silt, Sangamon Soil and Hagarstown Member) were divided into three layers to accommodate the explicit inclusion of the PAP ash deposits and the PMP. The thick UCU comprised of Vandalia Till was divided into two layers for contaminant transport; the Mulberry Grove Formation and Smithboro Till were represented as single layers within the model. **Figures 5-9** to **Figure 5-15** show the seven model layer elevations. The resulting surfaces were imported as layers into the model to represent the distribution and change in thickness of each water-bearing unit across the model domain. Flow model layer descriptions are summarized in **Table A** below.

Table A. Flow Model Layer Descriptions

Layer	Hydrostratigraphic unit name	Hydrostratigraphic unit used to determine layer thickness	Top Elevation [1]	Bottom Elevation [1]	Thickness (feet)
			Mean (Minimum – Maximum)		
1&2	UD	Silty clay and clay	535.6 (503.71-564.0)	511.1 (472.0-532.5)	24.5 (4.0-76.4)
3	PMP	Sand, silty clay, and clay	511.1 (472.0-532.5)	508.8 (470.0-530.1)	2.3 (2.0-25.56)
4&5	UCU	Silts and lean clays of the Vandalia member	508.8 (470.0-530.1)	472.0 (425.4-486.9)	36.8 (10.7-57.6)
6	UA	Sands and gravels within silty clay	472.0 (425.4-486.9)	465.3 (418.1-483.9)	6.7 (2.0-29.9)
7	LCU	lean clays of the Smithboro Till	465.3 (418.1-483.9)	438.3 (412.2-458.1)	26.9 (5.9-37.8)

Notes:
[1] Elevation is measured in feet, referenced to NAVD88.

5.2.2.2 Hydraulic Conductivity

Hydraulic conductivity values and sensitivity results are summarized in **Table 5-1.** The spatial distribution of the hydraulic conductivities within the UD, UCU, and LCU was considered homogenous. A zone representing the Cahokia deposits was included in UCU layers 4 and 5. The hydraulic properties of this zone are equivalent to those of the rest of the UCU and this zone is discussed further in **Section 5.2.3.5**. In both the PMP and UA layers (model layers 3 and 6, respectively), well log data indicated the presence of silt, sand, and gravel lenses. These were included in the model as zones within these two layers. The spatial extent of these zones was determined using well log data for areas of silt within the PMP, and silt/sand and gravel within the UA. Hydraulic properties within these zones do not vary. **Figures 5-16 through 5-22** show the spatial distribution of the hydrostratigraphic units, PAP, and other units at NPP for each of the seven model layers.

Where available, hydraulic conductivity values were derived from field measured or laboratory tested values reported in the HCR (Ramboll, 2021a) (**Section 2.2.2**). No horizontal anisotropy was assumed. Vertical anisotropy (Kh/Kv) was applied to conductivity zones to simulate preferential flow in the horizontal direction in these materials and is presented in **Table 5-1**.

The model was highly sensitive to changes in horizontal conductivity in UD (zone 1), UD-PMP sand (zone 5), UA (zone 7), UA-gravel (zone 9), and moderately high sensitivity to the sand deposit in the UA (zone 8). The calibrated model has low to moderate sensitivity to horizontal conductivity in the remaining hydrostratigraphic units. The model was highly sensitive to changes in the vertical conductivity in the UD (zone 1), and the UCU and UCU-Cahokia (zone 6 and 11, respectively). The model had a moderately high sensitivity to changes in vertical conductivity in the UA (zone 7) and the sand deposit in the UA (zone 8), and moderate sensitivity to changes in vertical conductivity in UD-PMP sand (zone 5) and UA-gravel (zone 9). The UD fill (zone 2), CCR (zone 3), UD-PMP (zone 4), and LCU (zone 10) exhibited low sensitivity.

5.2.2.3 Recharge

Recharge rates were determined through calibration of the model to observed groundwater elevations. For the calibration model, recharge was applied to the upper most active layer and the rates varied based on different units, namely the PAP, LF1, LF2, Secondary Pond, NPP, and Cooling Pond. Model inputs are summarized in **Table 5-1**. The distribution of recharge is shown in **Figure 5-23**.

The calibrated flow model is highly sensitive to recharge to the PAP, moderately sensitive to recharge to the UD, and has negligible sensitivity to all other zones within the model (**Table 5-1**).

5.2.2.4 Storage and Specific Yield

The flow calibration model did not use these terms because it was run at steady state. For the transport model, which was run as a transient simulation, no field data defining these terms were available so published values were used consistent with Fetter (1988). Specific yield was set to equal effective porosity values described in **Section 5.2.3.3**. The spatial distribution of the storage and specific yield zones were consistent with those of the hydraulic conductivity zones. The sensitivity of these parameters was tested by evaluating their effect on the transport model as described in **Section 5.2.3.4**.

5.2.2.5 General Head Boundary Parameters

General head boundary conditions (GHB) were used along the northern boundary of the model for layer 1 through 4 and layer 6. GHB were also used along the southern boundary for layer 6 only (**Figures 5-2** to **5-7**). The GHB at the northern limit of the model in layers 1 through 4 was used to simulate groundwater flow into the model via the UD, PMP, and UCU. The UCU was included in the GHB due to its hydraulic connection to Newton Lake even though it has a low hydraulic conductivity. The groundwater levels used for the northern boundary of the model in layers 1 through 4 were estimated using the Dupuit equation for steady state flow in an unconfined aquifer with recharge.

The DEM of NPP provided estimates of the surface water levels for Newton Lake on the east of the model domain (504.6 feet) and the Sandy Creek (525 feet) located 6,500 feet west of Newton Lake. The calibrated ambient recharge to the UD was used in the calculation of the groundwater level distribution at the northern boundary. The hydraulic conductivity value K used in the Dupuit equation was estimated during model calibration.

This GHB was only applied to cells along the northern boundary where the base of the cell was below the calculated groundwater head for a given distance from the constant head boundaries, the head was determined by the Dupuit equation. Cell conductance was then calculated using the calibrated hydraulic conductivity and the cells' saturated thickness and cell width.

The CSM for NPP (layer 6) describes a potential hydraulic connection between the UA and either Big Muddy Creek or Newton Lake dam, both of which are located approximately 14,000 feet southwest of the model domain. The elevation of both Big Muddy Creek and Newton Lake dam at this distance is approximately 460 feet. Therefore, the GHB elevation and distance at the southern limits of the model in the UA was set to 460 feet and 14,000 feet. The conductance was determined using the cells calibrated hydraulic conductivity, cell width and thickness (cells were assumed to be fully saturated).

The GHB elevation for northern boundary in the UA was established during calibration (**Table 5-1**). The distance to the GHB head was set to 1, and the GHB conductivity was calculated using the cell width, cell thickness, and calibrated hydraulic conductivity from the model.

The sensitivity to changes in specified head was negligible to moderate for both the northern GHB in layer 1-4, and in the UA (layer 6), and high for the southern GHB in the UA. The flow calibration model had low sensitivity to changes in the conductance for both the northern GHBs (layer 1-4 and layer 6), and high sensitivity in the southern GHB in layer 6 (UA).

5.2.2.6 River Parameters

The Cooling Flume transports water from the Cooling Pond north of the PAP to Newton Lake. The flume consists of three sections, where the surface water elevation is controlled via weirs with decreasing elevation as the flume approaches Newton Lake. The most upstream section is maintained at 530.98 feet, the intermediate section has a surface water elevation of 515.66 feet, and the surface water elevation in the final section is maintained at 499.0 feet. Sandy Creek is the primary natural surface water feature which discharges into Newton Lake west of the PAP. A summary of river and drain boundary lengths and slopes is provided in **Table B** on the next page.

Both the Cooling Flume and Sandy Creek are included in the model as head dependent flux boundaries that required inputs for elevation of the surface water, bottom of the stream, width, bed thickness, and bed hydraulic conductivity (**Table 5-1**). A total of three river reaches are included in the model; in the absence of river geometry information the DEM was used to estimate stream stage at the upstream and downstream limits of each reach. For Sandy Creek the slope of the river was then linearly interpolated along the reach, providing an estimation of stream stage along the length of each reach for each model grid cell though which the river flows. Bed thickness was set at 1 foot and river width was set at 10 feet.

The width of the Cooling Flume (approximately 32 feet) is larger than the grid cell dimensions (25 feet by 25 feet), therefore the conductance term for the Cooling Flume was based on the area of the cells which coincide with the flume. The DEM provided surface water elevation estimations of the three sections of the Cooling Flume, and the bed thickness was set to 1 foot.

River width, bed thickness, and bed hydraulic conductivity parameters were used to calculate a conductance term for the river cells. This conductance term was determined by adjusting hydraulic conductivity during model calibration.

The river boundaries were placed in layers 1 through 4, corresponding with simulated river elevation and base of the river (**Figure 5-2 through Figure 5-5**). The calibrated flow model has negligible sensitivity to changes in either river stage or conductance.

Table B. River and Drain Information

Name	Boundary Type	Length (feet)	Slope (ft/ft)
Cooling Flume	River	7,891.0	-
Sandy Creek	River	13,082.7	-0.0019
Sandy Creek Tributary 1	Drain	2,420.5	-0.0076
Sandy Creek Tributary 2	Drain	6,326.4	-0.0038
Sandy Creek Tributary 3A	Drain	4,359.1	-0.0015
Sandy Creek Tributary 3B	Drain	4,088.8	-0.0058
Landfill Stream	Drain	2,706.7	-0.0057
PAP Stream	Drain	5,658.5	-0.0038
PAP drain north	Drain	2,055.2	-0.0102
Newton Lake Tributary 1	Drain	6,854.6	-0.0057
Newton Lake Tributary 2	Drain	3,414.8	-0.0083
Newton Lake Tributary 3	Drain	2,369.0	-0.0090
Newton Lake Tributary 4	Drain	1,603.0	-0.0029
Newton Lake Tributary 5	Drain	2,448.4	-0.0078
Newton Lake Tributary 6	Drain	2,556.7	-0.0107
Newton Lake Tributary 7	Drain	3,002.7	-0.0061
Tributary South 1	Drain	1,839.0	-0.0021
Tributary South 2	Drain	4,364.0	-0.0041
Tributary South 3	Drain	1,200.9	-0.0083
PAP drain north	Drain	2,051.2	-0.0137

Notes:
ft/ft = feet per foot

5.2.2.7 Drains

The model contains numerous small tributaries which discharge into both Sandy Creek and Newton Lake. Limited hydrological data are available for these surface water features; therefore, it is uncertain how these interact with the groundwater levels. However, these features are all first-order streams (or headwater streams) and therefore it is highly likely that they are fed by a combination of groundwater discharge and surface runoff (Horton, 1945). Therefore, these streams are included in the model as head dependent flux boundaries (drain) that required inputs for elevation of the bottom on the stream, width, bed thickness, and bed hydraulic conductivity (**Table 5-1**). By using the drain head-dependent flux boundary it is assumed that these streams only act as groundwater discharge features and makes the fewest assumptions regarding stream geometry.

A total of 18 drain reaches are included in the model. In the absence of river geometry information, the DEM was used to estimate stream stage at the upstream and downstream limits of each reach. The slope of the river was then linearly interpolated along the reach, which provided an estimate of stream stage along the length of each reach for each model grid cell though which the stream flows. A summary of river and drain boundary lengths and slopes is

summarized in **Table B** above. The drain boundaries were placed in layers 1 through 4 corresponding with simulated drain depth (**Figure 5-2 through Figure 5-5**).

The calibrated flow model has negligible to low sensitivity to both drain elevation and conductance for most drains. Only the Landfill drain (reach 6) had moderate sensitivity to drain elevation.

5.2.3 Transport Model Input Values and Sensitivity

MT3DMS input values are listed in **Table 5-2** and described below. Sensitivity of the transport model is summarized in **Table 5-3**.

Groundwater transport was calibrated to groundwater sulfate concentration ranges at each well as measured from the monitoring wells between 2015 (where available) and 2021. The transport model calibration targets are summarized in **Table 2-2**.

Sensitivity analysis was conducted by changing input values and observing percent change in sulfate concentration at each well from the calibrated model sulfate concentration. Effective porosity was varied by decreasing and increasing calibrated model values by 0.05. Storage values were multiplied and divided by a factor of 10, and specific yield by a factor of 2. Dispersivity in the Cahokia Alluvium was varied by decreasing and increasing calibrated model dispersivity by 50 percent. The transport model had a negligible sensitivity to changes in storage and specific yield (**Table 5-3**). The transport model ranged from negligible to high sensitivity to effective porosity and negligible to moderately high sensitivity to dispersivity as discussed in **Sections 5.2.3.3** and **5.2.3.5**.

5.2.3.1 Initial Concentrations

No initial concentrations were placed in the steady state flow calibration model. The flow model was run as transient, and concentration was added to the model through recharge starting at the same time as flow simulation. Modeling was performed for a sufficient period (45 years) to allow modeled concentrations in the primary transport layer (*i.e.,* UD/PMP and UA) to reach recently observed levels.

5.2.3.2 Source Concentrations

Based on review of CCR placement, initial source concentrations for the pond were set to observed concentrations from porewater samples collected from earlier placement areas (XPW02 and XPW03) with a sulfate concentration of 130 milligrams per liter (mg/L) (**Figure 5-24**). This was applied throughout the pond until 1985, after which discoloration becomes apparent in the CCR deposits and source areas were added using porewater results from XPW01 and XPW04. Three concentration sources in the form of vertical percolation (recharge) through CCR were simulated within the PAP for calibration (**Table 5-2**): (i) percolation through CCR in the northeastern portion of the PAP, (ii) percolation through CCR in the northwestern portion of the PAP, and (iii) percolation through CCR in the remaining area of the PAP (**Figure 5-24**).

Porewater chemistry from within the PAP indicated that the distribution of sulfate concentrations is spatially variable, ranging on average between 19,000 mg/L (XPW01) and 99 mg/L (XPW03). Therefore, zonation of the PAP concentration sources was used to delineate areas with differing sulfate source inputs. The zonation was based on evidence provided by Ramboll (2020) and AECOM's (2016) History of Construction of the PAP. The CCR materials within the PAP shows

zones of discoloration, suggestive of additional chemical processes occurring within the CCR and/or the presence of deposits other than CCR (Burns & McDonnell Engineering Company, Inc., 2020). Analysis of aerial imagery of the PAP indicates that the zones of discoloration around XWP01 and XPW04 are present from 1998 onwards. The CCR around XWP02 and XWP03 shows no discoloration and are located within the oldest CCR deposits. The sulfate concentration in these wells is similar and possibly more indicative of the sulfate concentrations within the CCR in general. Therefore, the CCR sulfate concentration (excluding the 2 zones) was set to the average concentration from XWP02 and XPW03 (130 mg/L).

All three source areas were simulated by assigning concentration to the recharge input. All source concentrations in the transport model were based on sulfate concentration data collected in 2021. The source concentrations applied to the recharge zones and saturated ash cells immediately below the recharge zones have the same concentration values. Because these are the sources of concentration in the model, the model will be highly sensitive to changes in the input values. For that reason, sensitivity testing was not completed for the source values.

5.2.3.3 Effective Porosity

Effective porosity for each modeled hydrostratigraphic unit were obtained from the HCR (Ramboll, 2021a) and based on the porosity and are presented in **Table 5-2**.

The model had a negligible to high sensitivity to changes in porosity values, not including monitoring locations where the calibration concentration was less than 10.0 mg/L (*i.e.*, AWP05, APW06, APW08, APW11, APW15, and APW16) (**Table 5-3**). For wells with calibration concentrations greater than 10.0 mg/L, the greatest sensitivity for porosity was high for the low porosity sensitivity test at monitoring locations APW07, AWP09, APW17, and APW18.

5.2.3.4 Storage and Specific Yield Sensitivity

Estimates of storage and specific yield for each modeled hydrostratigraphic unit were obtained from the HCR (Ramboll, 2021a) and based on the porosity and are presented in **Table 5-2**.

The model had a negligible sensitivity to changes in storage and specific yield values (**Table 5-3**).

5.2.3.5 Dispersivity

Physical attenuation (dilution and dispersion) of contaminants is simulated in MT3DMS. Dispersion in porous media refers to the spreading of contaminants over a greater region than would be predicted solely from the average groundwater velocity vectors (Anderson, 1979 and 1984). Dispersion is caused by both mechanical dispersion, a result of deviations of actual velocity at a microscale from the average groundwater velocity, and molecular diffusion driven by concentration gradients. Molecular diffusion is generally secondary and negligible compared to the effects of mechanical dispersion and only becomes important when groundwater velocity is very low. The sum of mechanical dispersion and molecular diffusion is termed hydrodynamic dispersion, or simply dispersion (Zheng and Wang, 1998).

Dispersivity values were applied to the entire model domain and determined during calibration. Longitudinal dispersivity was set at 1 foot. The transverse and vertical dispersivity were set at 1/10 and 1/100 of longitudinal dispersivity. The Cahokia Alluvial deposits are represented in layer 4 a distinct zone within the UCU, there is no evidence to indicate that the hydraulic properties of

this unit differ from those of the UCU; however, there is evidence that there is preferred transport through this unit. Therefore, this unit (**Figure 5-19** and **5-20**) has been included as an area of increased dispersivity. The calibrated longitudinal dispersivity for the Cahokia Alluvium was 20 feet, with the transverse and vertical dispersivity set at 1/10 and 1/100 of longitudinal dispersivity. Changes in hydraulic conductivity within this zone have negative impacts on the flow calibration in the UA. The increased dispersivity allows for migration of mass to wells where elevated sulfate concentrations have been observed and are coincident with the Cahokia deposits illustrated on Figure 2 of the HCR (Ramboll, 2021a) while preserving flow calibration.

The model had a negligible to moderately high sensitivity to changes in the Cahokia Alluvium dispersivity in wells, not including monitoring locations where the calibrated concentration was less than 10 mg/L. For wells with calibration concentrations greater than 10.0 mg/L, the greatest sensitivity for dispersivity was moderately high for the low dispersivity sensitivity test at monitoring locations APW07, APW09, APW17, and APW18.

5.2.3.6 Retardation

It was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (Kd was set to 0 mL/g), which is a conservative estimate for estimating contaminant transport times. Lithium, sulfate, and TDS transport is likely to be affected by both chemical and physical attenuation mechanisms (*i.e.*, adsorption and/or precipitation reactions as well as dilution and dispersion). Batch adsorption testing was conducted to generate site-specific partition coefficient results for lithium and sulfate (Golder, 2022b, **Appendix C**) for locations APW-04 and APW-14. Results of the testing are summarized below:

- Lithium: Calculated linear partition coefficient (K_D) values for APW-04 and APW-14 were 4.49 and 5.58 liters per kilogram (L/kg) respectively, Langmuir partition coefficient (K_L) values were 6.2×10^7 and 1.6×10^8 L/kg, respectively, and Freundlich partition coefficients (K_F) values were 135 and 230 L/kg, respectively. In Strenge and Peterson (1989), partition coefficients for lithium range from 0 to 0.8 L/kg, depending on pH conditions and the amount of sorbent present.
- Sulfate: Calculated K_D values for APW-04 and APW-14 were 3.58 and -25.6 L/kg, respectively, K_L values were -626 and -2,200 L/kg, respectively, and K_F values were 4.11 and 2.14×10^{11} L/kg, respectively. In Strenge and Peterson (1989), partition coefficients for sulfate are 0.0 L/kg, regardless of pH conditions and the amount of sorbent present.

The results from NPP samples have a high degree of variation and little correlation with the literature values provided for comparison. The potential exceedances identified in groundwater (lithium, sulfate, and TDS) are affected by natural attenuation processes in multiple ways and to varying degrees. Further assessment of these processes and how they may be applied as a potential groundwater remedy will be completed as part of future remedy selection evaluations as necessary. For the purposes of this modeling report, and as mentioned at the beginning of this section, no retardation was applied to sulfate transport in the model *(i.e.,* Kd was set to 0).

5.3 Flow and Transport Model Assumptions and Limitations

Simplifying assumptions were made while developing this model:

- Natural recharge is constant over the long term.
- Fluctuations in lake stage do not affect groundwater flow and transport over the long term.

- Hydraulic conductivity is consistent within hydrostratigraphic units and delineated zones.
- The approximate base of ash surface in the PAP was developed with HDR using soil borings and bathymetric survey results.
- Source concentrations are assumed to remain constant over time.
- Sulfate is not adsorbed and does not decay and mixing and dispersion are the only attenuation mechanisms.

The model is limited by the data used for calibration, which adequately define the local groundwater flow system and the source and extent of the plume. Since data used for calibration are near the PAP, model predictions of transport distant spatially and temporally from the calibrated conditions at the CCR units will not be as reliable as predictions closer to the CCR units and concentrations observed in 2021.

5.4 Calibration Flow Model

The groundwater model was manually calibrated to best approximate the mean groundwater elevations in 30 wells at NPP. The mean elevations used for calibration and locations of wells within the flow model are summarized in **Table 2-2**. Well locations are shown in **Figure 2-1**. This involved modifying the hydraulic conductivities of the different hydrostratigraphic units, recharge rate, and conductance of the drains, rivers, and general head boundaries within the model to minimize the difference between the mean observed groundwater elevation and simulated groundwater elevation. Where possible, the range of the parameter values used during calibration were based on observed values (*i.e.,* for the range in hydraulic conductivity estimates from the HCR). Where this was not possible, such as for the drain and general head boundary conductance, the range of parameter values were based on other site information or inferred from knowledge from similar sites. Where data were limited, the parameter values were less constrained during calibration (*e.g.,* parameter values had wider ranges). The root mean squared error (RMSE) was used as a metric to identify the optimal values for the different parameters.

5.5 Calibration Flow Model Results

Results of the MODFLOW modeling are presented below. The model files accompany this report (**Attachment A**). **Table 5-1** shows the calibrated hydraulic conductivity for the different units shown in **Figures 5-16** to **5-22**.

Groundwater model calibration results are presented in **Figure 5-25** and **Figure 5-26**, which shows the observed GWL and simulated groundwater elevations and the observed GWL versus residuals. The near-linear relationship between observed and simulated values presented on **Figure 5-25** indicates that the model adequately represents the calibration dataset. The RMSE of the GWL across all wells was 5.14 feet. The mass balance error for the flow model was 0.00% and the ratio of the residual standard deviation to the range of heads was 9.2%, which is just below the desired target value of 10%. Another flow model calibration goal is that residuals are evenly distributed such that there is no bias affecting modeled flow. The observed heads are plotted versus the simulated heads in Figure **5-26** and simulated values are evenly distributed above and below observed values. The residual mean was also near zero with a value of 1.12 feet, indicating a small bias towards overestimating the GWL in the calibrated model; this is also illustrated in the observed versus residuals plot in **Figure 5-26**. The simulated groundwater elevations within the UD/PMP (layer 3) and the UA (layer 6) are shown in **Figure 5-27** and **Figure 5-28**.

In general, the model is able to simulate the groundwater flow patterns the UA (**Figure 2-2** and **Figure 2-3**) interpreted from the NPP well data for May and July 2021 respectively. The notable exceptions are 1) those wells located to the north of the PAP, close to the boundary between the UA and UA- sand, and 2) those wells to the east of the PAP close to the boundary between the UA, UA-sand and UA-gravel. The groundwater level is underestimated in both of these areas. The underestimation in groundwater heads suggests that the subsurface heterogeneity (the uppermost aquifer is located in glacial deposits that grade from sand to silt with gravel deposits) is not optimally represented by the zoned layers used in the model. The interpretation of both the UA-sand and UA-gravel areas were based on well log data available near the PAP. These sand and gravel deposits may or may not be present beyond the available well information. Based on the objective of the model to estimate potential impacts from the PAP, and the model's ability to simulate flow within the UA, the zoned representation in hydraulic properties within the UA is suitable.

5.6 Transport Model Results

The range of observed sulfate concentrations for transport calibration locations are summarized in **Table 2-2**. The goals of the transport model calibration were to have predicted concentrations fall within the range of observed concentrations; and, to have predicted concentrations above and below the GWPS for sulfate (400 mg/L) match observed concentrations above or below the standard at each well.

Both these goals were achieved in three of the transport calibration location wells (**Figure 5-29**), and all but two wells achieved the second goal of matching observed concentrations above or below 2 mg/L. Deviations from the observed ranges are discussed below.

- The model over predicts concentration in wells APW02, APW04, and APW12, which are screened in the UD/PMP. The modeled and observed concentration are both above 400 mg/L, so one of the two calibration goals was satisfied.
- The model under predicts concentrations in APW05S, which is screened in the UD/PMP; however, the difference between the lower limit of the range of observed concentrations (200 mg/L) and the predicted concentration of 116.3 mg/L is small. APW05S is located upgradient of the pond and may also be influenced by other factors, notwithstanding the PAP. The modeled and minimum observed concentration are both below 400 mg/L, so one of the two calibration goals was satisfied.
- The model under predicts concentrations in APW03, which is screened in the UD/PMP; however, the difference between the lower limit of the range of observed concentrations (160 mg/L) and the predicted concentration of 128.9 mg/L is small. Both the observed and predicted concentrations are below the GWPS, so one of the two calibration goals was satisfied.
- The model slightly under predicts the concentration in APW10, which is screened in the UA. The minimum observed concentration at APW10 is 390 mg/L and simulated sulfate concentration is 340 mg/L. The modeled and minimum observed concentration are both below 400 mg/L, so one of the two calibration goals was satisfied.
- The model under predicts concentrations in APW05, APW06, APW11, APW13, APW14, APW15 and APW17 which are screened in the UA. The range in observed sulfate concentrations in these wells is very small, with an average range of 35 mg/L. The maximum observed

concentrations in these wells are 15 mg/L, 9.9 mg/L, 300 mg/L, 230 mg/L, 340 mg/L, 1 mg/L and 41 mg/L, respectively. The predicted concentrations are 0.3 mg/L, 0 mg/L, 2.5 mg/L, 85.2 mg/L, 96.8 mg/L, 9 mg/L and 87.6 mg/L for APW05, APW06, APW11, APW13, APW14, APW15 and APW17, respectively. However, observed and predicted concentrations did not exceed the GWPS, satisfying one of the calibration goals.

- The model over predicts the concentration at APW18, which is screened in the UA. The maximum observed sulfate concentration at APW18 is 26 mg/L and the simulated concentration is 87.6 mg/L, which is an overprediction of 61.6 mg/L. However, observed and predicted concentrations did not exceed the GWPS, satisfying one of the calibration goals.

The remaining calibration locations (APW07, APW09, APW16) have predicted concentrations that were within range of the observed sulfate concentration and simulated GWPS exceedances. The UD/PMP well APW02, where the highest concentrations were observed (3,200 mg/L), was also calibrated to the median concentration of the observed values in 2021, indicating the transport calibration model was able to simulate the highest observed concentrations (**Figure 5-29**). The sulfate plume at the end of the transient model simulation of 500 years for the UD/PMP is shown in **Figure 5-30.** There are no simulated exceedances in the UA at the end of the transient model; however, sulfate is approaching the GWPS of 400 mg/L near APW-10 where exceedances of the GWPS have been observed.

6. SIMULATION OF CLOSURE SCENARIOS

6.1 Overview and Prediction Model Development

Prediction simulations were performed to evaluate the effects of Closure (source control measures) for the PAP on groundwater quality. The prediction simulations evaluated changes in groundwater sulfate concentrations from Scenario 1: CIP (excavating nearly 3.6 million cubic yards of CCR and placing it in consolidated CCR footprints at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table and construction of a cover system over the remaining CCR; and, Scenario 2: CBR (removal of all CCR material from the PAP). As discussed in **Section 5.2.3.5** physical attenuation (dilution and dispersion) of contaminants in groundwater is simulated in MT3DMS, which captures the physical process of natural attenuation as part of corrective actions for both closure scenarios simulated. No retardation was applied to sulfate transport in the model (*i.e.,* Kd was set to 0) as discussed in **Section 5.2.3.6**.

Closure scenarios were simulated by initially removing liquids from the CCR material over the course of 1 year by placing constant head cells with an elevation of 520 feet above the base of the CCR material and applying zero recharge to simulate dewatering of the PAP.

HELP-calculated percolation rates, based on removal and final soil backfill grading designs also provided in the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, 2025), were applied for the different closure scenarios. HELP modeling input and output values are summarized in **Table 6-1** and described in detail below.

The CIP and CBR scenarios were simulated for a 500-year period. The following simplifying assumptions were made during the simulations:

- Removal of liquids from CCR takes place prior to the CIP and CBR closure scenarios. Constant head cells were placed within the PAP to simulate the target water elevation within the ponds; and recharge was set to zero.
- In the CIP and CBR closure scenarios, HELP-calculated average annual percolation rates were developed from a 30-year HELP model run. This 30-year HELP-calculated percolation rate remained constant over duration of the closure scenario prediction model runs following CCR dewatering period.
- Changes in recharge resulting from removal of liquid (decrease calibration model recharge rates to zero) and CCR fill removal/ final soil backfill grading (recharge rates are based on HELP-calculated average annual percolation rates) have an instantaneous effect on recharge and percolation through surface materials.
- Sulfate source concentrations were assumed to be negligible (0 mg/L) in CCR removal areas in both the CIP and CBR scenarios. The spatial distribution of CCR concentrations within the consolidation area for the CIP scenario were maintained from the initial transport simulation.
- Cap construction in CIP scenario was assumed to be completed with a cover system consisting of the following (listed from ground surface down): a vegetative cover (6 inches thick), rooting zone (18 inches thick), a 200-mil geocomposite drainage layer and a 40-mil linear low-density polyethylene geomembrane.

- The start of each closure prediction simulation was initiated at the end of the calibration model period of 45 years plus 1 year to complete removal of liquid. For example, the simulation of Scenario 1: CIP begins at 46 years (45 years for calibration plus 1 year). The prediction modeling timeline for each scenario is illustrated in **Figure 4-1**.
- CCR removal areas were assumed to be graded following placement of soil backfill based on the design drawings provided in the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, 2025).
- CCR consolidation/removal areas were assumed to be graded and include proper storm water controls to remove excess water from the surface using the design drawings provided (HDR, 2025).
- The CIP scenario includes the placement of a stormwater pond within the removal area. It includes excavating nearly 3.6 million cubic yards of CCR and placing it in consolidated CCR footprints at an elevation greater than 12 feet above the uppermost aquifer (UA) and above the estimated post-closure water table and construction of a cover system over the remaining CCR. The outflow elevation of this stormwater pond is 506 feet, which will discharge into Newton Lake adjacent to the PAP. This is represented as a drain in the model whose elevation is equal to the stormwater pond outflow elevation.
- All saturated CCR (constant concentration cells) in the transport calibration model were removed instantaneously in all CCR removal areas for all prediction models.
- Local fill materials applied to the prediction models have similar hydraulic properties as the UD materials used in the transport calibration models. However, the local fill materials were assumed to have reduced vertical anisotropy ratios, approaching isotropic, due to reworking of the material as it is placed as backfill (Kh/Kv decreased from measured values of 100 to 1 for reworked material).

6.2 HELP Model Setup and Results

HELP (Version 4.0; Tolaymat and Krause, 2020) was used to estimate percolation through the PAP in areas of CCR removal with soil backfill, and areas of CCR consolidation with final cover system. HELP input and output files are included electronically and attached to this report.

HELP input data and results are provided in **Table 6-1**. All scenarios were modeled for a period of 30 years. Climatic inputs were synthetically generated using default equations developed for Terra Haute, Indiana (the closest weather station included in the HELP database). Precipitation, temperature, and solar radiation was simulated based on the latitude of the PAP. Thickness of soil backfill and soil runoff input parameters were developed for the ash fill removal scenarios using data provided the *Primary Ash Pond Final Closure Plan Revision 1* (HDR, 2025).

HELP model results (**Table 6-1**) indicated 4.38 and 3.75 inches of percolation per year for the PAP CCR removal and soil backfill area in the CBR and CIP scenarios respectively. Percolation of 0.04 and 0.071 inches per year was modeled through the west, and the east/northeast PAP CCR and final cover systems respectively for the CIP scenario. HELP model simulations were also completed to estimate the percolation for the proposed closure of LF2. Model results indicated 0.000003 inches of percolation per year for this area. The differences in HELP model runs for each area included the following parameters: area, soil backfill thickness, slopes, and soil runoff slope length; all other HELP model input parameters were the same for each simulated area.

HELP input data and results are provided electronically in **Appendix B** and summarized in **Appendix D.**

HELP model simulations were completed to demonstrate that the proposed alternate final protective layer will have a lower infiltration rate than the default 35 I.A.C. 845.750(c)(2) soil final cover system as described in the Update to 2022 Proposed Final Cover Layer Equivalency Demonstration (Ramboll 2025b) which is an appendix to the Final Closure Plan to which this report is also attached. Simulation inputs and output results used in the equivalency demonstration are presented in **Appendix D**.

6.3 Simulation of Closure Scenarios

The calibrated model was used to evaluate the effectiveness of the two closure scenarios by adding constant head cells within the PAP, decreasing recharge to simulate removal of liquids within the ash fill prior to removal, and changing recharge rates to simulate ash fill removal areas at the PAP. Removal of source inputs from the ash removal areas was simulated by reducing the sulfate concentrations associated with recharge in the areas to 0 mg/L. Constant concentration cells that represent areas with potentially saturated CCR were also removed from the ash removal areas.

Each prediction scenario was simulated as a continuation of the PAP dewatering simulation which followed the transient calibrated model. The prediction model input values are summarized in **Table 6-2,** and the modifications to the recharge zones and drain placement for the CIP scenario are illustrated in **Figure 6-1**. **Figure 6-2** illustrates the CCR removal area for the CBR at the PAP. The two closure scenarios are discussed in this report based on predicted changes in sulfate concentrations as described below.

6.3.1 Closure-in-Place Model Results

In the CIP scenario, the predicted concentrations in the UD/PMP start to decline once the closure actions are implemented within the prediction model. The reduced recharge rate in the northern area of the PAP leads to an increasing number of saturated ash cells (constant concentration cells) becoming inactive. These inactive cells are no longer contributing sulfate source concentration to the model domain. Sulfate concentration continues to be introduced in the CIP consolidation area via recharge, although only at a low rate. In addition, as a result of removal of liquids and low recharge rate, downward percolation of solute mass from the PAP is reduced.

As previously discussed, the calibrated model over predicts sulfate concentrations in monitoring wells APW02, APW04, and APW12, which are screened in the UD/PMP. The predictive model indicates that these wells will reach the GWPS (400 mg/L) in 21 years, 34 years, and 5 years respectively, after the corrective measures are in place. All UD/PMP groundwater monitoring wells are below the GWPS within 34 years (**Figure 6-3**). Because the model overpredicts the calibrated concentrations at these wells, the simulated times to reach the GWPS will be conservative and may reach the GWPS earlier than simulated. The predicted footprint of the sulfate plume within the UD/PMP (Layer 3) shown in **Figure 6-3** is considerably reduced from that at the end of the transient model simulation (**Figure 5-30**).

The predicted concentrations in UA groundwater monitoring wells increase for various periods of time after corrective measures are implemented (**Figure 6-4**). However, only APW10 exceeds the GWPS following closure. The predicted concentration in APW10 rises for approximately 10

years after closure is completed, after which it declines such that the concentrations fall below the GWPS after 28.5 years.

Most of the UA wells show a delayed response to the implementation of closure, with the concentrations continuing to rise for up to 200 years in the case of APW17 while remaining below the GWPS. This delay can be attributed to the thick layer of UCU materials present between the UA and the CCR. Due to its low vertical hydraulic conductivity (0.0001 ft/d), sulfate will very slowly percolate through the UCU into the UA. The reduced recharge rate in the CIP scenario further reduces the vertical gradient across this unit, thereby slowing the movement of the sulfate within it. This results in the slow rise and fall of sulfate in many of the UA wells.

The predicted footprint of the sulfate plume within the UA (Layer 6) is shown in **Figure 6-4.** Only a small area to the east of the pond (in close proximity to APW10) shows sulfate concentrations above the GWPS.

Evaluations of post-construction water flux through the consolidated and covered Fill Unit (CCR) were completed using data obtained from the Scenario 1 (CIP) prediction model when simulated post-construction heads in the groundwater monitoring wells are predicted to stabilize (once heads stabilized in the model, the post-construction movement of water in and out of the Fill Unit [CCR] were compared to pre-construction conditions). The pre-construction (calibration model) and post-construction Scenario 1 (CIP) prediction model simulated water flux values are summarized in **Appendix E** and discussed below. Data export files used for flux evaluations are found along with model files in **Appendix B**.

Scenario 1 (CIP) was predicted to reduce total flux in and out of the Fill Unit (CCR) by approximately 99.3% and 99.6% respectively, when simulated post-construction heads in the groundwater monitoring wells are predicted to stabilize (approximate hydraulic steady state) as illustrated in **Figure 6-5**. **Figure 6-6** is a plot showing the changes in flux reduction (shown as negative percentage) over time starting from implementation of Scenario 1 (CIP) through approximate hydraulic steady state conditions. Both flux in and flux out are reduced greater than 90% after one year of closure. Following implementation of Scenario 1 (CIP), influx into the CCR unit decreases rapidly as illustrated in **Figure 6-6**. Concurrently, outflux from the CCR unit behaves similarly, decreasing rapidly and stabilizing 6 years post-construction, after which a reduction of outflux is maintained as heads approach hydraulic stabilization (**Figure 6-6**).

6.3.2 Closure-by-Removal Model Results

In the CBR scenario, predicted concentrations in the UD/PMP start to decline once the closure actions are implemented within the prediction model. These declines are due to removal of the CCR and a small reduction in recharge within the PAP. Predicted sulfate concentrations for APW02, APW03, APW04, APW05S, and APW12 are below the GWPS within 14 years (**Figure 6-3**).

As previously discussed, the model over predicts sulfate concentrations in monitoring wells APW02, APW04, and APW12, which are screened in the UD/PMP. The predictive model indicates that these wells will reach the GWPS 14 years, 10 years, and 13 years respectively, after closure. Because the model overpredicts the calibrated concentrations at these wells, the simulated times to reach the GWPS will be conservative and may reach the GWPS earlier than simulated.

Similar to the CIP scenario, the predicted footprint of the sulfate plume for the CBR within the UD/PMP (Layer 3) shown in **Figure 6-3** is considerately reduced from that of the transient model simulation (**Figure 5-30**). In comparison to the CIP scenario, the CBR simulation has a smaller plume at both the eastern boundary and western boundary of the PAP.

The simulated sulfate concentrations in the UA wells display a similar lagged response to closure as observed in the CIP scenario. Only APW10 exceeds the GWPS following closure. The predicted concentrations in APW10 continue to rise approximately 9 years after closure is completed, after which it declines such the concentrations fall below the GWPS after 16 years.

Like the CIP scenario, most of the UA wells show a delayed response to the implementation of closure, the concentrations continue to rise for up to 50 years in the case of APW18 while remaining below the GWPS.

The predicted footprint of the sulfate plume within the UA (Layer 6) is shown in **Figure 6-4**. Only a small area to the east of the pond (in close proximity to APW10) shows sulfate concentrations above the GWPS and is not significantly different from the CIP simulated plume footprint.

6.3.3 Sulfate Composite Plume for CIP and CBR

The maximum footprint of the plume, based on the simulated sulfate concentrations in all model layers 20 years after corrective measures, is shown in **Figure 6-7**. The footprint of the plume includes the sulfate concentrations retained within the UCU and is therefore greater in area than those plumes in either the UD/PMP or UA. As mentioned above, the sulfate within the thick UCU will slowly percolate through the unit, the rate of which is governed by the hydraulic gradient across the unit. **Figure 6-8** shows the maximum plume extent after 100 years for both the CIP and CBR scenarios. The reduced recharge rate in the CIP scenario leads to a larger plume for the CIP scenario than for the CBR scenario.

The maximum plume footprint in both the CIP and CBR scenarios continues to reduce through time and remains within the property boundaries.

7. CONCLUSIONS

This GMR has been prepared to evaluate how proposed CIP and CBR scenarios will achieve compliance with the applicable groundwater standards at the NPP. The MODFLOW and MT3DMS models used in the previous GMR were used to evaluate two scenarios using information provided in the *Primary Ash Pond Final Closure Plan* Revision 1 (HDR, 2025):

- Scenario 1: CIP (CCR consolidation into eastern and western footprints with cover system construction)
- Scenario 2: CBR (CCR is removed)

The original CIP scenario of CCR consolidation into a single northern footprint was replaced with the current consolidation eastern and western footprints (Scenario 1 above). No changes were made to the original CBR scenario.

Scenario 1 (CIP) is predicted to reduce total flux in and out of the Fill Unit (CCR) by greater than 99%, when simulated post-construction heads in the groundwater monitoring wells are predicted to stabilize. Reduction of post-closure flux of water has improved from 94% in the original closure plan to greater than 99% in the revised plan.

Predictive simulations of pond closure indicate simulated groundwater concentrations in the monitoring wells within the two transport zones, namely the UD/PMP and UA, will achieve the GWPS in 34 years and 14 years for the CIP and CBR closure scenarios, respectively. The model predicted twenty-year time difference when GWPSs are achieved for CIP (34 years post-closure) and CBR (14 years post-closure) is not significant because the estimated duration of construction activities indicates that CBR will take longer to implement than CIP (3.2-4.3 years for CIP compared to 7.8-9.2 years for CBR-Onsite and 22 years for CBR-Offsite; Section 2.1 of the Closure Alternative Analysis [Gradient, 2022] and confirmed in the Updated Closure Alternatives Analysis [Gradient, 2025]).

The prediction simulations indicate that although the groundwater wells reach the GWPS, sulfate remains within the model beyond 100 years in both CIP and CBR scenarios. This is due to the sulfate mass retained within the thick UCU which underlies the PAP. The low vertical hydraulic conductivity of this thick unit leads to low flow rates through the unit which will require time to release the sulfate mass. However, in both the CIP and CBR scenarios, the plume footprint continues to recede with time and remains within the property boundaries indicating these closure options are equally protective.

Results of groundwater flow and transport modeling conservatively estimate that groundwater concentrations will attain the GWPS for all constituents within 34 years of closure implementation for either CIP and CBR. Within the property boundary, residual sulfate will be present within the clay confining unit above the GWPS due to the slow release of sulfate from the UCU.

Notes:
[1] Sensitivity Explanation:
Negligible - SSR changed by less than 1%
Low - SSR change between 1% and 10%
Moderate - SSR change between 10% and 50%
Moderately High - SSR change between 50% and 100%
High - SSR change greater than 100%
SSR = sum of squared residuals
- - - = not tested
CCR = coal combustion residuals
cm/s = centimeters per second
ft/d = feet per day
ft^2/day = feet squared per day
in/yr = inches per year
Kh/Kv = anisotropy ratio
NA = not applicable
PAP = Primary Ash Pond

Hydrostratigraphic Unit
UD = upper drift
LCU = lower confining unit
UA = uppermost aquifer
UCU = upper confining unit
PMP = potential migration pathway

		S*0.1 Sy*0.5[2]		S*10 Sy*2[2]		Porosity-0.05		Porosity+0.05		Disp zone 11*0.5		Disp zone 11*1.5	

Notes:
[1] Sensitivity Explanation:
Negligible = concentration changed by less than 1%
Low = concentration change between 1% and 10%
Moderate = concentration change between 10% and 50%
Moderately High = concentration change between 50% and 100%
High = concentration change greater than 100%
[2] sensitivity test used steady state flow and transient transport
ID = identification
mg/L = milligrams per liter
S = storativity
Sy = specific yield
Disp = dispersivity

APPENDIX A
EVALUATION OF POTENTIAL GWPS EXCEEDANCES

TECHNICAL MEMORANDUM

DATE	April 15, 2022	21454831
TO	David Mitchell, Stu Cravens, Vic Modeer Illinois Power Generating Company	
CC	Brian Hennings - Ramboll	
FROM	Roberta Russell, Jeffrey Ingram, Pat Behling - Golder	**EMAIL jingram@golder.com**

EVALUATION OF POTENTIAL GWPS EXCEEDANCES, PRIMARY ASH POND, NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION

Illinois Power Generating Company (IPGC) currently operates the Newton Power Plant (NPP or Site) located in Jasper County, Illinois. The Primary Ash Pond (PAP, Illinois Environmental Protection Agency [IEPA] ID No. W0798070001-01) is a surface impoundment used to manage coal combustion residuals (CCRs) at the NPP. The PAP is regulated under Part 845 *"Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments"* (State CCR Rule or Part 845) which was promulgated by the Illinois Pollution Control Board (IPCB) on April 21, 2021.

IPGC is currently preparing a Construction Permit application for the PAP as required under Section 845.220 which requires groundwater modelling be completed for the known potential exceedances of groundwater protection standards (GWPS) as outlined in the Operating Permit application (Burns and McDonnell 2021). In October 2021, Ramboll Americas Engineering Solutions, Inc. (Ramboll) identified potential GWPS exceedances for pH in certain monitoring wells in the vicinity of the PAP (Ramboll 2021a). This Technical Memorandum was developed to further evaluate these potential GWPS exceedances.

1.1 Site Setting

The NPP is located in Jasper County Illinois, approximately 20 miles southeast of Effingham and 7 miles southwest of Newton, in Section 26 and 25, Township 6 North, Range 8 East. The NPP has one CCR surface impoundment (the PAP) with a surface area of 404 acres and a non-CCR Secondary Pond with a surface area of 9.3 acres. The PAP currently receives bottom ash, fly ash, and low-volume wastewater from the plant's two coal-fired boilers.

The NPP is situated in a predominantly agricultural area with fields located on the north, west and southern boarders of the property. The eastern border of the property is the Prairie Ridge State Natural Area. The PAP is adjacent to Newton Lake on the southern and eastern sides, with the NPP generating station located to the north of the PAP, and the site's Utility Waste Landfills located to the west.

Six hydrogeologic units are present at the NPP. They are described as follows in the Hydrogeologic Site Characterization Report (Ramboll 2021b), in downward order:

- **CCR:** CCR, consisting mostly of bottom and fly ash. CCR is present from the surface (approximately 545 to 555 feet above mean sea level (ft MSL) down to approximately 475 feet msl at its deepest portions.
- **Upper Drift (UD) / Potential Migration Pathway (PMP):** The UD consists of low-permeability silts and clays of the Peoria Silt and Sangamon Soil units. In some areas, discontinuous lenses of the sandier Hagarstown Member are also present, making up the PMP.
- **Upper Confining Unit (UCU):** the UCU comprises a thick sequence of low-permeability clays and silts of the Vandalia Till Unit. This unit is laterally continuous and is present from the base of the PAP down to the top of the uppermost aquifer.
- **Uppermost Aquifer (UA):** the UA comprises the Mulberry Grove Formation and generally consists of fine to coarse, poorly- to well-graded sands, with occasional clayey sand layers and gravels.
- **Lower Confining Unit (LCU):** This unit consists of the Smithboro Till Member and is generally made up of compact glacial till consisting of low-permeability silty clays and clayey silts with trace sand and gravel.
- **Bedrock Confining Unit (BCU):** Bedrock below the unconsolidated deposits, consisting of shale of the Mattoon Formation.

Groundwater elevations within the PAP are high when compared to the surrounding aquifer, creating a downward gradient between the PAP and the surrounding aquifer. Below the PAP, groundwater migrates downward and laterally through the UD and UCU into the UA. Additionally, as displayed in **Figure 1**, groundwater in the UA flows from the north to the southeast in the eastern portion of the pond and to the south/southwest in the western portion of the pond (Ramboll 2021a).

2.0 POTENTIAL GWPS EXCEEDANCES AND MONITORING WELL DETAILS

As required by Section 845.230 (d)(2)(M), an evaluation of the history of potential GWPS exceedances was completed for the Operating Permit application (Burns and McDonnell 2021; Ramboll 2021b). Data collected since 2015 from the PAP monitoring well network were evaluated using statistical methods described in the Statistical Analysis Plan included in the Operating Permit application (Appendix I, Ramboll 2021c). The following monitoring wells and potential exceedances of the GWPSs are evaluated in this Technical Memorandum:

- **pH at APW04:** For pH, a lower confidence limit (LCL) of 6.1 (in Standard Units; SU) was calculated below the lower GWPS of 6.4. APW04 is located to the east/southeast of the PAP, downgradient of the PAP based on typical flow directions within the UD and UCU. The well is screened in sandy clays of the UD (PMP) from 7.7 to 17.7 FT BGS (513.75 to 503.75 FT MSL).
- **pH at APW12:** For pH, a lower confidence limit (LCL) of 6.2 was calculated below the lower GWPS of 6.4. APW12 is located to the east/northeast of the PAP, typically upgradient of the general groundwater flow direction within the UD and PMP. The well is screened in a mixture of silty clays and sands of the UD (PMP) from 20.0 to 30.0 FT BGS (523.33 to 513.33 FT MSL).

3.0 EVIDENCE THAT POTENTIAL GWPS EXCEEDANCES ARE NOT RELATED TO THE PAP

Groundwater data for monitoring wells that exhibited potential pH GWPS exceedances, background monitoring wells and porewater samples from the PAP were evaluated. The review of these data indicates that the GWPS exceedances are not related to the PAP, as described in the following line of evidence.

- **The pH of CCR porewater is significantly higher than the pH in monitoring wells APW12 and APW04 and the pH ranges recorded in the PMP are likely naturally occurring.**

The pH of porewater within the PAP ranges from approximately 8.6 to 12.2 with an average of 10.7, while pH in all PMP wells (APW02, APW03, APW04, APW5S, APW12) ranges from 6.0 to 7.2, with an average of 6.7 (Table 1). The pH of groundwater in background wells within the UA ranges from 6.4 to 7.8. Due to the high pH values within the PAP, it would be expected that any releases from the PAP would increase the pH in downgradient wells. However, as demonstrated in **Table** 1, downgradient wells within the PMP report pH values significantly lower than in the PAP.

	Background Wells	Upper Drift Wells	PAP Porewater
pH Average	7.5	6.7	10.7
pH Min	6.4	6.0	8.6
pH Max	7.8	7.2	12.4

Table 1. Summary of average, minimum and maximum pH values (in SU) in background wells (APW05, APW06), UD wells (APW02, APW03, APW04, APW05S and APW12) and the PAP.

In addition, pH is consistently slightly lower in all PMP wells compared to background wells (Tables 1 and 2). The average pH values across the PMP wells are similar, i.e. within 0.5 SU of one another. Given the consistency of average pH values across the PMP, it is likely that the slightly lower pH is naturally occurring in the PMP.

Sample Date	APW05	APW06	APW02	APW03	APW04	APW05S	APW12
Well Formation	UA	UA	UD/PMP	UD/PMP	UD/PMP	UD/PMP	UD/PMP
2/17/2021	7.20	6.40	6.60	6.70	6.50	6.60	6.20
3/10/2021	7.70	7.70	7.00	7.20	6.90	7.00	6.50
3/30/2021	7.20	7.10	6.60	6.30	6.10	--	6.00
4/28/2021	7.49	7.69	6.68	7.00	6.86	6.84	6.40
5/25/2021	7.54	7.71	6.67	7.05	6.90	6.86	6.54
6/17/2021	7.73	7.69	6.62	6.98	6.81	6.82	6.45
6/30/2021	7.55	7.61	6.58	7.03	6.80	6.73	6.29
7/15/2021	7.78	7.49	6.55	6.93	6.76	6.77	6.54
Average	**7.52**	**7.42**	**6.66**	**6.90**	**6.70**	**6.80**	**6.37**

Table 2. pH data (in SU) for 2021 sampling events for background wells (APW05, APW06) and PMP wells (APW02, APW03, APW04, APW05S, APW12).

Therefore, the CCR unit is not the cause of the pH values statistically below the lower pH GWPS at APW12 and APW04.

4.0 CLOSING

Golder appreciates the opportunity to serve as your consultant on this project. If you have any questions concerning this Technical Memorandum or need additional information, please contact the undersigned.

EVALUATION OF PARTITION COEFFICIENT RESULTS, PRIMARY ASH POND (CCR UNIT 501), NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION

Illinois Power Generating Company (IPGC) operates the Newton Power Plant (NPP) located in Jasper County, Illinois. The Primary Ash Pond (PAP or Site), Illinois Environmental Protection Agency [IEPA] ID No. W0798070001-01 is a 404-acre unlined surface impoundment used to manage coal combustion residuals (CCRs) at the NPP. The PAP is regulated under Part 845 *"Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments"* (State CCR Rule or Part 845) which was promulgated by the Illinois Pollution Control Board (IPCB) on April 21, 2021. WSP Golder (Golder) is assisting IPGC with Part 845 compliance at the Site.

IPGC is currently preparing a Construction Permit application for the PAP as required under Section 845.220. As a part of the Construction Permit application, groundwater modeling is being completed for known potential exceedances of groundwater protection standards (GWPS) as outlined in the Operating Permit application for the PAP (Burns and McDonnell 2021). In the Operating Permit (October 2021), Ramboll Americas Engineering Solutions, Inc. (Ramboll) identified potential GWPS exceedances for several compounds potentially associated with the PAP, including lithium and sulfate. Batch adsorption testing was conducted to generate site-specific partition coefficient results for these parameters for use in the groundwater models. Site-specific partition coefficients were also developed for boron for its use in groundwater modeling. This Technical Memorandum summarizes the results of the batch adsorption testing.

2.0 OVERVIEW

In August 2021, Golder conducted a field investigation at the PAP which included the completion of seven (7) soil/rock borings ranging in depth from 15 to 90 feet below ground surface (ft bgs; Golder 2021). As a part of that investigation, soil and groundwater samples were submitted to SiREM laboratories (Guelph, ON) for batch solid/liquid partitioning testing. A summary of the soil samples used for the batch testing is provided in Table 1.

Table 1: Batch Attenuation Testing Data Summary

Groundwater Sample ID	Soil Sample ID	Soil: Water Ratio
APW-04	N-SB-05 (60.0-67.1 ft bgs)	2:1
		1:1
		1:5
		1:10
		1:20
APW-14	N-SB-04 (12.0-18.0 ft bgs)	2:1
		1:1
		1:5
		1:10
		1:20

Notes:

1) Ft bgs – Feet below ground surface

Site-specific partitioning coefficients were determined for constituents of interest (COIs) lithium and sulfate, identified based on statistical evaluation of potential groundwater exceedances calculated at the Site (Burns and McDonnell 2021). Site-specific partitioning coefficients were also determined for boron for its potential use in groundwater modeling, despite not being detected at statistically significant levels above the site GWPS. Two groundwater samples (APW-04 and APW-14) and two soil samples (N-SB-05 60.0-67.1 ft bgs and N-SB-04 12.0-18.0 ft bgs) were used for batch attenuation testing at various ratios (Table 1). For each treatment, 0.1 L of groundwater was brought in contact with an amount of soil (0.004 to 0.2 kg, dependent on the ratio) over a seven-day period. Each contact water/soil microcosm was amended (spiked) with meta-arsenite, boric acid, lithium chloride, and sodium sulfate to a target concentration of arsenic, boron, lithium, and sulfate, respectively (Table 2). After the seven-day contact period, COI and boron concentrations were analyzed in the contact water. The control samples (i.e., groundwater samples APW-04 and APW-14) were only analyzed at the initiation of testing. The oxidation/reduction potential (redox) and pH were measured for each batch test at the beginning and end of the contact period and in the control samples. Arsenic is not currently a COI at the Site and, therefore, was not evaluated as part of this report. However, arsenic may be revisited in the future, thus meta-arsenite was included as an amendment (Table 2).

Table 2: Microcosm amendment and target concentration for COIs

COI	Groundwater Sample	Amendment	Target Concentration (mg/L)
Arsenic	APW-04	346.80 µL of a 2 g/L As(III) solution	0.2
	APW-14	344.72 µL of a 2 g/L As(III) solution	
Boron	APW-04	11.40 mL of a 10 g/L H_3BO_3 solution	10

	APW-14	11.32 mL of a 10 g/L H_3BO_3 solution	
Lithium	APW-04	3.40 mL of a 1 g/L LiCl solution	0.3
	APW-14	3.39 mL of a 1 g/L LiCl solution	
Sulfate	APW-04	12.20 mL of a 100 g/L Na_2SO_4 solution	774
	APW-14	24.41 mL of a 100 g/L Na_2SO_4 solution	

Notes:

1) g/L – grams per liter
2) mL – milliliter
3) µg/L – micrograms per liter
4) mg/L – milligrams per liter
5) As(III) – arsenite
6) H_3BO_3 – boric acid
7) LiCl – lithium chloride
8) Na_2SO_4 – sodium sulfate

The results of batch attenuation testing (Tables 3 and 4) were used to calculate the following adsorption isotherms for each COI:

- Linear: $q_e = K_D * C_e$
- Langmuir: $C_e/q_e = 1/(K_L * q_m) + C_e/q_m$
- Freundlich: $\log(q_e) = \log(K_F) + (1/n)\log(C_e)$

Where

K_D, K_L, and K_F = the linear, Langmuir, and Freundlich partition coefficients, respectively (in liters per kilogram; L/kg).

q_e = concentration of the adsorbate in soil

C_e = aqueous concentration of the adsorbate

q_m = 1/slope in the linear expression of the isotherm

n = non-linearity constant

3.0 SUMMARY OF RESULTS

Figures that show the linear, Langmuir, and Freundlich isotherms for each COI are provided in Appendix A. The partition coefficient values for APW-04 and APW-14 are presented in Tables 5 and 6, respectively. The results of the batch adsorption testing can be summarized as follows:

- **Boron**: Calculated K_D values for APW-04 and APW-14 were -1.35 and -0.89 L/kg, respectively, K_L values -6.2E+4 and -1.6E+5 L/kg, respectively, and K_F values 57.4 and 68.7 L/kg, respectively. For comparison, in Strenge and Peterson (1989), partition coefficients for boron range from 0.19 to 1.3 L/kg, depending

on pH conditions and the amount of sorbent (i.e. clay, organic matter, and iron and aluminum oxyhydroxide) present.

- **Lithium:** Calculated K_D values for APW-04 and APW-14 were 4.49 and 5.58 L/kg, respectively, K_L values 6.2E+7 and 1.6E+8 L/kg, respectively, and K_F values 135 and 230 L/kg, respectively. In Strenge and Peterson (1989), partition coefficients for lithium range from 0 to 0.8 L/kg, depending on pH conditions and the amount of sorbent present.
- **Sulfate**: Calculated K_D values for APW-04 and APW-14 were 3.58 and -25.6 L/kg, respectively, K_L values -626 and -2,200 L/kg, respectively, and K_F values 4.11 and 2.14E+11 L/kg, respectively. In Strenge and Peterson (1989), partition coefficients for sulfate are 0.0 L/kg, regardless of pH conditions and the amount of sorbent present.
- **pH and Redox**: Generally, after the seven-day contact time, the pH of each contact water was consistent with the pH of the control samples (7.03 and 7.00 for APW-04 and APW-14, respectively), ranging from 7.02 to 7.06 across the batch tests. The average redox values of the control samples after the seven-day contact time were 40 mV and -26 mV for APW-04 and APW-14, respectively. The redox value of contact water ranged from -111 to +40 mV across treatments.

HELP MODEL OUTPUT FILES

HYDROLOGIC EVALUATION OF LANDFILL PERFORMANCE
HELP MODEL VERSION 4.0 BETA (2018)
DEVELOPED BY USEPA NATIONAL RISK MANAGEMENT RESEARCH LABORATORY

Title: Newton AP CBR **Simulated On:** 1/22/2025 12:34

Layer 1

Type 1 - Vertical Percolation Layer (Cover Soil)

Silty Clay

Material Texture Number 43

Thickness	=	60	inches
Porosity	=	0.452	vol/vol
Field Capacity	=	0.411	vol/vol
Wilting Point	=	0.311	vol/vol
Initial Soil Water Content	=	0.4381	vol/vol
Effective Sat. Hyd. Conductivity	=	1.45E-06	cm/sec

Note: Initial moisture content of the layers and snow water were computed as nearly steady-state values by HELP.

General Design and Evaporative Zone Data

SCS Runoff Curve Number	=	88.7	
Fraction of Area Allowing Runoff	=	100	%
Area projected on a horizontal plane	=	413.3	acres
Evaporative Zone Depth	=	18	inches
Initial Water in Evaporative Zone	=	7.651	inches
Upper Limit of Evaporative Storage	=	8.136	inches
Lower Limit of Evaporative Storage	=	5.598	inches
Initial Snow Water	=	1.570044	inches
Initial Water in Layer Materials	=	26.284	inches
Total Initial Water	=	27.854	inches
Total Subsurface Inflow	=	0	inches/year

Note: SCS Runoff Curve Number was calculated by HELP.

Evapotranspiration and Weather Data

Station Latitude	=	38.93	Degrees
Maximum Leaf Area Index	=	4.5	
Start of Growing Season (Julian Date)	=	120	days
End of Growing Season (Julian Date)	=	300	days
Average Wind Speed	=	8	mph
Average 1st Quarter Relative Humidity	=	73	%
Average 2nd Quarter Relative Humidity	=	71	%
Average 3rd Quarter Relative Humidity	=	75	%
Average 4th Quarter Relative Humidity	=	75	%

Note: Evapotranspiration data was obtained for Newton, Illinois

Normal Mean Monthly Precipitation (inches)

Jan/Jul	Feb/Aug	Mar/Sep	Apr/Oct	May/Nov	Jun/Dec
3.464157	2.363177	4.307613	4.875747	5.596821	4.968593
3.874885	3.10377	3.080127	3.602883	4.376843	2.870644

Note: Precipitation was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28

Normal Mean Monthly Temperature (Degrees Fahrenheit)

Jan/Jul	Feb/Aug	Mar/Sep	Apr/Oct	May/Nov	Jun/Dec
39	38.7	47.8	61.1	70.7	80.8
84.9	82.3	72.7	58.1	47.1	38.2

Note: Temperature was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28
Solar radiation was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28

Average Annual Totals Summary

Title: Newton AP CBR
Simulated on: 1/22/2025 12:35

	Average Annual Totals for Years 1 - 30*			
	(inches)	[std dev]	(cubic feet)	(percent)
Precipitation	46.49	[5.78]	##########	100.00
Runoff	12.610	[4.666]	##########	27.13
Evapotranspiration	29.590	[2.377]	##########	63.66
Subprofile1				
Percolation/leakage through Layer 1	4.380870	[1.077458]	6,572,527.9	9.42
Water storage				
Change in water storage	-0.0956	[1.0769]	-143,483.9	-0.21

* Note: Average inches are converted to volume based on the user-specified area.

HYDROLOGIC EVALUATION OF LANDFILL PERFORMANCE
HELP MODEL VERSION 4.0 BETA (2018)
DEVELOPED BY USEPA NATIONAL RISK MANAGEMENT RESEARCH LABORATORY

Title: Newton PAP Removal **Simulated On:** 8/7/2024 14:37

Layer 1

Type 1 - Vertical Percolation Layer (Cover Soil)

Silty Clay

Material Texture Number 43

Thickness	=	216	inches
Porosity	=	0.452	vol/vol
Field Capacity	=	0.411	vol/vol
Wilting Point	=	0.311	vol/vol
Initial Soil Water Content	=	0.4281	vol/vol
Effective Sat. Hyd. Conductivity	=	1.45E-06	cm/sec

Note: Initial moisture content of the layers and snow water were computed as nearly steady-state values by HELP.

General Design and Evaporative Zone Data

SCS Runoff Curve Number	=	90.2	
Fraction of Area Allowing Runoff	=	100	%
Area projected on a horizontal plane	=	181.7	acres
Evaporative Zone Depth	=	18	inches
Initial Water in Evaporative Zone	=	7.652	inches
Upper Limit of Evaporative Storage	=	8.136	inches
Lower Limit of Evaporative Storage	=	5.598	inches
Initial Snow Water	=	1.570044	inches
Initial Water in Layer Materials	=	92.475	inches
Total Initial Water	=	94.045	inches
Total Subsurface Inflow	=	0	inches/year

Note: SCS Runoff Curve Number was calculated by HELP.

Evapotranspiration and Weather Data

Station Latitude	=	38.93	Degrees
Maximum Leaf Area Index	=	4.5	
Start of Growing Season (Julian Date)	=	120	days
End of Growing Season (Julian Date)	=	300	days

Average Wind Speed	=	8 mph
Average 1st Quarter Relative Humidity	=	73 %
Average 2nd Quarter Relative Humidity	=	71 %
Average 3rd Quarter Relative Humidity	=	75 %
Average 4th Quarter Relative Humidity	=	75 %

Note: Evapotranspiration data was obtained for Newton, Illinois

Normal Mean Monthly Precipitation (inches)

Jan/Jul	Feb/Aug	Mar/Sep	Apr/Oct	May/Nov	Jun/Dec

HYDROLOGIC EVALUATION OF LANDFILL PERFORMANCE
HELP MODEL VERSION 4.0 BETA (2018)
DEVELOPED BY USEPA NATIONAL RISK MANAGEMENT RESEARCH LABORATORY

Title: Newton PAP CIP East **Simulated On:** 8/8/2024 15:45

Layer 1

Type 1 - Vertical Percolation Layer (Cover Soil)
SCL - Sandy Clay Loam
Material Texture Number 10

Thickness	=	6	inches
Porosity	=	0.398	vol/vol
Field Capacity	=	0.244	vol/vol
Wilting Point	=	0.136	vol/vol
Initial Soil Water Content	=	0.2476	vol/vol
Effective Sat. Hyd. Conductivity	=	1.20E-04	cm/sec

Layer 2

Type 1 - Vertical Percolation Layer
Sandy Silty Clay - PAP
Material Texture Number 43

Thickness	=	18	inches
Porosity	=	0.4	vol/vol
Field Capacity	=	0.35	vol/vol
Wilting Point	=	0.3	vol/vol
Initial Soil Water Content	=	0.375	vol/vol
Effective Sat. Hyd. Conductivity	=	1.00E-05	cm/sec

Layer 3

Type 2 - Lateral Drainage Layer
Drainage Net (0.5 cm)
Material Texture Number 20

Thickness	=	0.2	inches
Porosity	=	0.85	vol/vol
Field Capacity	=	0.01	vol/vol
Wilting Point	=	0.005	vol/vol
Initial Soil Water Content	=	0.1782	vol/vol
Effective Sat. Hyd. Conductivity	=	1.00E+01	cm/sec
Slope	=	2	%
Drainage Length	=	2250	ft

Layer 4

Type 4 - Flexible Membrane Liner
LDPE Membrane
Material Texture Number 36

Thickness	=	0.04	inches
Effective Sat. Hyd. Conductivity	=	4.00E-13	cm/sec
FML Pinhole Density	=	1	Holes/Acre
FML Installation Defects	=	1	Holes/Acre
FML Placement Quality	=	3	Good

Layer 5

Type 1 - Vertical Percolation Layer (Waste)
High-Density Electric Plant Coal Fly Ash
Material Texture Number 30

Thickness	=	168	inches
Porosity	=	0.541	vol/vol
Field Capacity	=	0.187	vol/vol
Wilting Point	=	0.047	vol/vol
Initial Soil Water Content	=	0.1875	vol/vol
Effective Sat. Hyd. Conductivity	=	5.00E-05	cm/sec

Layer 6

Type 3 - Barrier Soil Liner
Silty Clay
Material Texture Number 44

Thickness	=	60	inches
Porosity	=	0.479	vol/vol
Field Capacity	=	0.371	vol/vol
Wilting Point	=	0.251	vol/vol
Initial Soil Water Content	=	0.479	vol/vol
Effective Sat. Hyd. Conductivity	=	1.45E-06	cm/sec

Note: Initial moisture content of the layers and snow water were computed as nearly steady-state values by HELP.

General Design and Evaporative Zone Data

SCS Runoff Curve Number	=	84.1	
Fraction of Area Allowing Runoff	=	100	%
Area projected on a horizontal plane	=	90.4	acres
Evaporative Zone Depth	=	18	inches
Initial Water in Evaporative Zone	=	5.994	inches
Upper Limit of Evaporative Storage	=	7.188	inches
Lower Limit of Evaporative Storage	=	4.416	inches
Initial Snow Water	=	1.570044	inches

Initial Water in Layer Materials	=	68.507	inches
Total Initial Water	=	70.077	inches
Total Subsurface Inflow	=	0	inches/year

Note: SCS Runoff Curve Number was calculated by HELP.

Evapotranspiration and Weather Data

Station Latitude	=	38.93	Degrees
Maximum Leaf Area Index	=	4.5	
Start of Growing Season (Julian Date)	=	120	days
End of Growing Season (Julian Date)	=	300	days

Average Annual Totals Summary

Title: DEF Earth NEW PAP CIP East

Simulated on: 2/5/2025 14:23

	Average Annual Totals for Years 1 - 30*			
	(inches)	[std dev]	(cubic feet)	(percent)
Precipitation	46.49	[5.78]	##########	100.00
Runoff	12.233	[4.87]	4,014,357.5	26.32
Evapotranspiration	32.240	[2.871]	##########	69.36
Subprofile1				
Percolation/leakage through Layer 3	2.070798	[0.059882]	679,536.6	4.45
Average Head on Top of Layer 3	24.0070	[1.7568]	---	---
Subprofile2				
Percolation/leakage through Layer 5	1.822327	[0.58916]	598,000.2	3.92
Average Head on Top of Layer 5	0.0017	[0.0006]	---	---
Water storage				
Change in water storage	0.1894	[1.0859]	62,153.7	0.41

* Note: Average inches are converted to volume based on the user-specified area.

HYDROLOGIC EVALUATION OF LANDFILL PERFORMANCE
HELP MODEL VERSION 4.0 BETA (2018)
DEVELOPED BY USEPA NATIONAL RISK MANAGEMENT RESEARCH LABORATORY

Title: NEW DEF Earth PAP CIP West **Simulated On:** 2/5/2025 13:56

Layer 1

Type 1 - Vertical Percolation Layer (Cover Soil)

SCL - Sandy Clay Loam

Material Texture Number 10

Thickness	=	6	inches
Porosity	=	0.398	vol/vol
Field Capacity	=	0.244	vol/vol
Wilting Point	=	0.136	vol/vol
Initial Soil Water Content	=	0.3858	vol/vol
Effective Sat. Hyd. Conductivity	=	1.20E-04	cm/sec

Layer 2

Type 1 - Vertical Percolation Layer

Sandy Silty Clay - PAP

Material Texture Number 43

Thickness	=	30	inches
Porosity	=	0.4	vol/vol
Field Capacity	=	0.35	vol/vol
Wilting Point	=	0.3	vol/vol
Initial Soil Water Content	=	0.4	vol/vol
Effective Sat. Hyd. Conductivity	=	1.00E-05	cm/sec

Layer 3

Type 3 - Barrier Soil Liner

Liner Soil (High)

Material Texture Number 16

Thickness	=	36	inches
Porosity	=	0.427	vol/vol
Field Capacity	=	0.418	vol/vol
Wilting Point	=	0.367	vol/vol
Initial Soil Water Content	=	0.427	vol/vol
Effective Sat. Hyd. Conductivity	=	1.00E-07	cm/sec

Layer 4

Type 1 - Vertical Percolation Layer (Waste)

High-Density Electric Plant Coal Fly Ash

Material Texture Number 30

Thickness	=	252	inches
Porosity	=	0.541	vol/vol
Field Capacity	=	0.187	vol/vol
Wilting Point	=	0.047	vol/vol
Initial Soil Water Content	=	0.1948	vol/vol
Effective Sat. Hyd. Conductivity	=	5.00E-05	cm/sec

Layer 5

Type 3 - Barrier Soil Liner

Silty Clay

Material Texture Number 44

Thickness	=	60	inches
Porosity	=	0.479	vol/vol
Field Capacity	=	0.371	vol/vol
Wilting Point	=	0.251	vol/vol
Initial Soil Water Content	=	0.479	vol/vol
Effective Sat. Hyd. Conductivity	=	1.45E-06	cm/sec

Note: Initial moisture content of the layers and snow water were computed as nearly steady-state values by HELP.

General Design and Evaporative Zone Data

SCS Runoff Curve Number	=	84.5	
Fraction of Area Allowing Runoff	=	100	%
Area projected on a horizontal plane	=	141.2	acres
Evaporative Zone Depth	=	18	inches
Initial Water in Evaporative Zone	=	7.115	inches
Upper Limit of Evaporative Storage	=	7.188	inches
Lower Limit of Evaporative Storage	=	4.416	inches
Initial Snow Water	=	1.570044	inches
Initial Water in Layer Materials	=	107.513	inches
Total Initial Water	=	109.083	inches
Total Subsurface Inflow	=	0	inches/year

Note: SCS Runoff Curve Number was calculated by HELP.

Evapotranspiration and Weather Data

Station Latitude	=	38.93	Degrees
Maximum Leaf Area Index	=	4.5	
Start of Growing Season (Julian Date)	=	120	days
End of Growing Season (Julian Date)	=	300	days
Average Wind Speed	=	8	mph
Average 1st Quarter Relative Humidity	=	73	%
Average 2nd Quarter Relative Humidity	=	71	%
Average 3rd Quarter Relative Humidity	=	75	%
Average 4th Quarter Relative Humidity	=	75	%

Note: Evapotranspiration data was obtained for Newton, Illinois

Normal Mean Monthly Precipitation (inches)

Jan/Jul	Feb/Aug	Mar/Sep	Apr/Oct	May/Nov	Jun/Dec
3.464157	2.363177	4.307613	4.875747	5.596821	4.968593
3.874885	3.10377	3.080127	3.602883	4.376843	2.870644

Note: Precipitation was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28

Normal Mean Monthly Temperature (Degrees Fahrenheit)

Jan/Jul	Feb/Aug	Mar/Sep	Apr/Oct	May/Nov	Jun/Dec
39	38.7	47.8	61.1	70.7	80.8
84.9	82.3	72.7	58.1	47.1	38.2

Note: Temperature was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28
Solar radiation was simulated based on HELP V4 weather simulation for:
Lat/Long: 38.93/-88.28

APPENDIX E
FLUX EVALUATION DATA

Appendix E. Flux Evaluation Data
GROUNDWATER MODELING REPORT
NEWTON POWER PLANT
PRIMARY ASH POND
NEWTON, ILLINOIS

Calibration Model

Model	Model Period (years)	HSU	Total Flux In[1] (ft^3/d)	Total Flux In (gpm)
Calibration Model	45	Fill Unit (CCR)	33427.89	173.65
Model	**Model Period (years)**	**HSU**	**Total Flux Out[1] (ft^3/d)**	**Total Flux Out (gpm)**
Calibration Model	45	Fill Unit (CCR)	-33528.40	-174.17

Scenario 1: CIP (CCR removal from the northwest areas of the Ash Pond, consolidation to the northeast, central and southern areas of the Ash Pond, and construction of a cover system over the remaining CCR)

Prediction Model	Years (Post-Construction Period)	HSU	Total Flux In[1] (ft^3/d)	Total Flux In (gpm)	Reduction in Flux In Post Closure[2] (Percentage, %)
CIP	56	Fill Unit (CCR)	223.70	1.16	99.3%
Prediction Model	**Years (Post-Construction Period)**	**HSU**	**Total Flux Out[1] (ft^3/d)**	**Total Flux Out (gpm)**	**Reduction in Flux Out Post Closure[2] (Percentage, %)**
CIP	56	Fill Unit (CCR)	-133.99	-0.70	99.6%

[O: PR 1/22/25; C: KM 3/27/2025]

Notes:
1. Total flux in and out source data provided in flux calculation data files included in Appendix B.
2. Reduction in flux as compared to flux at the end of calibration model (model period of 45 years).
CCR = coal combustion residuals
CIP = Closure In Place
HSU = Hydrostratigraphic Unit
% = percentage
ft^3/d = cubic feet per day
gpm = gallons per minute

APPENDIX C
MATERIAL QUANTITY, LABOR, AND MILEAGE ESTIMATES FOR ALTERNATIVE 2

RAMBOLL

ILLINOIS POWER GENERATING COMPANY - NEWTON POWER PLANT
CORRECTIVE ACTION ALTERNATIVES ANALYSIS SUPPORTING INFORMATION REPORT (CAAA-SIR)
ALTERNATIVE 2 - SOURCE CONTROL WITH GROUNDWATER EXTRACTION TRENCH[1]

ITEM NO.	ENGINEERING, PRE-CONSTRUCTION, AND CONSTRUCTION SUPPORT TASKS	Units	Quantity	Crew	Daily Output	Labor Hours	Equipment Hours	Notes
1	Pre-Design Investigation, Final Groundwater Extraction Trench Design and Bid Support	LS	1	-	-	0	0	Assumes pre-design investigation is needed as part of the Final Groundwater Extraction Trench design.
2	Engineering Support and CQA During Construction	LS	1	Eng	12	3,240	2,700	Assumed labor and equipment hours based on Ramboll project experience.
	ENGINEERING, PRE-CONSTRUCTION, AND CONSTRUCTION SUPPORT ESTIMATED SUBTOTAL					**3,240**	**2700**	
ITEM NO.	**SITE PREPARATION**	**Units**	**Quantity**	**Crew**	**Daily Output**	**Labor Hours**	**Equipment Hours**	**Notes**
3	Mobilization and De-Mobilization	LS	1	-	-	-	-	Assumes mobilization and demobilization.
4	Tree clearing in Extraction Trench Alignment and Laydown Areas	-	-	-	-	181	121	Assumes some tree clearance and fine site preparation work is needed ahead of construction activities.
	Tree Clearing Down to Grade	Acre	2.6	B7	0.7	181	121	311110100200: Clearing and grubbing, medium trees to 12" diameter, cut and chip. Assumes 25 ft of tree clearance along the approximately 4,600 ft of extraction trench.
5	Staging Area & Temporary Roads Preparation	-	-	-	-	422	65	Assumes some work general preparation of temporary access roads along the trench alignment will be needed specific to extraction trench construction.
	Subsurface Stabilization Nonwoven Geotextile	SY	5,000	2 Clab	2500	32	0	313219161550: Geosynthetic soil stabilization, geotextile fabric, non-woven, 120 lb tensile strength includes scarifying and compaction. Assumes 0.5 acre staging area and approximately 3,500 ft of temporary access road.
	Construct Staging Area & Temporary Roads	SY	5,000	B14	615	390	65	015523500100: Temporary, roads, gravel fill, 8" gravel depth, excluding surfacing. Assumes 0.5 acre staging area and approximately 3,500 ft of temporary access road.
6	Construction Soil Erosion & Sediment Controls	-	-	-	-	415	138	Assumes soil erosion and sediment controls will be implemented only during the groundwater extraction trench construction.
	Silt Fence	LF	8,000	B62	650	295	98	312514161000: Synthetic erosion control, silt fence, install and remove, 3' high. Assumes silt fence is installed on downgradient side of the extraction trench alignments (4,600 ft total with one complete replacement).
	Sediment Log, Filter Sock	LF	5,000	A2	1000	120	40	312514160705: Sediment Log, Filter Sock, 9". Assume sediment log is needed along alignment of extraction trench (4,600 LF total) and settling pond perimeter (1,000 LF).
7	Construction Facilities		-	-	-	-	-	Assumes office trailer, storage boxes, and portable toilets are required during the construction phase of the alternative.
	Office Trailer	MO - in use	12	-	-	-	-	015213200350: Office trailer, furnished, no hookups, 32' x 8'. Assume quantity of one (1).
	Storage Trailers	MO - in use	12	-	-	-	-	015213201350: Storage boxes, 40' x 8'. Assume quantity of two (2) boxes onsite.
	Portable Toilet	MO - in use	12	-	-	-	-	015433406410: Toilet, portable chemical. Assume quantity of four (4) units onsite.
8	Electrical Installation	EA	3	R1B	-	720	0	Electrical installation based on Ramboll experience to install two power drops for low-voltage (120V) power for the pneumatic extraction pumps along the extraction trenches, and one for secondary settling pond discharge of water to outfall. For each power drop, consider the distances from existing power sources.
9	Existing Site Utilities Preparation	-	-	-	-	331	159	Assumes abandonment of conflicting section of fire water conveyance line that extends between the Pump House and the Plant. Assumes updated layout will be determined during design phase.
	Abandonment of Conflicting Section of Fire Water Supply Line - Grouting	Days	5	GRT	1	100	50	Assumes 5 days labor to grout approximately 2,000 LF of existing fire water conveyance line based on Ramboll previous project experience.
	Excavate Utility Trench for Replacement Fire Water Supply Line	LF	1,500	B54	860	14	14	312316142750: Utility trench excavating, chain trencher, 40 HP operator riding, 12" wide trench and backfill, 18" deep. Trench installed from pump house area up toward plant to rejoin existing line.
	Install 8" HDPE Replacement Fire Water Supply Line	LF	1,500	B22A	320	188	75	331413350300: Water supply distribution piping, piping HDPE, butt fusion joints, 40' lengths, 8" diameter, SDR 21. Includes labor, materials, and machine for installation and welding of HDPE pipe for fire water supply line.
	Backfill Fire Water Supply Line Trench with Granular Trench Backfill	LCY	250	B10R	100	30	20	312316133060: Backfill trench, F.E. loader, wheel mtd., 1 C.Y. bucket, 200' haul. Backfill with granular trench backfill. Quantity based on trench dimensions 12" wide, 18" deep, 1,500 ft long.
10	Geotechnical Monitoring	LS	--	GM	--	600	0	Assumes installation of inclinometers, survey prisms, and settlement monitoring devices along the east drain trench where the embankment will be modified. Assumes a 4-person crew installs the monitoring system over a period of 3 weeks. Based on Ramboll experience.

11	Extraction Trench Alignment Preparation Work Pad	-	-	-	-	1,022	322	Assumes construction of a 40-ft wide work pad for the full length of the eastern and western trenches. For the eastern trench, excavation of berm material on the upslope side and fill along the downslope side will be required to level off the work area. Once prepared, surface grading and stabilization will be completed along the eastern trench work pad. For the western trench, it is anticipated that only surface grading and stabilization will be required for the work pad.
	Excavation of Berm Material and Stockpiling	CY	10,000	B12D	2080	77	38	312316420300: Excavating, bulk bank measure, hydraulic, crawler mtd., 3 C.Y. cap (300 CY/hr).
	Loading Stockpiled Berm Material	BCY	10,000	B10T	1575	76	51	312323154070: Borrow, common earth, 3 C.Y. bucket, loading and/or spreading, front end loader, wheel-mounted. Assumes stockpiling of upslope material adjacent to work area.
	Hauling Berm Material to Stockpile	LCY	10,000	B34G	986	81	81	312323206130: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 2,000 ft.
	Spreading/Drying Material on Downslope Side of Work Pad	CY	8,000	B10B	1000	96	64	312323170020: Spread dumped material, no compaction, by dozer.
	Compaction of Work Pad	BCY	8,000	B10G	5200	18	12	312323235680: Compaction, 2 passes, 12" lifts, sheepsfoot or wobbly wheel roller.
	Surface Grading	MSF	204	B11L	30	109	54	312216103600: Fine grading, work pad area. Assumes grading along the eastern (2,600 ft) and western trench (2,500 ft) alignments with additional area on each trench end.
	Subsurface Stabilization Nonwoven Geotextile	SY	8,500	2 Clab	2500	54	--	313219161550: Geosynthetic soil stabilization, geotextile fabric, non-woven, 120 lb tensile strength includes scarifying and compaction; assume we need for working pad. At eastern trench, work pad will span 2,600 ft long and 15 ft wide. At western trench, work pad will span 2,500 ft long and 15 ft wide.
	Install Crushed Gravel Work Pad (8" Thick)	SY	8,500	B14	615	663	111	015523500100: Temporary, roads, gravel fill, 8" gravel depth, excluding surfacing. At eastern trench, work pad will span 2,600 ft long and 15 ft wide. At western trench, work pad will span 2,500 ft long and 15 ft wide.
	SITE PREPARATION ESTIMATED SUBTOTAL					**3,692**	**806**	
ITEM NO.	**GROUNDWATER EXTRACTION TRENCH CONSTRUCTION**	**Units**	**Quantity**	**Crew**	**Daily Output**	**Labor Hours**	**Equipment Hours**	**Notes**
12	Materials	-	-	-	-	1,969	1,969	Purchase of sand/granular material for backfilling the extraction trenches.
	Sand / Granular Backfill	CY	14,833	B13D	376	631	631	Sand/granular backfill for extraction trenches. Assumes eastern trench is 2,000 ft and 30 ft deep and western trench is 2,100 ft and 35 ft deep. Assumes both trenches are 3 ft wide. Based on Ramboll experience.
	Haul Material to Site	LCY	14,833	B34C	99	1,199	1,199	312323203104: Cycle hauling(wait, load, travel, unload or dump & reutrn) time per cycle, excavated or borrow, loose cubic yards, 15 min load/wait/unload, 16.5 C.Y. truck, cycle 50 miles, 45 mph, excludes loading equipment.
	Haul Material to Trench Locations	CY	14,833	B34G	850	140	140	312323206170: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 1 mile. Daily output extrapolated down to 10 min wait. Assumes onsite stockpile location approximately 1/2 mile from each trench. Assumes hauling of granular material to trenches.
13	Installation of Groundwater Extraction Trench and Clay Trench Cap	-	-	-	-	1,039	1,036	Installation of groundwater extraction trench using One-Pass technology performed by a specialty contractor and associated clay cap surface completion activities.
	Trench Excavation	LF	4,100	OP	200	1,025	1,025	OP crew determined from crew information provided by specialty contractor. Assumes two trenches totaling 4,100 ft in length with an approximate depth of 35 ft.
	Hauling Berm Stockpiled Clay for Trench Cap	LCY	585	B34G	850	6	6	312323206170: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 1 mile. Daily output extrapolated down to 10 min wait. Assumes onsite stockpile location approximately 1/2 mile from each trench. Assumes hauling of excavated berm material for use as trench cap.
	Spread Lifts for Clay Trench Cap	CY - as excavated	585	B10B	1000	7	5	312323170020: Spread dumped material, no compaction, by dozer. Daily output edited to match excavation based on experience. Assumes use of overexcavated berm material.
	Compaction of Clay Trench Cap	CY - in place	585	B10Y	5200	1	1	312323235060: Compaction; Riding, vibrating roller, 12" lifts, 2 passes. RS Means Crew is B10Y; altered to B10F based on experience.
14	Spoils Management	CY - Loose	14,833	-	-	387	305	Hauling and management of trench excavation spoils to the PAP for placement beneath the final cover system.
	Loading	CY - as excavated	14,833	B14B	5000	36	24	312316435320: Excavating, large volume projects; excavation with truck loading; excavator, 6 C.Y. bucket, 100% fill factor (assume 10% fluff factor from ground to excavated).
	Hauling and Placement at PAP	CY - as excavated	14,833	B34G	850	140	140	312323206170: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 1 mile. Daily output extrapolated down to 10 min wait.
	Spreading Lifts	CY - as excavated	14,833	B10B	1000	178	119	312323170020: Spread dumped material, no compaction, by dozer. Daily output edited to match excavation based on experience.
	Compaction of Material	CY - in place	14,833	B10Y	5200	34	23	312323235060: Compaction; Riding, vibrating roller, 12" lifts, 2 passes. RS Means Crew is B10Y; altered to B10F based on experience.

15	Groundwater Extraction Trench Mechanical Installation	-	-	-	-	1,522	537	Installion of a system to pump and convey extracted groundwater from the trenches to the new settling pond.
	Install Pneumatic Pumps	EA	17	Q1	1.8	151	0	221429132010: Wet-pit-mounted, vertical sump pump, single stage, 25 GPM, 1 HP, 1-1/2" discharge. Assumes one pump per 200 ft of extraction trench.
	Install Equalization Tank	EA	2	B6	1.0	48	16	Installation of equalization tank at each trench and associated site preparation and instrumentation. Assumes 2 days for installation.
	Install Transfer Pumps and Controllers	EA	2	R30	1.0	52	0	Installation of transfer pump and pump controller at each extraction trench to convey water from settling pond to discharge outfall based on Ramboll project experience. Assumes inclusion of housing structure and 2 days for installation.
	Excavate Utility Trench for Lines to Compressors and Extraction Pumps	LF	5,000	B54	860	47	47	312316142750: Utility trench excavating, chain trencher, 40 HP operator riding, 12" wide trench and backfill, 18" deep. Trench installed from power drop/compressor shed to extraction trench to supply compressed air and power to sump pits.
	Install Mechanical Elements and Piping	EA	1	R30	-	390	0	Assumes furnishing all mechanical elements (air compressors, pneumatic extraction pumps, transfer pumps) and associated HDPE housing piping for distribution of power and housing of mechanical elements throughout the extraction trench system. Assumes approximately 15 days of work.
	Excavate Utility Trench for Conveyance to Settling Pond	LF	7,700	B54	860	72	72	312316142750: Utility trench excavating, chain trencher, 40 HP operator riding, 12" wide trench and backfill, 18" deep. Trench installed from groundwater extraction trench to convey extracted water to the settling pond.
	Install 8" HDPE Conveyance Pipe to Settling Pond	LF	7,700	B22A	320	963	385	331413350300: Water supply distribution piping, piping HDPE, butt fusion joints, 40' lengths, 8" diameter, SDR 21. Includes labor, materials, and machine for installation and welding of HDPE pipe for conveying extracted water from trenches to settling pond.
	Backfill Conveyance Line Trench with Granular Trench Backfill	LCY	428	B10R	100	51	34	312316133060: Backfill trench, F.E. loader, wheel mtd., 1 C.Y. bucket, 200' haul. Backfill with granular trench backfill. Quantity based on trench dimensions 12" wide, 18" deep, 7,700 ft long.
16	Construction of Compressor & Mechanical Sheds	-	-	-	-	540	180	Assumes Ramboll experience for construction of housing unit for air compressor sheds.
	Construct Compressor Shed	EA	2	B6	-	540	180	Assumes pre-fabricated mechanical instrumentation shelter, installed primarily by hand with light equipment assistance. Hours are based on Ramboll experience. Two sheds will include extraction equipment (air compressor and transfer pump) and will be located at the trenches.
17	Installation of Settling Pond	-	-	-	-	1,060	372	Quantity based on 1-acre pond, 5 feet deep. Assume all excavated material is reused for berm construction.
	Excavation and Loading of Settling Pond Material	BCY	8,148	B12D	2080	63	31	312316420300: Excavating, bulk bank measure, hydraulic, crawler mtd., 3 C.Y. cap (300 CY/hr).
	Hauling and Placement of Settling Pond Material	LCY	8,148	B34G	986	66	66	312323206130: Hauling; no loading equipment, including hauling, waiting, loading/dumping; 34 C.Y. off-road, 15 min wait/ld./uld., 15 MPH, cycle 2,000 ft. Daily output extrapolated down to 600 ft cycle.
	Spreading/Drying Material in Berm	CY	8,148	B10B	1000	98	65	312323170020: Spread dumped material, no compaction, by dozer. Daily output edited to match excavation based on experience.
	Compaction of Material in Berm	BCY	8,148	B10G	5200	19	13	312323235680: Compaction, 2 passes, 12" lifts, sheepsfoot or wobbly wheel roller.
	Fine Grading of Berm	MSF	8	B11L	30	4	2	312216103600: Fine grading, tops of lagoon banks for compaction. Assumes 10 ft-wide berm around perimeter of 1-acre settling pond.
	Subsurface Stabilization Nonwoven Geotextile	SY	5,000	2 Clab	2500	32	0	313219161550: Geosynthetic soil stabilization, geotextile fabric, non-woven, 120 lb tensile strength includes scarifying and compaction. Assumes 1 acre settling pond.
	Settling Pond Liner	SF	45,000	B63B	1850	778	195	310519531100: Reservoir liners, membrane lining, 40 mil, LLDPE. Assumes 1 acre ft print.
18	Extracted Water Discharge Management	-	-	-	-	263	96	Based on approximate 1,500 ft distance from settling pond to discharge outfall.
	Install Transfer Pump and Controller	EA	1	R30	1	52	0	Installation of transfer pump and pump controller to convey water from settling pond to discharge outfall based on Ramboll project experience. Assumes inclusion of housing structure and 2 days for installation.
	Excavate Utility Trench for Conveyance to Discharge	LF	1,500	B54	860	14	14	312316142750: Utility trench excavating, chain trencher, 40 HP operator riding, 12" wide trench and backfill, 18" deep. Trench installed from settling pond to convey settled water to outfall for discharge.
	Install 8" HDPE Conveyance Pipe to Discharge	LF	1,500	B22A	320	188	75	331413350300: Water supply distribution piping, piping HDPE, butt fusion joints, 40' lengths, 8" diameter, SDR 21. Includes labor, materials, and machine for installation and welding of HDPE pipe for conveying water from settling pond to discharge point.
	Backfill with Granular Trench Backfill	LCY	83	B10R	100	10	7	312316133060: Backfill trench, F.E. loader, wheel mtd., 1 C.Y. bucket, 200' haul. Backfill with granular trench backfill. Quantity based on trench dimensions 12" wide, 18" deep, 1,500 ft long.
	GROUNDWATER EXTRACTION TRENCH CONSTRUCTION					**6,241**	**4,315**	

ITEM NO.	SITE RESTORATION	Units	Quantity	Crew	Daily Output	Labor Hours	Equipment Hours	Notes
19	Site Restoration	-	-	-	-	286	6	Assumes restoration of grade surface following extraction trench installation activities.
	Erosion Control Blanket	SY	29,040	B1	2500	279	0	312514160100: Rolled erosion control mats and blankets, plastic netting stapled, 2" x 1" mesh, 20 mil. Assumes approximately 6 acres of erosion control.
	Lime	MSF	29	B66	700	1	0	329113234250: Soil preparation, structural soil mixing, spread soil conditioners, ground limestone, 1#/S.Y., tractor spreader. Assumes soils possibly being void of nutrients. Quantity assumes approximately 6 acreas of disturbed areas including staging area and temporary roads, as well as adjacent areas.
	Fertilizer	MSF	29	B66	700	1	0	329113234150: Soil preparation, structural soil .mixing, spread soil conditioners, fertilizer, 0.2#/S.Y., tractor spreader. Assumes soils possibly being void of nutrients. Quantity assumes approximately 6 acreas of disturbed areas including staging area and temporary roads, as well as adjacent areas.
	Grassland Mix	MSF	29	B66	52	4	4	329219142300: Seeding athletic fields, seeding fescue, tall, 5.5 lb. per M.S.F., tractor spreader. Quantity assumes approximately 6 acreas of disturbed areas including staging area and temporary roads, as well as adjacent areas.
	Mulch	MSF	29	B65	530	1	1	329113160350: Mulching, Hay, 1" deep, power mulcher, large. Quantity assumes approximately 6 acreas of disturbed areas including staging area and temporary roads, as well as adjacent areas.
	SITE RESTORATION ESTIMATED SUBTOTAL					**286**	**6**	

ITEM NO.	Corrective Action Operation and Maintenance	Units	Quantity	Crew	Daily Output	Labor Hours	Equipment Hours	Notes
Corrective Action Operation and Maintenance								
20	Groundwater Extraction Trench Operation & Maintenance	-	-	-	-	24,000	24,000	Assumes routine monitoring, maintenance, and electrical service charges for the duration of system operation.
	Field Maintenance	Day	1,200	TM	-	24,000	24,000	Assumes monthly monitoring visits and quarterly maintenance on pneumatic pumps and air compressors over 30 years of operation. Each monthly monitoring visit assumes 2 staff for 2 day and each quarterly maintenance event assumes 2 staff for 4 days to check, clean, and service all mechanical parts.
	Electrical Distribution and Service	MO	360	-	-	-	-	Assumes electrical distribution and usage for operating the extraction and transfer pumps.
21	Non-routine System O&M	-	-	-	-	3,600	0	Assumes non-routine tasks including flushing of groundwater conveyance lines and periodic site visits (e.g., alarm responses or equipment troubleshooting).
	Groundwater Conveyance Line Flushing - Vacuum Truck	LF	240,000	VT	-	1,800	900	330130116140: Pipe, internal cleaning and inspection, cleaning, power rodder with header & cutts, 4"-12" diameter. Assumes one 5-day cleaning event of 8,000 LF of 6" HDPE pipe per year for a total of 30 years.
	Non-Routine Site Visits/Alarm Responses	LS	180	OM	-	1,800	0	Assumes 6 non-routine site visits per year over 30 years of operation. Each non-routine event assumes 2 staff for 1 day.
22	Engineering Oversight/Monitoring	LS	30	Eng	-	-	-	Assumes office-based engineering support over 30 years of operation.

NOTES:

1. Alternative 2: Source Control with groundwater extraction trench is estimated to take approximately 33 years to achieve groundwater protection standards (GWPS-35 I.A.C Section 845.600) at all perimeter wells associated with the Primary Ash Pond (PAP) following PAP closure in place (CIP). The operation and maintenace pe
2. RS Means refers to the 2023 online edition of RS Means Commercial New Construction.
3. See crew tab (Alt 2 - Crews) for assumptions regarding crew size, total labor hours and required construction equipment, as needed, for each task.
4. See mileage tab (Alt 2 - Mileage) for assumptions regarding total mileage for tasks outlined in this alternative.

ACRONYMS:

AC = Acre
CIP = closure in place
CY = Cubic Yard
Loose: Material swelled when removed from compacted state
EA = Each
GWPS = groundwater protection standards
LCY = Loose Cubic Yards
LF = Linear Foot
LS = Lump Sum
MSF = square feet divided by 1000
MO = Month
OMM = Operation, Monitoring, Maintenance
PAP = Primary Ash Pond
SF = Square Feet
SY = Square Yard

CONSTRUCTION MILEAGE AND LABOR ESTIMATES
ILLINOIS POWER GENERATING COMPANY - NEWTON POWER PLANT
CORRECTIVE ACTION ALTERNATIVES ANALYSIS SUPPORTING INFORMATION REPORT (CAAA-SIR)
ALTERNATIVE 2 - SOURCE CONTROL WITH GROUNDWATER EXTRACTION TRENCH

Construction Mileage and Labor Estimates - Alternative 2: Groundwater Extraction Trench

Item	Quantity	Assumptions
Labor Total Hours	13,460	Per projected Construction total in cost estimate (does not include contingency)
Duration of Onsite Construction Days	270	Total Days
Average Daily Crew Size	12	Assumes multiple crew sizes and a 10 hour work day Assumes 1 Ramboll personnel daily for construction oversight
Daily Labor Mobilization Miles	226,800	Includes light and medium commercial vehicles Average of 70 miles round trip per day, as proposed in construction permit for PAP Closure
Vehicles Miles Onsite	48,600	Includes light and medium commercial vehicles 15 miles per day, including onsite mileage and local trips No contingency Included
Equipment Mobilization Miles - Unloaded	10,125	Average of 450 miles round trip for equipment hauling (from Chicago, IL) Average 1 load of equipment per working week
Equipment Mobilization Miles - Loaded	10,125	Average of 450 miles round trip for equipment hauling (from Chicago, IL) Average 1 load of equipment per working week
Onsite Haul Truck Miles - Unloaded	703	34 CY Off Road Dump Truck 1 mile round trip per load
Onsite Haul Truck Miles - Loaded	703	34 CY Off Road Dump Truck 1 mile round trip per load
Offsite Haul Truck Miles - Unloaded	31,250	Assumes 20,000 CY delivered in 16 CY loads of fill material (granular and low permeability material) are delivered to the site from a regional supplier located within 50 miles of the site. Assumes truck is returning to the origin location
Offsite Haul Truck Miles - Loaded	31,250	Assumes 20,000 CY delivered in 16 CY loads of fill material (granular and low permeability material) are delivered to the site from a regional supplier located within 50 miles of the site.
Material Delivery Miles - Unloaded	10,800	Misc. construction materials (erosion controls, piping, geotextile) Assumes 200 mile round trip, average 2 trips per working week
Material Delivery Miles - Loaded	10,800	Misc. construction materials (erosion controls, piping, geotextile) Assumes 200 mile round trip, average 2 trips per working week

OMM Mileage and Labor Estimates - Alternative 2: Groundwater Extraction Trench

Item	Quantity	Assumptions
Labor Total Hours	27,600	Per projected OMM total in cost estimate (does not include contingency)
Duration of Onsite OMM Days	1,380	Total Days
Average Daily Crew Size	2	Assumes multiple crew sizes and a 10 hour work day
Daily Labor Mobilization Miles	648,600	Includes mob/demob from Chicago (460 miles round trip) and local daily commute mileage (50 miles per day) for an average of 235 miles round trip per day
Vehicles Miles Onsite	41,400	Includes light and medium commercial vehicles 15 miles per day, including onsite mileage and local trips No contingency Included
Equipment Mobilization Miles - Unloaded	0	Normal work vehicles only for this alternative & phase No heavy equipment to mobilize
Equipment Mobilization Miles - Loaded	0	Normal work vehicles only for this alternative & phase No heavy equipment to mobilize
Onsite Haul Truck Miles - Unloaded	0	No material hauling onsite will occur under this alternative
Onsite Haul Truck Miles - Loaded	0	No material hauling onsite will occur under this alternative
Offsite Haul Truck Miles - Unloaded	0	No material hauling offsite will occur under this alternative
Offsite Haul Truck Miles - Loaded	0	No material hauling offsite will occur under this alternative
Material Delivery Miles - Unloaded	0	No materials will be delivered during OMM
Material Delivery Miles - Loaded	0	No materials will be delivered during OMM

CAGM = Corrective Action Groundwater Monitoring
CY = Cubic yard
OMM = Operation, Maintenance, and Monitoring

1. INTRODUCTION

Ramboll Americas Engineering Solutions, Inc. (Ramboll) has developed this assessment of groundwater corrective measures on behalf of Illinois Power Generating Company (IPGC) to assist in the compliance with the requirements of Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845 Standards for the Disposal of Coal Combustion Residuals in Surface Impoundments. This assessment applies specifically the coal combustion residuals (CCR) unit referred to as the Primary Ash Pond (PAP) at the Newton Power Plant (NPP), also referred to as Vistra identification (ID) number (No.) 501, Illinois Environmental Protection Agency (IEPA) ID No. W0798070001-01, and National Inventory of Dams (NID) No. IL50719. This report addresses content requirements specific to 35 I.A.C. § 845.660 (Assessment of Corrective Measures) for exceedances of lithium, sulfate, and total dissolved solids (TDS) at the PAP.

1.1 Source Control and Residual Plume Management

IPGC intends to initiate significant source control and residual plume management efforts as part of the PAP closure, as documented in the Final Closure Plan and Construction Permit Application that were submitted to IEPA in July of 2022 (IPGC, 2022). The proposed closure exceeds the minimum Closure Performance Standards listed in 35 I.A.C § 845.750. The closure will include removing free liquids in accordance with the performance standard in 35 I.A.C § 845 and maintaining that condition during the closure construction period. The closure will reduce the hydraulic head that can force leachate into subsurface soils and is the mechanism that can drive risk (United States Environmental Protection Agency [USEPA], 2015a, p. 21342):

> *EPA's risk assessment shows that the highest risks are associated with CCR surface impoundments due to the hydraulic head imposed by impounded water. Dewatered CCR surface impoundments will no longer be subjected to hydraulic head so the risk of releases, including the risk that the unit will leach into the groundwater, would be no greater than those from CCR landfills.*

The PAP will be closed using a consolidate-and-cap approach consisting of excavating nearly 2 million cubic yards of CCR and placing it in a consolidated CCR footprint at an elevation greater than 5 feet above the uppermost aquifer (UA). The consolidated CCR will be covered with an alternate geomembrane final cover system having performance that exceeds the 35 I.A.C §845.750(c)(2) minimum final cover requirements. The proposed source control is predicted to reduce water flux into and out of the PAP by 94% and allow the groundwater protection standards (GWPS) to be achieved within approximately 20 years (Ramboll, 2022). These source control activities will serve as the primary groundwater corrective measure at the PAP. The potentially feasible corrective measures presented herein are intended to be supplementary to the primary source control and are intended to serve as management measures to address any residual plumes that remain after completion of source control.

Attachment A includes summary figures from the Construction Permit Application that show the proposed final source control and primary corrective action.

1.2 Adaptive Site Management

Adaptive site management strategies will be employed as an integral part of ongoing corrective action at the PAP. The adaptive site management approach will allow timely incorporation of new

site information over the closure and post-closure life cycle of the PAP to ensure the achievement of the GWPS. The adaptive site management approach is proposed to expedite progress toward meeting the GWPS while acknowledging uncertainties, such as the persistence of current groundwater flow directions and flux quantities and potential related changes in geochemical conditions. A structured decision-making process and explicitly planned iterations between the implemented corrective measures and monitoring results will ensure that remediation is occurring. System performance and the condition of the residual plume will be monitored as the corrective measure(s) selected through the 35 I.A.C. § 845.710 Corrective Action Plan (CAP) process are implemented to supplement the source control measures described above. If the groundwater concentrations do not decrease consistent with the modeling prediction, the adaptive site management approach will facilitate timely modifications or enhancements to the corrective measure(s), as needed in accordance with 35 I.A.C. § 845.680(b). This approach will be employed to provide continuous improvement to the PAP groundwater remediation in response to new site information and/or the performance of the selected corrective measure(s).

The planned adaptive site management strategies are generally consistent with National Research Council, Interstate Technology & Regulatory Council (ITRC) and USEPA methodologies developed to address sites with long remediation times and high levels of uncertainty regarding the remedial actions necessary to achieve final and protective remediation goals (USEPA, 2022). The elements of the proposed adaptive site management strategy at the PAP will be responsive to the changing conditions associated with pond closure and performance of the selected corrective measure(s) and will include the following:

1. Implementing the groundwater corrective measure(s) selected as part of the CAP for the current conditions at the PAP. The selected corrective measures may include a combination of the technologies presented in this Corrective Measures Assessment (CMA).

2. Establishing both the absolute remedial objective and functional (interim) goals to monitor progress toward the remedial objective. Achieving the GWPS for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary is the remedial objective for the PAP. Specific functional goals will be developed as part of the CAP process. The functional goals will be measurable thresholds for future action and may include short-term or technology-specific objectives and triggers. Functional goals may vary for different locations, CCR constituents or other site-specific considerations (ITRC, 2017) and will serve as benchmarks for comparison to ongoing groundwater monitoring at the PAP.

3. Ongoing groundwater monitoring at the PAP will continue throughout the implementation of source control and residual plume management activities. Post-closure monitoring will continue for a period of at least 30 years, in accordance with 35 I.A.C. § 845.780(c). A comprehensive groundwater monitoring plan (GMP) will be developed as part of the CAP process in accordance with 35 I.A.C. § 845.670 and 35 I.A.C. § 845.220(c)(4). The GMP will include the functional goals and proposed action levels.

4. Groundwater monitoring information will be used to guide decisions regarding whether progress toward the remedial goal is advancing as expected and/or whether additional actions may be needed to achieve the remedial objective, in conjunction with IEPA, as required by 35 I.A.C. § 845.680(b).

2. SITE INFORMATION

The NPP is located in Jasper County in the southeastern part of central Illinois, approximately 7 miles southwest of the town of Newton. The PAP is located in Section 26 and the western half of Section 25, Township 6 North, Range 8 East. The PAP is located south of the power plant and situated in a predominantly agricultural area (**Figure 2-1**). The PAP is surrounded by Newton Lake on the west, south, and east (**Figure 2-2**). Beyond the lake is additional agricultural land.

The NPP's sole CCR surface impoundment (SI), the PAP, was constructed in 1977 and has a design capacity of approximately 9,715 acre-feet. The PAP is an unlined CCR SI with a surface area of 404 acres which currently receives bottom ash, fly ash, and low-volume wastewater from the plant's two coal-fired boilers. The PAP is operated per National Pollutant Discharge Elimination System (NPDES) Permit IL0049191, Outfall 001. A construction permit application for the closure of the PAP (*e.g.,* source control) was submitted to IEPA on July 28, 2022 (IPGC, 2022); permit approval is pending at this time.

2.1 Conceptual Site Model

Significant site investigation has been completed at the NPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the PAP has been well characterized and detailed in the Hydrogeologic Site Characterization Report (Ramboll, 2021), which was prepared to comply with the requirements specified in 35 I.A.C. § 845.620 and expands upon the Hydrogeologic Monitoring Plan (Natural Resource Technology, an OBG Company [NRT/OBG], 2017). The conceptual site model (CSM) is presented below.

Quaternary deposits in the Newton area consist mainly of diamictons and outwash deposits that were deposited during Illinoian and Pre-Illinoian glaciations (Lineback, 1979; Willman et al., 1975). The unconsolidated deposits include the following units (beginning at the ground surface):

- **Upper Drift (UD)/ Potential Migration Pathway (PMP):** The upper drift (UD) is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member. The Peoria Silt and Sangamon Soil units are present within the PAP at thicknesses up to approximately 46 feet, as measured in APW15, and range from 3 to 46 feet thick as observed in APW05 and APW10 (Ramboll, 2021). The hydraulic conductivity of this unit, calculated from field hydraulic test data from monitoring wells screened between 8 and 36 feet below ground surface (bgs), was observed to range from 2.4×10^{-6} to 6.1×10^{-5} centimeters per second (cm/s) with a geometric mean of 1.3×10^{-5} cm/s (Rapps Engineering and Applied Science [Rapps], 1997).
  - **Hagarstown Member/PMP**: The Hagarstown Member consists of the discontinuous, sandier deposits of the UD where present and overlies the Vandalia Till. Where present, the sandy deposits of the Hagarstown are generally less than 2 feet thick, with a maximum encountered thickness of approximately 6.9 feet at APW18 (Ramboll, 2021). Results of field hydraulic conductivity tests in wells screened within the Hagarstown PMP (APW05S and APW12) ranged from 6.1×10^{-4} to 1.5×10^{-2} cm/s, with a geometric mean hydraulic conductivity of 3.1×10^{-3} cm/s (Ramboll, 2021).
- **Upper Confining Unit (UCU)**: The UCU consists of a thick, 26 feet thick on average with a maximum observed thickness of 59 feet at APW07, package of the low permeability clay and silt of the Vandalia Till Member. This unit is a laterally continuous layer between the base of

the upper drift and the top of the UA. The hydraulic conductivity of this unit was observed to range from 6.3 x 10^{-9} to 2.1 x 10^{-8} cm/s with a geometric mean of 1.1 x 10^{-8} cm/s (Rapps, 1997).

- **Uppermost Aquifer (UA):** The UA is composed of the Mulberry Grove Member, which has been classified as poorly graded sand, silty sand, clayey sand, and gravel. The top of the UA is highest in elevation in the north and east portions of the unit and slopes downward toward APW15. The top of unit elevations range from approximately 482 feet[1] (APW05 and APW10) to 425 feet (APW15). The average thickness of the Mulberry Grove sands and gravels is approximately 10 feet, with a maximum thickness of 30 feet observed at APW17. Field hydraulic conductivity tests conducted in 2021 at monitoring wells screened in the UA ranged from 2.0 x 10^{-4} to 1.5 x 10^{-1} cm/s with a geometric mean hydraulic conductivity of 6.8 x 10^{-3} cm/s. The highest conductivities are measured in APW15, APW16, and APW17 (Ramboll, 2021).
- **Lower Confining Unit (LCU):** The LCU is comprised of low permeability silt and clay of the Smithboro Till Member and the Banner Formation. The unit was encountered at thicknesses up to 36 feet in APW14), while the average thickness is 32 feet (Ramboll, 2021). The hydraulic conductivity of this unit was observed to be 1.4 x 10^{-7} cm/s (Rapps, 1997).
- **Bedrock Unit:** Shale bedrock of the Pennsylvanian-age Mattoon Formation (Willman et al., 1967) was encountered at the NPP during recent and historical investigations. Based on boring logs, the bedrock surface elevation at the NPP ranges from 408 feet (B141) to 445 feet (APW13) (Ramboll, 2021). Bedrock was not encountered at APW15, which was advanced to approximately 412 feet (Ramboll, 2021). This indicates that APW15, which is screened within the UA from 424 to 419 feet, is located in close proximity to the bedrock surface.

Groundwater flow in the UA is generally from north to south. However, UA wells also display flow converging towards a former surface drainage feature located west of the PAP and an area where the UA is lowest in elevation. Groundwater elevations in the UA vary seasonally, generally less than one foot per year, while across the PAP they range from approximately 490 to 530 feet, although flow directions are generally consistent. Groundwater elevations and contours for the April 24, 2023 monitoring event (Event 1 [E001]) are presented in **Figure 2-3**.

2.2 Groundwater Quality

Groundwater monitoring in accordance with the proposed GMP and sampling methodologies provided in the operating permit application for the PAP began in the second quarter of 2023. The 35 I.A.C § 845 groundwater monitoring system is displayed on **Figure 2-4** and consists of two background monitoring wells screened in the UA, 11 compliance wells screened in the UA, five compliance wells screened in the UD, and two temporary water level only surface water staff gages. The groundwater samples collected from the 18 wells are used to monitor and evaluate groundwater quality and demonstrate compliance with the groundwater quality standards listed in 35 I.A.C. § 845.600(a). The proposed monitoring wells yield groundwater samples that represent the quality of downgradient groundwater at the CCR boundary (as required in 35 I.A.C. § 845.630(a)(2)).

The E001 sampling event was completed on April 28, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), statistically derived values were compared with the GWPSs summarized in

[1] All elevations in this report are referenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

35 I.A.C. § 845.600 to determine exceedances of the GWPS (Ramboll, 2023a). The statistical determinations initiated during E001 identified the following GWPS exceedances at compliance groundwater monitoring wells:

- Lithium in UD/PMP well APW02;
- Sulfate in UD/PMP wells APW02, APW04, APW05S, and in UA well APW10;
- TDS in UD/PMP wells APW02, APW04, APW05S and APW12;
- Chloride in UA well APW15.

Pursuant to 35 I.A.C. § 845.650(e), an alternative source demonstration (ASD) was prepared and submitted to IEPA that presented evidence demonstrating that sources other than the PAP were the cause of the chloride GWPS exceedance listed above (Ramboll, 2023b).

The IEPA did not concur with the ASD due to the following alleged data gaps:

1. Source characterization of the CCR at the PAP must include total solids sampling in accordance with SW846.
2. Hydraulic conductivities from laboratory or in-situ testing must be collected, analyzed, and presented with hydrogeologic characterization of bedrock unit.
3. Characterization to include sample and analysis in accordance with 35 IAC § 845.640 of alternative source must be provided with the ASD.

IPGC submitted written comments and additional information in response to IEPA's request for information and filed a petition asking the Illinois Pollution Control Board (IPCB) to review IEPA's ASD denial. Implementing corrective actions to address naturally occurring compounds in groundwater will not be effective and IPGC believes that it is likely that it will succeed on the merits of the petition for review of the ASD denial. The petition included a motion for a partial stay of the 35 I.A.C. § 845 requirements as they apply to the exceedance of the chloride GWPS at the PAP. The IEPA had no objection to the requested stay, which was granted by IPCB on January 18, 2024. Therefore, the CMA will address identified GWPS exceedances, exclusive of chloride exceedances at APW15, in accordance with 35 I.A.C. § 845.660 and the partial stay. The 35 I.A.C. § 845.650 groundwater monitoring requirements will continue to ensure that there will be timely detection of any additional changes in groundwater quality during the stay. The inclusion of the chloride GWPS exceedance in the CAP process will remain under review pending IPCB's final action on IPGC's appeal of the IEPA ASD denial or until IPCB orders otherwise.

3. CORRECTIVE MEASURES ASSESSMENT METHODOLOGY

This section describes the CMA methodology initiated in response to the identification of exceedances of the GWPSs for 35 I.A.C. § 845.600 constituents at the downgradient waste boundary of the PAP during the E001 groundwater monitoring event (Ramboll, 2023a). The CMA was initiated on November 5, 2023, within 90 days after the detection of exceedance(s) of GWPS. Under 35 I.A.C. § 845, owners and operators of existing CCR SI must initiate the assessment of corrective measures in accordance with 35 I.A.C. § 845.660 if one or more constituents are detected, and confirmed by an immediate resample, to be in exceedance of a GWPS in 35 I.A.C. § 845.600, and the owner or operator has not demonstrated that: a source other than the CCR SI caused the exceedance, or; that the exceedance of the GWPS resulted from error in sampling, analysis, statistical evaluation, natural variation in groundwater quality or a change in the potentiometric surface and groundwater flow direction (an ASD).

The CMA is the first step in developing a long-term CAP to address the GWPS exceedances at CCR SIs. The process provides a systematic, rational method for evaluating potential corrective measures by first identifying potentially viable technologies and assessing them using qualitative information to eliminate from consideration infeasible or otherwise unacceptable remedial technologies (*i.e.,* the 35 I.A.C. § 845.660 CMA). The remaining technologies will be evaluated individually, or assembled into combined alternatives, and further evaluated under the 35 I.A.C. § 845.670 CAP process.

This CMA identified applicable corrective measure technologies and evaluated them for viability, given the site-specific conditions and considerations at the PAP, by addressing the following 35 I.A.C § 845.660 evaluation criteria:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the corrective action plan; and
- Institutional requirements, such as State or local permit requirements or other environmental or public health requirements, that may substantially affect implementation of the corrective action plan.

The evaluation included qualitative and/or semi-quantitative screening of the potential corrective measures (technologies) relative to their general performance, reliability, and ease of implementation characteristics and their potential impacts, timeframes, and institutional requirements to assess the viability of each technology to address the GWPS exceedances at the PAP. This approach provided a reasoned set of corrective measures that could be used, either individually or in combination, to supplement the primary source control measures described in **Section 1.1**. This set of corrective measures will be further evaluated in the Corrective Action Alternatives Analysis (CAAA).

4. DESCRIPTION OF POTENTIAL CORRECTIVE MEASURE TECHNOLOGIES

The potential groundwater corrective measures summarized below are applicable to the PAP and were included in the CMA development and analysis. Site-specific considerations provided in **Section 2** were used to evaluate potential groundwater corrective measures. Each of the corrective measures evaluated may be capable of satisfying the requirements and objectives, listed in **Section 3**, to varying degrees of effectiveness. The corrective measure review process was intended to yield a set of applicable corrective measures that could be used to supplement the primary corrective action, which will be the source control activities described in **Section 1.1** (hybrid consolidate-and-cap approach with a geomembrane final cover system). The source control is expected to reduce downgradient concentrations in the UA to less than the GWPS via naturally occurring physical and chemical processes over an approximately 20-year timeframe. Ongoing monitoring will be an integral part of all corrective measures to verify and document the remedial process. The corrective measures ultimately advanced to the CAAA and selected in the CAP will be used to enhance the effectiveness of the source control and may be used independently or combined into specific remedial alternatives to leverage the advantages of multiple corrective measures to attain GWPSs.

Source control measures will be initiated for the PAP, as described in **Section 1.1**; all of the evaluated additional corrective measure technologies are proposed to be supplemental and complementary to source control activities. The following potential corrective measures, commonly used to mitigate groundwater impacts, were considered as a part of the CMA process:

- Source Control with Groundwater Polishing;
- Source Control with Groundwater Extraction (groundwater pumping wells or collection trenches);
- Source Control with a Cutoff Wall; and
- Source Control with In-Situ Treatment (Permeable Reactive Barrier [PRB] or In-Situ Chemical Treatment).

4.1 Source Control with Groundwater Polishing

Both federal and state regulators have long recognized that natural geochemical processes can be an acceptable component of a remedial action when it can achieve remedial action objectives in a reasonable timeframe. In 1999, the USEPA published a final policy directive (USEPA, 1999) for groundwater remediation and described the process as follows:

- *"The reliance on natural attenuation processes (within the context of a carefully controlled and monitored site cleanup approach) to achieve site-specific remediation objectives within a time frame that is reasonable compared to that offered by other more active methods. The natural attenuation processes that are at work in such a remediation approach include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in-situ processes include biodegradation; dispersion; dilution; sorption; volatilization; radioactive decay; and chemical or biological stabilization, transformation, or destruction of contaminants."*

The USEPA has stated that source control is the most effective means of ensuring the timely attainment of remediation objectives (USEPA, 1999). Natural geochemical processes may be appropriate as a "finishing step" after effective source control implementation (*i.e.*, groundwater polishing), to reduce the residual mass remaining in the groundwater after closure, if there are no risks to receptors and/or the contaminant plume is not expanding. Thus, groundwater polishing would be used in conjunction with the significant planned source control effort at the site, which will consist of a hybrid consolidate-and-cap approach with a final cover system described in **Section 1.1**.

In 2015, USEPA addressed remediation of inorganic compounds in groundwater and noted that the use of natural geochemical processes to address inorganic contaminants: (1) is not intended to constitute a treatment process for inorganic contaminants; (2) when appropriately implemented, can help to restore an aquifer to beneficial uses by immobilizing contaminants onto aquifer solids and providing the primary means for attenuation of contaminants in groundwater; and (3) is not intended to be a "do nothing" response (USEPA, 2015b). Rather, documenting the applicability of natural geochemical processes for groundwater remediation should be thoroughly and adequately supported with site-specific characterization data and analysis (USEPA, 1999; USEPA, 2007; USEPA, 2015b):

Both physical and chemical processes can contribute to the reduction of the small amount of residual mass remaining after closure of the PAP, and the toxicity, mobility, volume, or concentration of contaminants in groundwater. Physical processes applicable to CCR constituents in groundwater include dilution, dispersion, and flushing. Chemical processes applicable to CCR constituents in groundwater include precipitation and coprecipitation (*e.g.,* incorporation into sulfide minerals), sorption (*e.g.,* to iron, manganese, aluminum; to other metal oxides or oxyhydroxides; or to sulfide minerals or organic matter), and ion exchange.

All inorganic compounds are subject to physical processes and under typical environmental conditions, the physical mechanisms most often exert the dominant control on the CCR constituents of interest. Chemical mechanisms are also likely to be active, though not often dominant, such as adsorption, ion exchange, and organic complexation. In combination with source control, these natural controls can provide an effective means to polish residual loading and achieve the GWPS in a reasonable timeframe. Additional data collection and analysis may be required to support the USEPA's evaluation framework (USEPA, 2015b) and obtain regulatory approval.

4.2 Source Control with Groundwater Extraction

Groundwater extraction is one of the most widely used groundwater corrective technologies and has a long history of performance. This corrective measure includes installation of one or more groundwater pumping wells or an extraction trench to control and extract impacted groundwater. Groundwater extraction captures and contains impacted groundwater and can limit plume expansion and/or off-site migration. Construction of a groundwater extraction system typically includes, but is not limited to, the following primary components:

- Designing and constructing a groundwater extraction system consisting of one or more extraction wells or trenches and operating at a rate to allow capture of CCR impacted groundwater within the UA and or the UD/PMP.

- Management of extracted groundwater, which may include modification to the existing NPDES permit.
- Ongoing inspection and maintenance of the groundwater extraction system.

Remediation of inorganics by groundwater extraction can be effective, but systems do not always perform as expected. A combination of factors, including geologic heterogeneities, difficulty in flushing low-permeability zones, and rates of contaminant desorption from aquifer solids can limit effectiveness. Groundwater extraction systems require ongoing operation and maintenance to address issues such as iron bacteria and well fouling and to ensure optimal performance. The extracted groundwater must be managed, either by ex-situ treatment or disposal.

Groundwater extraction may reduce the timeframe to achieve GWPS and limit the off-site migration of constituents that exceed the GWPS. Extraction could be accomplished using a groundwater pumping well system or an extraction trench.

4.3 Source Control with Groundwater Cutoff Wall

Since the late 1970s and early 1980s, vertical cutoff walls have been used to control and/or isolate impacted groundwater. Low-permeability cutoff walls can be used to prevent horizontal off-site migration of potentially impacted groundwater. Cutoff walls act as barriers to lateral transport of impacted groundwater and can isolate soils that have been impacted by CCR to prevent mixing with unimpacted groundwater. Cutoff walls are often used in conjunction with an interior pumping system to establish an inward gradient within the cutoff wall. The gradient imparted by the pumping system maintains an inward flow through the wall, keeping it from acting as a groundwater dam and controlling potential end-around or breakout flow of contaminated groundwater. Constructing the cutoff wall such that it intersects a low-permeability material at its base, referred to as "keying", greatly increases its effectiveness.

A commonly used cutoff wall construction technology is the slurry trench method, which consists of excavating a trench and backfilling it with a soil-bentonite mixture, often created with the excavated soils, or, for deeper walls, a cement-bentonite mixture that is produced at an onsite batch plant. The trench is temporarily supported with bentonite slurry pumped into the trench during excavation (D'Appolonia & Ryan, 1979). Cutoff wall excavation uses conventional hydraulic excavators, hydraulic excavators equipped with specialized booms to extend their reach (*i.e.,* long-stick excavators), clamshells, or more specialized equipment such as hydromills, secant-pile drill rigs, or one-pass machines, depending upon trench depth, material excavated, and type of material that the wall is keyed into.

Cutoff walls are a widely accepted technology for containing impacted groundwater. Combining groundwater polishing with a limited cutoff wall and groundwater extraction in specific areas may provide advantages over independent use of these potential corrective technologies. Cutoff walls can be used in combination with groundwater extraction or as part of a PRB system (as the "funnel" in a funnel-and-gate system; **Section 4.4**).

4.4 Source Control with In-Situ Chemical Treatment

The use of in-situ treatment, either by injection or PRBs is a widely used technology for treating impacted groundwater. However, in-situ treatment techniques for lithium and sulfate are not well established, therefore performance is unknown.

Chemical treatment could consist of injection of reactive materials into the subsurface to treat contaminants at specific, targeted locations. Alternatively, treatment could be accomplished via PRB, where subsurface barriers (*i.e.,* cutoff walls) are placed at locations designed to direct the contaminant plume along a flow path through the reactive media. In either system, the contaminants are transformed or otherwise rendered into environmentally acceptable forms to attain remediation concentration goals downgradient of the barrier (Electric Power Research Institute [EPRI], 2006).

As groundwater passes through the PRB under natural gradients, dissolved constituents in the groundwater react with the reactive media and are transformed or immobilized. A variety of media have been used or proposed for use in PRBs. Zero-valent iron (ZVI) has been shown to effectively immobilize some CCR constituents, including arsenic, chromium, cobalt, molybdenum, selenium, and sulfate. Use of a combination media consisting of ZVI and a boron-selective ion exchange resin to treat boron has been documented in a pilot-scale test (EPRI, 2006).

System configurations include continuous PRBs, in which the reactive media extends across the entire path of the contaminant plume; and funnel-and-gate systems, where low-permeability barriers are installed to control groundwater flow through a permeable gate containing the reactive media. Continuous PRBs intersect the entire contaminant plume and do not materially impact the groundwater flow system. Design may or may not include keying the PRB into a low-permeability unit at depth. Funnel-and-gate systems utilize a system of barriers to groundwater flow (funnels) to direct the contaminant plume through the reactive gate. The barriers, typically some form of cutoff wall, are keyed into a low-permeability unit at depth to prevent short circuiting of the plume. Funnel-and-gate design must consider the residence time to allow chemical reactions to occur. Directing the contaminant plume through the reactive gate can significantly increase the flow velocity, thus reducing residence time.

Design of in-situ treatment systems requires rigorous site investigation to characterize the site hydrogeology and to delineate the contaminant plume. A thorough understanding of the geochemical and redox characteristics of the plume is critical to assess the feasibility of the process and select appropriate reactive media. Laboratory studies, including batch studies and column studies using samples of site groundwater, are needed to determine the effectiveness of the selected reactive media at the site (EPRI, 2006). The main considerations in selecting reactive media are as follows (Gavaskar et al., 1998; cited by EPRI, 2006):

- Reactivity - The media should be of adequate reactivity to immobilize a contaminant within the residence time of the design.
- Hydraulic performance - The media should provide adequate flow through the PRB, meaning a greater particle size than the surrounding aquifer materials. Alternatively, gravel beds have been emplaced in front of barriers to direct flow through the barrier.
- Stability - The media should remain reactive for an amount of time that makes its use economically advantageous over other technologies.
- Environmentally compatible by-products - Any by-products of media reaction should be environmentally acceptable. For example, iron released by zero-valent iron corrosion should not occur at levels exceeding regulatory acceptance levels.
- Availability and price: The media should be easy to obtain in large quantities at a price that does not negate the economic feasibility of using a PRB.

5. ASSESSMENT OF CORRECTIVE MEASURE TECHNOLOGIES

This CMA was initiated to address exceedances of the 35 I.A.C. § 845.600 GWPS for lithium, sulfate, and TDS at the downgradient waste boundary of the PAP identified during the E001 groundwater monitoring event (**Section 2.2**).

5.1 Requirements

The potential groundwater corrective technologies described in the previous section were evaluated relative to the requirements presented in **Section 3** and reiterated below:

- Performance, reliability, ease of implementation and potential impacts of appropriate potential remedies, including safety impacts, cross-media impacts, and control of exposure to any residual contamination;
- Time required to begin and complete the corrective action plan; and
- Institutional requirements, such as State or local permit requirement or other environmental or public health requirements that may substantially affect implementation of the corrective action plan.

Table 5-1 presents the qualitative CMA evaluation for each corrective technology relative to these requirements, as well as their ability to address lithium, sulfate, and TDS GWPS exceedances. The following sections provide a summary of these evaluations and a discussion of the potential groundwater corrective measure technologies that may be viable, either independently or in combination, to address GWPS exceedances. This section also provides a summary of corrective measure technologies that have been retained and advanced for evaluation as part of the CAAA process for selecting the final remedy for the PAP per 35 I.A.C. § 845.670.

5.2 Groundwater Corrective Technology Assessment

Source control, consisting of CCR consolidation and closure-in-place (CIP) with a final cover system, will be the primary groundwater corrective measure for the PAP. Closure is expected to be completed in 2028 and each of the potential groundwater corrective measure technologies would supplement the positive impact of the closure activities. The following sections evaluate groundwater corrective measure technologies that, when combined with site closure, may be viable to address the lithium, sulfate, and TDS GWPS exceedances. Technologies that are not viable for addressing exceedances of GWPS at the PAP will be eliminated from further evaluation and viable technologies will be advanced for further evaluation as part of the CAAA process per 35 I.A.C. § 845.600.

5.2.1 Source Control with Groundwater Polishing

Source control corrective measures (**Section 1.1**) will reduce the mass loading to the groundwater system and the groundwater polishing process could decrease the timeframe for attainment of GWPS in the UA. Groundwater flow and fate and transport modeling incorporating only physical processes indicate that source control would meet GWPS in approximately 20 years. Physical processes are expected to perform well in the UA, as discussed below.

Groundwater polishing by natural geochemical processes is a widely accepted component of groundwater remediation and is routinely approved by the IEPA when paired with source control. The performance of groundwater polishing as a groundwater corrective measure varies based on site-specific conditions and additional data collection may be needed to support the design and achieve regulatory approval. The sandy nature of the UA suggests good performance by physical processes in addressing the sulfate in the UA. The chemical processes in the fine-grained UD require further evaluation.

Naturally occurring geochemical processes are ongoing at the PAP and will continue to affect groundwater constituent concentrations during and after PAP closure. Ongoing monitoring of groundwater conditions is needed to better understand the mechanisms and efficacy of the groundwater polishing process and to confirm the effectiveness over time. Thus, additional groundwater sample collection and analyses would be required to characterize potential mechanisms, as discussed above, and to provide long term monitoring of the remedial progress. Enhancements to the groundwater monitoring system may be required to ensure that groundwater polishing is occurring as predicted by the groundwater and consistent with the adaptive site management approach. The reliability of groundwater polishing as a groundwater corrective measure is high because operation and maintenance requirements are limited. However, the reliability can also vary based on site-specific hydrogeologic and geochemical conditions.

Following characterization and approval of the CAP, monitoring of the groundwater polishing processes and comparison to functional goals established to monitor progress toward the remedial objective could begin prior to, or concurrently with, site closure activities. Installing additional monitoring wells could begin as quickly as within a few months of CAP approval. The time required could be reduced if existing groundwater monitoring well systems could be utilized for monitoring.

No potential safety impacts or exposure to human health or environmental receptors are expected to result from the groundwater polishing processes. Timeframes to achieve GWPS are dependent on site-specific conditions, which require detailed technical analysis which are ongoing and will be evaluated in connection with the CAAA. Selecting groundwater polishing as a corrective measure for the PAP will require approval of the closure and CAP permits by the IEPA.

Monitoring the groundwater polishing to track progress toward achievement of the GWPS, in conjunction with source control at the PAP, would require long-term maintenance and monitoring of the groundwater monitoring system to confirm source control and verify the effectiveness in reducing groundwater concentrations to levels below the GWPS. System design could begin immediately after approval of the CAP permit. Additional investigations to characterize site conditions and installation of the final monitoring system could be performed concurrently with the source control (unit closure) activities, which are currently expected to be completed in 2028.

Groundwater polishing processes will continue before and after source control implementation and may be a viable corrective measure for the sulfate and lithium exceedances at the PAP. Therefore, these processes are being advanced to the CAAA for further evaluation.

5.2.2 Source Control with Groundwater Extraction

Source control will reduce the mass loading to the groundwater system and implementing a groundwater extraction system may reduce the time required to attain the GWPS in the UA.

However, the groundwater impacts already present in the low permeability PMP may limit the reduction in time to attain the GWPS that can be achieved by a groundwater extraction system.

Groundwater extraction is a widely accepted corrective measure with a long track record of performance and reliability. It is routinely approved by the IEPA. For a corrective measure using groundwater extraction to effectively control off-site flow and/or to remove potentially contaminated groundwater, horizontal and vertical capture zone(s) must be created. However, the low permeability PMP would restrict the ability to pump at rates high enough to establish the required capture zone(s) or would require a high density of wells or a trench drainage system. The performance of a groundwater extraction system would be expected to be effective in the high permeability UA (mean hydraulic conductivity of 6.8×10^{-3} cm/s). However, the proximity and influence of Newton Lake to the impacted area of the UA would potentially result in large volumes of extracted groundwater and lake water. Cutoff walls (**Section 4.3**) could also be used in conjunction with a pumping system to control potential groundwater movement from the lake. A groundwater extraction system in the PMP would be limited by its low permeability (mean hydraulic conductivity of 1.3×10^{-5} cm/s); however, a low volume extraction trench in the PMP could be used to enhance groundwater capture from the PMP.

Implementation of a groundwater extraction system presents design challenges due to the proximity to Newton Lake. An extraction system in the UA would have to consider the potential for extracting unimpacted lake water. Construction of an extraction system between the PAP and Newton Lake may be challenging due to the physical site constraints (limited construction area). Extracted groundwater (and potentially lake water) would need to be managed, which may include modification to the existing NPDES permit and treatment prior to discharge, if necessary. Specialized treatment equipment may be required, and ongoing operations and maintenance activities would be necessary.

There could be some impacts associated with constructing and operating a groundwater extraction system, including some limited exposure to extracted groundwater. Additional data collection and analyses would be required to design an extraction system. Construction could be completed within 1 year following completion of a final design. Time of implementation is approximately 3 to 4 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on site-specific conditions. An extraction system may reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling. However, accelerated attainment of the GWPS is expected to be limited by the low permeability of the PMP.

Implementing a groundwater extraction system at the PAP would require IEPA approval of the CAP permit, and discharge of extracted groundwater may require a modification to the NPDES permit, as well as possibly permitting and construction of a new outfall. Depending upon the location of the extraction system an Illinois Department of Natural Resources (IDNR) dam safety modification permit may also be required to construct an extraction system.

Groundwater extraction could be viable corrective measure for the sulfate and lithium exceedances at the PAP. Implementation of groundwater extraction may require combining an extraction system with a cutoff wall to prevent potential inflow of water from Newton Lake. Therefore, groundwater extraction is being advanced to the CAAA for further evaluation.

5.2.3 Source Control with Groundwater Cutoff Wall

Source control will reduce the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. A low permeability cutoff wall could be used in combination with a groundwater extraction system in the UA to reduce the potentially high volumes of extracted groundwater that would be captured by and extraction system between the PAP and Newton Lake. A cutoff wall could reduce the water management and treatment requirements for an extraction system.

Groundwater cutoff walls are a widely accepted corrective measure used to control and/or isolate impacted groundwater and are routinely approved by the IEPA. Cutoff walls have a long history of reliable performance as hydraulic barriers, provided they are properly designed and constructed. However, if not coupled with a groundwater extraction system, a cutoff wall will provide directional groundwater control only and may result in redistribution of contaminants and potentially GWPS exceedances at new locations.

Cutoff walls are designed to act as hydraulic barriers; as a result, cutoff walls inherently alter the existing groundwater flow system. Changes to the existing groundwater flow system may need to be controlled to maximize the effectiveness of the remedy by, for example, combining a cutoff wall with groundwater extraction to control build-up of hydraulic head upgradient and around the cutoff walls. The effectiveness of a cutoff wall as a hydraulic barrier also relies on the contrast between the hydraulic conductivity of the native geologic materials and the cutoff wall. The most effective barriers have hydraulic conductivity values that are several orders of magnitude lower than the geologic materials they are in contact with. A cutoff wall designed with hydraulic conductivity of 1×10^{-7} cm/sec would be two orders of magnitude lower than the UD with a mean conductivity of 1.3×10^{-5} cm/sec, limiting its performance. Performance and reliability of a cutoff wall in the UD/PMP would also be limited due to the difficulty in delineating the intermittent sandy zones within the unit. Construction of a cutoff wall extending into the UA would be four orders of magnitude lower than the UA, with a mean hydraulic conductivity of 6.8×10^{-3} cm/s and would be an effective containment method in the UA and could improve the performance of a UA extraction system.

Constructing a cutoff wall may be challenging due to the physical site constraints (limited construction area due to the proximity to Newton Lake), particularly if used in combination with an extraction system. In that case, both the extraction system and the cutoff wall would need to be located between the PAP and Newton Lake, which would increase the construction complexity and could result in structural impacts to the embankment dikes, depending on the location of the wall. Specialized construction contractor(s) may be required, which could delay implementation.

Additional data collection and analyses would be required to design a cutoff wall. Construction of only the cutoff wall could be completed within 2 to 3 years. Time of implementation is approximately 5 to 8 years, including characterization, design, permitting and construction. Construction could possibly be accelerated by combining with site closure activities. To attain GWPS, cutoff walls require a separate groundwater corrective measure to operate in concert with the cutoff wall(s). Cutoff walls are commonly coupled with groundwater polishing and/or groundwater extraction as groundwater corrective measures. The time to attain GWPS is dependent on the selected groundwater corrective measure or measures that are coupled with the cutoff walls.

Constructing a cutoff wall at the PAP would require IEPA approval of the CAP permit and, depending on the location, an IDNR dam safety modification permit may be required.

A cutoff wall at the PAP alone would not be a viable corrective measure for the sulfate, lithium, and TDS exceedances at the PAP. However, a cutoff wall may serve to increase the efficiency of a groundwater extraction system by preventing inflow of water from Newton Lake. Therefore, the cutoff wall is being advanced to the CAAA for further evaluation.

5.2.4 Source Control with In-Situ Chemical Treatment

Source control will reduce the mass loading to the groundwater system and implementing additional groundwater corrective measures may reduce the time required to attain the GWPS in the UA. Use of in-situ treatment, either through targeted injection of reactive media or in PRB systems, to transform contaminants into environmentally acceptable forms to attain the GWPS was considered.

In-situ treatment using ion exchange to address sulfate and lithium exceedances in groundwater is not an established or widely accepted groundwater corrective measure; therefore, its performance and reliability are unknown. Regulatory acceptance of this innovative approach to achieving the GWPS is uncertain.

In-situ treatment presents design and construction challenges, including targeted reactive media delivery via injection to the sandier zones in the UD/PMP and the complicated construction that would be required for a PRB system in close proximity to Newton Lake (if possible). Depending upon the location of the PRB system, construction may affect the PAP embankment and/or final cover system and periodic change-outs of ion exchange (IX) resin media may be required.

Additional data collection and analyses would be required to design an in-situ treatment system and bench scale and/or pilot scale testing may be required to demonstrate performance and reliability. Time of implementation is approximately 4 to 6 years after approval of the CAP permit, including characterization, design, permitting, and construction. Timeframes to achieve GWPS are dependent on demonstrations of performance and reliability along with regulatory acceptance. It is not known whether in-situ treatment would reduce the time to attain GWPS in the UA relative to the post-closure timeframe predicted by the groundwater modeling.

Due to the uncertain performance, reliability and potential for not obtaining regulatory acceptance, in-situ chemical treatment is not a viable corrective measure for the sulfate and lithium exceedances at the PAP and is not being advanced to the CAAA for further evaluation.

5.3 Technologies Advanced to CAAA

Based on the evaluations presented above, the following potential corrective technologies are being advanced to the CAAA, individually or in combination, for more detailed evaluations:

- Source control with groundwater polishing;
- Source control and with groundwater extraction; and
- Source control with a groundwater cutoff wall.

Potential Corrective Measure Technology	Evaluation Factors						
	Performance	**Reliability**	**Ease of Implementation**	**Potential Impacts of Remedy** (safety impacts, cross-media impacts, control of exposure to any residual contamination)	**Time Required to Begin and Implement Remedy[1]**	**Time to Attain Groundwater Protection Standards**	**Institutional Requirements** (state/local permit requirements, environmental/public health requirements that affect implementation of remedy)
Source Control with Aquifer Polishing	Performs best paired with source control, which is expected to be completed at the site in 2028. Site conditions are favorable for physical processes of sulfate and lithium. Good performance is expected for physical processes due to the sandy nature of the Uppermost Aquifer. Geochemical process performance may be limited.	Ongoing analysis will evaluate whether the geochemical mechanism has low reversibility, the Uppermost Aquifer and/or the Upper Drift have sufficient capacity, and the hydrogeology is favorable for physical processes. Possibly low reliability for lithium due to reversibility.	Evaluation is underway and is expected to be completed in 2024. Long-term monitoring would be required. Implementing would not require extensive specialized equipment or contractors.	None identified.	Approximately 90 days after CAP permit approval.	Dependent on site specific conditions. Accelerated attainment of GWPS will be limited by the low permeability of the Upper Drift and may not significantly improve attainment of the GWPS in the Uppermost Aquifer to less than the 20 years post-closure predicted by the groundwater model.	IEPA approval of the closure and CAP permits is required.
Source Control with Groundwater Extraction	A widely accepted, routinely approved technology. Performance expected to be effective in the relatively high permeability, sandy, Uppermost Aquifer but would be limited in the low permeability silts and clays of the Upper Drift.	Reliable if properly designed, constructed, and maintained. Reliability is expected to be high in the Uppermost Aquifer but may be affected by the potential need for dense well spacing to ensure overlapping cones of depression and complete groundwater capture in the low permeability silts and clays of the Upper Drift. Groundwater treatment prior to discharge can be considered if indicated by performance monitoring.	Groundwater flow direction in Uppermost Aquifer and physical site constraints (proximity and influence of Newton Lake) may make locating capture wells challenging and would result in a high volume of extracted water. In the Upper Drift, there would likely be a limited zone of influence for capture wells, which would likely require dense well spacing or installation of an extraction trench. Site constraints could make well installation challenging. Specialized contractors are not expected to be needed. Extracted groundwater would require management, possibly including treatment. Groundwater treatment, if needed, may required specialized equipment/contractors.	Alters groundwater flow system and there is some potential for some limited exposure to extracted groundwater.	Design, permitting and construction is expected to take 3 to 4 years after CAP permit approval.	Dependent on site specific conditions. Accelerated attainment of GWPS will be limited by the low permeability of the Upper Drift and may not significantly improve attainment of the GWPS to less than the 20 years post-closure predicted by the groundwater model for source control and aquifer polishing.	IEPA approval of the closure and CAP permits is required. Extracted groundwater discharge may require an NPDES permit modification or permitting and constructing a new outfall, depending on the groundwater flow rates. A IDNR dam safety modification permit might also be required, depending on location of wells and settlement potential.
Source Control with Groundwater Cutoff Wall	Widely accepted and routinely approved technology with good performance if properly designed and constructed, however containment using cutoff walls in the low permeability Upper Drift materials would likely not be effective. If not combined with extraction wells, a cutoff wall will provide directional control only, thus redirecting flow to other areas where GWPS may be exceeded.	Reliable for groundwater directional control in the Uppermost Aquifer if properly designed and constructed. Reliability in the discontinuous sandy deposits of the Upper Drift would be limited by the ability to delineate the sandy deposits.	Widely used, established technology. Groundwater flow direction in Uppermost Aquifer and physical site constraints (proximity and influence of Newton Lake) make locating a cutoff wall challenging. Potential need to locate cutoff wall either upon the existing embankment or upon the (post-closure) final cover would increase the construction complexity. May require specialized construction equipment and delay implementation.	Alters groundwater flow system but does not provide any treatment. Can result in unintended consequences resulting from redirecting contaminants to areas where they are not currently present. May cause structural impacts to the embankment dikes, depending on the location of the wall.	Design, permitting and construction is expected to take 5 to 8 years after CAP permit approval. Implementation could be accelerated by combining with closure construction activities.	Provides groundwater directional control only. Combination with another groundwater corrective measure, such as groundwater extraction or a permeable reactive barrier, may not significantly improve attainment of the GWPS to less than the 20 years post-closure predicted by the groundwater model for source control and aquifer polishing.	IEPA approval of the closure and CAP permits is required. An IDNR dam safety permit may also be required depending on the location of the cutoff wall.
Source Control with In-Situ Chemical Treatment	In-Situ treatment using ion exchange (IX) is not well established for sulfate and lithium, therefore performance is unknown.	Unknown reliability for sulfate and lithium.	Design challenges for a funnel and gate PRB system due to depth, stratigraphy and proximity to the Newton Lake. Challenge to target reactive media delivery in the low permeability Upper Drift for in-situ treatment (injection). Could require periodic change-outs of IX resin media.	Depending on the location of a PRB, it's construction may affect the embankment/final cover system (structural impacts to the dike, inducting settlement, impacts to final cover system, etc.).	May require bench scale and/or pilot scale testing as part of design. Design, permitting and construction is expected to take 4 to 6 years after CAP permit approval.	There is uncertainty regarding whether a permeable reactive barrier would reduce sulfate concentrations to achieve the GWPS. Dependent on conditions specific to the reactive media used and the site. Treatment technology not well understood.	IEPA approval of the CAP permit is required. IEPA approval of this innovative and relatively unproven solution may be challenging. An IDNR dam safety permit may also be required depending on the location of the PRB.

Notes: [1] Time required to begin and implement remedy includes design, permitting and construction.

EXECUTIVE SUMMARY

Groundwater samples collected at the Newton Power Plant (NPP) Primary Ash Pond (PAP) during April 2023 for the Quarter 2, 2023 compliance sampling event (Event 1 [E001]) were evaluated for exceedances of the groundwater protection standards (GWPS) described in Title 35 of the Illinois Administrative Code (35 I.A.C.) § 845.600. Exceedances were identified in the following hydrostratigraphic units and wells:

- Detected uppermost aquifer (UA) Exceedances:
  - Chloride at APW15
  - Sulfate at APW10
- Detected Upper Drift (UD) (potential migration pathway [PMP]) Exceedances:
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - Total dissolved solids (TDS) at APW02, APW04, and APW05S

An alternative source demonstration (ASD) was completed for the chloride exceedance at UA monitoring well APW15. The Illinois Environmental Protection Agency (IEPA) did not concur with the ASD. The non-concurrence was appealed, and the Illinois Pollution Control Board (IPCB) granted a stay on January 18, 2024.

As required by 35 I.A.C. § 845.650(d)(1) this Report characterizes the nature and extent of sulfate, lithium, and TDS, and relevant site conditions to determine how they may affect the corrective measures ultimately selected for the PAP and documents the additional measures taken in accordance with 35 I.A.C. § 845.650(d).

Sulfate (and TDS) above the GWPS was encountered within the two hydrostratigraphic units: the shallow UD and associated PMP, and in the UA where it occurs at it's highest elevation. In both units, the extent of sulfate above the GWPS is defined laterally by existing wells and Newton Lake, and vertically by the presence of low permeability tills or deeper wells that do not have GWPS exceedances. The sulfate concentrations are attenuated physically through dilution and dispersion; and may be geochemically attenuated by sorption to iron oxides. The sulfate and TDS concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1].

Lithium above the GWPS was encountered only within the shallow UD at APW02. The extent of lithium above the GWPS is currently being further defined laterally with additional wells but is ultimately defined by Newton Lake. Vertically, the extent of lithium above the GWPS is limited by presence of low permeability tills and defined by deeper wells that do not have GWPS exceedances. The lithium concentrations are attenuated physically through dilution and dispersion and may be geochemically attenuated by sorption to and incorporation into clay minerals. The lithium concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1].

1. INTRODUCTION

35 I.A.C. § 845.650(d)(1) requires the owner or operator of a coal combustion residuals (CCR) surface impoundment (SI) to characterize the nature and extent of a release and relevant site conditions that may affect the remedy ultimately selected for a CCR SI if any constituent regulated under 35 I.A.C. § 845 is found to exceed the GWPS. This report documents the nature and extent of constituents detected above the GWPS that are attributable to the NPP PAP.

The groundwater data and analysis in this report includes results from historical sampling (initiated in 2015) through E001, which was completed on April 28, 2023. Results of the E001 event were submitted and placed in the facility's operating record by August 7, 2023 as required by 35 I.A.C. § 845.800(d)(15), within 60 days of receiving final laboratory analytical data [2]. The statistical determination presented in the report identified the following exceedances of the GWPS at compliance groundwater wells in the following hydrostratigraphic units:

- Detected UA Exceedances:
  - Chloride at APW15
  - Sulfate at APW10
- Detected UD/PMP Exceedances:
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - Total dissolved solids (TDS) at APW02, APW04, and APW05S

An Alternative Source Demonstration (ASD), as allowed by 35 I.A.C. § 845.650(e) was completed for the chloride exceedance at UA monitoring well APW15 [3]. The Illinois Environmental Protection Agency (IEPA) did not concur with the ASD in a letter dated November 7, 2023 due to the following data gaps:

1. Source characterization of the CCR at the PAP must include total solids sampling in accordance with SW846.
2. Hydraulic conductivities from laboratory or in-situ testing must be collected, analyzed and presented with the hydrogeologic characterization of bedrock unit.
3. Characterization to include sample and analysis in accordance with 35 I.A.C. § 845.640 of alternative source must be provided with the ASD.

On December 15, 2023, Illinois Power Generating Company (IPGC) submitted a Petition for Review [4] of the non-concurrence with the chloride ASD and Motion for Stay to the IPCB. The IPCB granted a stay on January 18, 2024. Therefore, the nature and extent of chloride is not discussed in this document. This Nature and Extent Report discusses in detail the extent of the sulfate, lithium, and TDS exceedances as well as a geochemical conceptual site model (GCSM) describing the nature of these exceedances.

2. UNIT BACKGROUND

2.1 Site Location and Description

The NPP is located in Jasper County in the southeastern part of central Illinois, approximately seven miles southwest of the town of Newton (**Figure 2-1**). The NPP operates as a coal-fired power plant with three CCR units present, including the PAP and two landfills: the Phase 1 Landfill (LF 1) located northwest and west of the PAP, and the Phase 2 Landfill (LF 2) located to the west of the PAP. The PAP is located within Section 26 and the west half of Section 25, Township 6 North, Range 8 East. The PAP is located south of the NPP and surrounded by Newton Lake to the south, east, and west (**Figure 2-2**). Beyond the lake is additional agricultural land.

2.2 Description of CCR Unit

The PAP is an unlined CCR SI used to manage CCR and non-CCR waste streams at the NPP. The PAP was constructed in 1977 and has a design capacity of approximately 9,715 acre-feet. There is also a non-CCR 83.6 acre-feet Secondary Pond located immediately south of the PAP. The PAP has a surface area of 404 acres and the Secondary Pond has an area of 9.3 acres. The PAP currently receives stormwater runoff, bottom ash, fly ash, and low-volume wastewater (LVW) from the plant's two coal-fired boilers. The SI is operated per National Pollutant Discharge Elimination System (NPDES) Permit No. IL0049191, Outfall 001 (located at the Secondary Pond).

Prior to PAP construction, an incised stream gully existed at the site of the PAP. Areas within the impoundment were excavated during construction for native materials used to build the containment berms in 1977.

Initial operation of the NPP, beginning with Unit 1 being put into service in 1977, included combustion of Illinois coal until 1997-1998, at which point the plant switched to low sulfur coal from the Powder River Basin. Both fly and bottom ash were sluiced wet to the PAP until 1979 when the wet scrubber (including sodium carbonate injection) came online. The fly ash was then mixed with the scrubber cake and placed in the Phase I landfill while bottom ash continued to be sluiced to the PAP. The scrubber was shut down in the Fall of 1996 and fly ash was sluiced wet to the PAP again. Fly ash and bottom ash have both been sluiced to the PAP since the plant began operation in 1977. Emission controls consisting of injection of halogenated activated carbon to reduce mercury emissions were implemented prior to 2009 under an agreement with IEPA. The Newton Landfill Phase 1 (closed) and Phase 2 (operational) receive the wastes generated from the emissions controls. Review of historic aerial imagery of the PAP (observations summarized in **Figure 2-3**) illustrate the extent of CCR deposition through time as well as potential CCR variability (based on observed differences in color). Characterization of the CCR material including total metals analysis of eight samples of materials within the PAP and completion of monitoring wells screened within the CCR was completed in areas of the PAP that were safely accessible in 2021 to meet the requirements of 35 I.A.C. § 845 (**Figure 2-4**) (Hydrogeologic Site Characterization Report [5]).

2.3 Geology and Hydrogeology

Significant site investigation has been completed at the NPP to characterize the geology, hydrogeology, and groundwater quality. Based on extensive investigation and monitoring, the PAP has been well characterized and detailed in the Hydrogeologic Site Characterization Report [5].

2.3.1 Hydrostratigraphic Units

Materials at the site have been categorized into six hydrostratigraphic units at the PAP based on stratigraphic relationships, geologic composition, and common hydrogeologic properties. The units, listed from surface downward, are summarized as follows:

- **CCR:** CCR consists of fly and bottom ash within the PAP and may be present from the surface (approximately 545 to 555 feet[1]) to a minimum elevation of approximately 485 feet NAVD88 (**Figure 2-5**). CCR material is lowest in elevation along a historic drainage feature that runs approximately through the center of the PAP. Groundwater elevations measured in piezometers screened within the PAP indicate that the phreatic surface ranges from approximately 535 to 547 feet, which is above groundwater measured outside the CCR unit in the surrounding monitoring wells.
- **Upper Drift (UD)/Potential Migration Pathway (PMP):** The UD is composed of the low permeability silts and clays of the Peoria Silt and Sangamon Soil and the sandier soils of the Hagarstown Member (*i.e.,* PMP).
  - **Hagarstown Member/PMP:** The Hagarstown Member consists of discontinuous sandier deposits of the UD, where present, and overlies the Vandalia Till.
- **Upper Confining Unit (UCU):** This unit consists of the low permeability clay and silt of the Vandalia Till Member (Vandalia Till).
- **Uppermost Aquifer (UA):** This unit is composed of the Mulberry Grove Formation, which has been classified onsite as poorly graded sand, silty sand, clayey sand, and gravel.
- **Lower Confining Unit (LCU):** This unit is comprised of low permeability silt and clay of the Smithboro Till Member (Smithboro Till) and the Banner Formation.
- **Bedrock Unit:** Shale bedrock of the Pennsylvanian-age Mattoon Formation [6] was encountered at the NPP during recent and historical investigations. Based on boring logs, the bedrock surface elevation at the NPP ranges from 408 feet (B141) to 445 feet (APW13) (Ramboll, 2023). The locations of these wells and measured bedrock elevations indicate the bedrock surface is highest in the southeast portion of the site and slopes downward to the west and north beneath the PAP.

2.3.2 Uppermost Aquifer

The UA includes the Mulberry Grove Member in the vicinity of the PAP. Groundwater monitoring for the UA is focused on this zone because it is continuous, exhibits moderate permeability, and is likely to indicate potential impacts from the PAP. The top of UA was evaluated with respect to the location restrictions in 2018 [7] and provided in **Figure 2-6**. Based on the geologic information, the top of the aquifer is highest in elevation nearest the base of the CCR in the eastern portion of the pond (along a NW-SE trending line between APW05 to APW10), with an elevation of approximately 482 feet. The top of the UA is separated from overlying CCR material by the low permeability Vandalia Till which was encountered at thicknesses up to 59 feet and an average thickness of 26 feet (**Figures 2-7** to **2-9**). The base of the UA is the top of the LCU, which contains the low permeability Smithboro Till and the Banner Formation.

[1] All elevations in this report are referenced to North American Vertical Datum of 1988 (NAVD88) unless otherwise noted.

2.3.3 Potential Migration Pathways

The UD consists mostly of low permeability clays and silts of the Peoria Silt, Sangamon Soil, and sandy clay of the Hagarstown Member which also includes discontinuous sand lenses. Monitoring wells APW02, APW03, and APW04 are screened in sandy clay at the interface with the Vandalia Till, while APW05S and APW12 are screened within the sandier deposits of the UD. These wells are generally screened at similar elevations and provide representative groundwater samples to monitor shallow PMPs adjacent to the PAP.

2.3.4 Regional Bedrock Geology

Bedrock investigation at the site has been limited given the depth to bedrock, presence of low permeability confining units underlying the UA and above the bedrock, the low permeability of the bedrock unit, and generally non-potable groundwater. There are no known monitoring wells or production wells screened within the bedrock at NPP. Bedrock has been encountered at three borings on-site (APW13, APW14, and historic boring B141), with elevations ranging from 408 feet (B141) to 445 feet (APW13). A literature review was completed to supplement the site geology. Groundwater available from bedrock units is mostly mineralized and rarely used as a source for potable water [8]. Lithium is naturally occurring in shale bedrock and overlying regolith and is released to groundwater during weathering processes [9]. Regional investigations of the Illinois Basin have also identified bedrock (specifically brines within the bedrock formations) as a source of chloride in groundwater [10, 11]. Studies by Cartwright [12] and Siegel [13] indicate that groundwater migrates toward the center of the Illinois Basin and discharges upward through overlying confining units. The "Saline groundwater and brines can be brought near or to the land surface by natural conditions, such as migrating up prominent fractures and/or faults in bedrock, or by anthropogenic activities, such as exploration for and exploitation of petroleum. The mixing of upward-migrating saline groundwater with fresh groundwater from shallow aquifers can make groundwater from private wells undrinkable and can present a very expensive problem for municipalities" [14]. A saline spring was identified in Clay County [10] approximately 10 miles south of the NPP and is adjacent to the Clay City Anticline which runs north into Jasper County and east of the NPP. Concentrations of chloride in groundwater collected from the Pennsylvanian shale in Jasper County range from 100 to 5,000 milligrams per liter (mg/L) [11].

2.3.5 Water Table Elevation and Groundwater Flow Direction

The elevations of water within the PAP (as observed in XPW01 through XPW04, and XSG01) are greater than the surrounding areas. The phreatic surface within the PAP in 2023 averaged 539 feet, ranging from approximately 547 feet in XPW02 (located along the northern portion of the PAP) to 530 feet in XSG01 (staff gage located along the southern portion of the PAP) (**Figure 2-10)**.

As indicated in Section 2.3.2 the groundwater in the UA is separated from overlying CCR material by an average thickness of 26 feet of the low permeability Vandalia Till. Groundwater flow in the UA is generally from the north near background wells APW05 and APW06 to the southwest toward a historic drainage feature and southeast toward Newton Lake. Specifically, groundwater flow is north to south beneath the center of the PAP (from APW05/APW06 toward APW09/APW15). Beneath the western portion of the PAP, flow is west to southwest converging towards a former surface drainage feature located west of the PAP (**Figure 2-10**) and an area where the UA is lowest in elevation and has the highest hydraulic conductivity. Beneath the eastern portion of the PAP, groundwater flows east to southeast (from APW05 toward APW11-

APW14). Groundwater elevations exhibit limited variability, generally less than one to two feet per year. Spatially across the PAP they range from approximately 490 feet in the southern portion of the site to 530 feet in the northern portion of the site. Flow directions are generally consistent between seasons [5].

Groundwater elevations in PMP wells are above those in the UA, exhibit more variability, (1-4 feet per year), and range from approximately 518 feet (APW05S) to 535 feet (APW05S). Groundwater elevations within the UCU, LCU, and bedrock unit are unknown because no wells are screened within these low hydraulic conductivity units. Groundwater flow within the aquitards of the UCU and LCU will be primarily vertical based on heads above and below these units.

2.3.5.1 Vertical Hydraulic Gradients

Vertical hydraulic gradients calculated using available groundwater elevation data from February to August 2021 at nested well locations within the UD (*i.e.,* PMP) and UA wells indicated downward gradients [5], which was consistent with historical results [15]. Recent data collected through April 2023 is also consistent with these results. The results of the vertical hydraulic gradient calculations for these hydrostratigraphic units are summarized below:

- UD (*i.e.,* PMP) to UA:
  - Gradients calculated between APW05S (PMP) and APW05 (UA) were downward for all events.
  - Gradients calculated between APW04 (PMP) and APW10 (UA) were downward for all events.
  - Gradients calculated between APW03 (PMP) and APW09 (UA) were downward for all events.
  - Gradients calculated between APW02 (PMP) and APW17 (UA) were downward for all events.

2.3.5.2 Impact of Surface Water Bodies on Groundwater Flow

The surface water elevation at Newton Lake measured from February 15, 2021 to October 9, 2023 ranged from 503.56 to 504.84 feet at location SG02 near the outfall from the Secondary Pond. Groundwater flow in the UA generally flows southwest across the PAP with potentiometric surface elevations at downgradient wells around 491 feet (approximately 10-15 feet lower than the Newton Lake elevation). The separation observed in groundwater and surface water elevations (and observed downward vertical gradients) indicates groundwater within the UA does not flow into Newton Lake along the western portion of the site.

Groundwater elevations observed at APW10 located on the east side of the site are approximately 2 feet higher than surface water in Newton Lake (506 feet versus 504 feet) indicating groundwater migrates toward the Lake along the eastern boundary of the Unit. Based on the stratigraphic interpretations, the UA slopes upward in this area and approaches the former land surface, now beneath Newton Lake. As illustrated in cross-section B-B' (**Figure 2-8**), the UA may intersect the base of Newton Lake.

2.3.6 Hydraulic Conductivities

2.3.6.1 Field Hydraulic Conductivities

Field hydraulic conductivity tests were conducted by Ramboll during the 2021 investigation [5]. The results are summarized in **Table 2-1**, and discussed below:

- **CCR**: Results of field hydraulic tests in wells screened within the CCR (XPW01 through XPW04) ranged from 1.0×10^{-3} to 2.3×10^{-1} centimeters per second (cm/s), with a geometric mean of 2.0×10^{-2} cm/s.
- **UD**: Previous field hydraulic conductivity tests conducted by NRT in 2017 in wells screened within the Sangamon Soil of the UD (APW02, APW03, and APW04) ranged from 5.14×10^{-6} to 4.53×10^{-5} cm/s, with a geometric mean hydraulic conductivity of 1.5×10^{-5} cm/s [15].
  - **PMP**: Results of field hydraulic tests in wells screened within the Hagarstown PMP (APW05S and APW12) ranged from 6.1×10^{-4} to 1.5×10^{-2} cm/s, with a geometric mean hydraulic conductivity of 3.1×10^{-3} cm/s.
- **UCU**: No field hydraulic conductivity tests were performed as there are no wells screened within the UCU.
- **UA**: Results of field hydraulic tests in wells screened within the UA (APW11, APW13, APW14, APW15, APW16, APW17, and APW18) ranged from 2.0×10^{-4} to 1.5×10^{-1} cm/s, with a geometric mean of 6.8×10^{-3} cm/s. Previous field hydraulic conductivity tests conducted in 2017 obtained similar results with a geometric mean hydraulic conductivity of 1.2×10^{-3} cm/s [15]. The highest conductivities are measured in APW15, APW16, and APW17, which is consistent with groundwater flow toward these wells. In addition, the grain-size analyses of the UA materials from two samples collected at APW17 were amongst the highest observed at the Site, with sand and gravel contents of 91.1 and 93.3 percent.
- **LCU**: No field hydraulic conductivity tests were performed as there are no wells screened within the LCU.
- **Bedrock**: No field hydraulic conductivity tests were performed as there are no wells screened within the bedrock unit.

2.3.6.2 Laboratory Hydraulic Conductivities

Falling head permeability tests (ASTM D5084 Method F) were performed in the laboratory on samples collected during the 2021 investigations [5]. The results are summarized in **Table 2-2** and discussed below.

- **CCR**: Eight samples were collected from CCR borings XPW01 through XPW04, located within the PAP. However, the two samples collected from XPW02 (8 to 8.5 and 16.5 to 17 feet bgs) were general fill not CCR fill and are not included in summary of CCR characteristics. Laboratory falling head permeability test results for the six CCR samples indicated a geometric mean vertical hydraulic conductivity of 3.1×10^{-4} cm/s with a range of 1.6×10^{-5} to 1.3×10^{-3} cm/s.
- **UD**: One sample was collected from the Sangamon Soil at borings APW11 and APW15. Laboratory falling head permeability test results in the UD indicated a geometric mean vertical hydraulic conductivity of 5.9×10^{-8} cm/s and ranged from 3.1×10^{-8} to 8.6×10^{-8}

cm/s. These values are lower than previous samples collected in 2017 from APW02 AND APW04, which reported a geometric mean hydraulic conductivity of 1.3 x 10^{-5} cm/s [15].

- **PMP**: Three samples were collected from the Hagarstown Member, a PMP within the UD, at borings APW12 and APW13. Laboratory falling head permeability test results for the Hagarstown Member indicated a geometric mean vertical hydraulic conductivity of 3.5 x 10^{-5} cm/s and ranged from 1.1 x 10^{-7} to 9.6 x 10^{-5} cm/s.
- **UCU**: Four samples were collected from the Vandalia Till at borings APW14, APW17, SB300/APW18, and SB301. Laboratory falling head permeability test results for the UCU samples indicated a geometric mean vertical hydraulic conductivity of 6.7 x 10^{-8} cm/s and ranged from 3.3 x 10^{-8} to 9.7 x 10^{-8} cm/s. These values are similar to a previous investigation completed in 1997 that reported hydraulic conductivity values ranging from 6.3 x 10^{-9} to 2.1 x 10^{-8} cm/s with a geometric mean hydraulic conductivity of 1.1 x 10^{-8} cm/s [8].
- **UA**: Five samples were collected from the Mulberry Grove Formation at borings APW13, APW15, APW17, and APW18. Laboratory falling head permeability test results for the Mulberry Grove Formation indicated a geometric mean vertical hydraulic conductivity of 3.2 x 10^{-4} cm/s and ranged from 3.5 x 10^{-6} to 7.2 x 10^{-4} cm/s.
- **LCU**: Eight samples were collected from the glacial tills of the Smithboro Till at borings APW11, APW12, APW14, APW15, APW18, and SB301. Laboratory falling head permeability test results for the Smithboro Till indicated a geometric mean vertical hydraulic conductivity of 9.3 x 10^{-8} cm/s and ranged from 2.4 x 10^{-8} to 2.7 x 10^{-7} cm/s. No samples were collected from the Banner Formation of the LCU.
- **Bedrock**: No bedrock samples were analyzed.

2.4 Groundwater Monitoring

The monitoring system for the PAP is shown on **Figure 2-2** and consists of two background monitoring wells (APW05 and APW06), 16 compliance monitoring wells (APW02, APW03, APW04, APW05S, APW07, APW08, APW09, APW10, APW11, APW12, APW13, APW14, APW15, APW16, APW17, and APW18), and two temporary water level only surface water staff gages (XSG01 and SG02) to monitor potential impacts from the PAP [16]. These monitoring wells are screened within the UD/PMP (APW02, APW03, APW04, APW05S, and APW12) and the UA (APW05, APW06, APW07, APW08, APW09, APW10, APW11, APW13, APW14, APW15, APW16, APW17, and APW18) along the perimeter of the PAP. Porewater samples are collected from locations XPW01 and XPW02 on the northern side of the PAP, and from XPW03 and XPW04 on the northeastern side of the PAP (**Figure 2-2**).

2.5 Hydrogeologic Conceptual Site Model

The HCR [5] and information provided above forms the foundation of the PAP hydrogeological setting. The PAP overlies a potential recharge area for the underlying transmissive geologic media, which are composed of unlithified deposits. Recharge migrates downward into and through the UD and UCU into the UA. In locations where recharge intersects the Hagarstown, it mixes with groundwater and migrates within the unit, which is also monitored as a PMP in addition to the UA.

The silts of the UD and sands of the PMP are hydraulically connected and considered a single hydrostratigraphic unit although groundwater migration will be variable based on localized

hydraulic properties. The groundwater flow in the silts and clays of the UD and confining units of the UCU, LCU, and BCU is expected to be primarily vertical. The Hagarstown member PMP and sands of the UA are the primary units where the majority of the horizontal groundwater migration is expected to occur. The geologic conceptual model for the site used for the groundwater modeling [17] consists of the following layers:

- Silts and Clays (UD) – silt and clayey silt of the Peoria Silt and Sangamon Soil which extends beneath the topsoil.
- Discontinuous sands (PMP) – sandier soils of the Hagarstown Member.
- Vandalia Till (UCU) – a thick layer of low permeability till consisting of the Vandalia Till.
- Sands (UA) – sands and gravels of the Mulberry Grove Formation, laterally continuous sand and gravel deposit identified beneath the site.
- Smithboro Till (LCU) – composed of lean clay Smithboro Till and Banner Formation.
- BCU – lowermost unit identified at the site and underlies all unlithified deposits. This unit is composed of low permeability shale of the Mattoon Formation.
- Alluvial deposits of the Cahokia formation may replace UD and UCU deposits along the southeastern boundary of the PAP.

The United States Geological Survey (USGS) National Map places the NPP within the upper Illinois-Little Wabash watershed subbasin (Hydrologic Unit Code 05120114). The PAP hydrogeologic CSM extent is bounded by a hydrological catchment (watershed) divide to the east based on watershed data from USGS. The Newton Lake water levels are managed such that they remain at an elevation between 504.23 and 504.82 feet. Newton Lake is the receiving body of water for surface water.

Precipitation infiltrates and recharges the groundwater table throughout the site and upgradient. Groundwater in the UD migrates downward into the discontinuous sands of the Hagarstown Formation. The Hagarstown Formation, where present, is considered a PMP for groundwater adjacent to the PAP and localized lateral migration of groundwater may occur. The sands of the UA are separated from the Hagarstown Formation PMP and the base of CCR in the PAP by the laterally continuous low permeability UCU. The UA receives water from the overlying geologic units and potentially through its interpreted connection with Newton Lake. Water that percolates downward from layers overlying the UA is most likely to travel laterally from the site within the UA due to the lateral continuity, relatively high permeability, and horizontal gradients present within the UA as described above. Further downward migration is also limited by the relatively thick and low permeability LCU.

Based on the geology and hydrogeology, monitoring wells at the PAP can be separated into three distinct groupings which exhibit similar geologic and hydraulic characteristics. Monitoring well groupings are summarized as follows:

- UD/PMP wells: shallow wells (generally less than 40 feet bgs) screened in low to moderate permeability materials (generally $\leq 10^{-4}$ cm/s) including APW02, APW03, APW04, and APW05S. Based on the water levels measured within the PAP, UD/PMP wells are downgradient of the PAP.

Eastern UA wells: wells located on the eastern half of the PAP (APW05, APW10, APW11, APW13, and APW14) where the top of the UA is slightly shallower (~40 to 60 feet bgs). Results indicate that the hydraulic conductivity of the UA is lowest where the UA is shallowest at monitoring wells APW05 and APW10. Groundwater flow directions indicate these wells are currently downgradient of the former drainage feature that was present prior to construction of the PAP.

- Western UA wells: wells located on the western half of the PAP (APW06, APW07, APW08, APW15, APW16, APW17, and APW18) where the top of the UA is slightly deeper (~60 to 90 feet bgs). Several of these wells had high hydraulic conductivities. Groundwater flow directions indicate these wells represent groundwater from the western portion of the PAP and from areas located west of the PAP.

3. OCCURRENCE AND DISTRIBUTION OF GROUNDWATER EXCEEDANCES (EXTENT)

Results from groundwater samples collected from the PAP during E001 were received on June 8, 2023. In accordance with 35 I.A.C. § 845.610(b)(3)(C), comparison of statistically derived values with the GWPSs described in 35 I.A.C. § 845.600 to determine exceedances of the GWPS was completed [2]. Exceedances for which an ASD was not completed include the following parameters and wells by hydrostratigraphic unit:

- UA (**Figure 3-1**):
  - Sulfate at APW10
- UD (PMP; **Figure 3-2**):
  - Lithium at APW02
  - Sulfate at APW02, APW04, and APW05S
  - TDS at APW02, APW04, and APW05S

3.1 Additional Investigation to Define Nature and Extent

Following initial sampling in 2021, potential exceedances of the GWPS were identified for the parameters and locations identified above [18]. Additional investigation was completed in 2021 to collect soil samples and surface water samples to further evaluate the concentrations and potential attenuation mechanisms near the PAP (**Appendix A** and **Appendix B**).

A total of seven borings were advanced adjacent to locations with potential exceedances (APW02, APW04, APW05S, and APW10), and porewater wells (XPW01 and XPW04). Solids samples were collected and analyzed for the following:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld x-ray diffraction (XRD) Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

In addition, 28 surface water samples were collected to characterize the water quality in Newton Lake. Surface water samples were analyzed for 35 I.A.C. § 845.600 parameters (total and dissolved), ferrous and ferric iron, major ions, and monitored natural attenuation parameters. Data from this investigation has been incorporated into this report where applicable.

3.2 Extent in the Uppermost Aquifer

Groundwater samples are evaluated quarterly and exceedances are identified following comparison of lower confidence limits (LCLs) to the GWPSs described in 35 I.A.C. § 845.600. The

LCLs vary as the dataset is updated to include additional quarterly events (**Table 3-1**). The discussion below includes ranges of concentrations measured in wells with exceedances, because there is no single value for LCLs.

3.2.1 Sulfate

Sulfate exceedances in the UA are limited to APW10. Monitoring well APW10 is located on the southeast berm of the unit, between the PAP and Newton Lake. Concentrations of sulfate in APW10 range from 390 to 540 mg/L. The extents of concentrations above the GWPS are defined laterally in the UA to the southwest by monitoring well APW13 (**Figure 3-1**). The boring log from APW12 (location shown on **Figure 2-10**) indicates that the UA is not present northeast of APW10, and exceedances are not expected to extend a significant distance in this direction due to observed groundwater flow directions and the absence of UA materials observed at APW12. Newton Lake is located approximately 100 feet downgradient of APW10 and comparison of water elevations indicates that groundwater migrates toward Newton Lake. The extent of sulfate is defined downgradient by surface water samples collected near APW10 which indicate concentrations of sulfate are 39 mg/L (**Appendix B**), comparable to concentrations measured for sulfate in ambient portions of the lake distant from the PAP.

Downward migration of sulfate in the UA at APW10 is inhibited by the underlying Smithboro Till which has a thickness of greater than 10 feet. Vertical permeability tests completed on samples of the LCU beneath the UA indicate a geometric mean vertical hydraulic conductivity of 9.3×10^{-8} cm/s with a range from 2.4×10^{-8} to 2.7×10^{-7} cm/s. This is very low relative to the horizontal hydraulic conductivity measured within APW10 (5.5×10^{-4} cm/s). The significant contrast in permeability (greater than two orders of magnitude) indicates groundwater will preferentially migrate horizontally toward Newton Lake and the elevated sulfate concentrations will not extend into the underlying till and shale bedrock.

3.3 Extents in Upper Drift /Potential Migration Pathways

3.3.1 Sulfate

Concentrations of sulfate exceed the GWPS (400 mg/L) at UD/PMP wells APW02, APW04, and APW05S. Concentrations and the extent of sulfate at these locations (**Figure 3-2**) are summarized as follows:

- APW02 – Concentrations range from 1,500 to 3,200 mg/L. The lateral and downgradient extent of sulfate concentrations near APW02 is currently being investigated but is ultimately limited downgradient by Newton Lake. Concentrations of sulfate in Newton Lake near this location were 38 mg/L (**Appendix B**), comparable to concentrations measured for sulfate in ambient portions of the lake distant from the PAP. Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low sulfate concentrations reported in APW17 (non-detect to 64 mg/L) which is nested with APW02 and screened in the UA beneath the PMP.
- APW04 – Concentrations range from 760 to 990 mg/L. The lateral extent of sulfate concentrations in the UD near APW04 is defined to the north by APW12 (56 to 712 mg/L) and to the southwest by APW03 (110 to 190 mg/L). APW04 is located approximately 100 feet from Newton Lake. As discussed for APW10, concentrations of sulfate in the adjacent area of

Newton Lake were 39 mg/L. Vertical extents at this location were discussed in the previous section regarding APW10.

- APW05S – Concentrations range from 200 to 2,100 mg/L. The lateral and downgradient extent of sulfate concentrations near APW05S is currently being investigated to the north and east but is defined by APW12 (56 to 712 mg/L) to the east. Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (range of 6.3×10^{-9} to 9.7×10^{-8} cm/s measured in the till onsite). Lack of vertical migration is also supported by the low sulfate concentrations reported in APW05 (non-detect at 15 mg/L) which is nested with APW05S and screened in the UA beneath the PMP.

3.3.2 Lithium

Monitoring well APW02 is located near the southwest corner of the PAP and screened within the low conductivity materials of the UD. Concentrations of lithium range from 0.079 to 0.3 mg/L. The lateral and downgradient extent of lithium concentrations near APW02 is limited downgradient by Newton Lake and additional data is currently being collected to further evaluate the extent of lithium and sulfate concentrations in groundwater. Concentrations of lithium were not detected in Newton Lake near this location (<0.02 mg/L; **Appendix B**). Vertically, the extent of lithium is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low lithium concentrations reported in APW17 (non-detect to 0.0099 mg/L) which is nested with APW02 and screened in the UA beneath the PMP.

3.3.3 Total Dissolved Solids

TDS results indicate the mass of dissolved material in the groundwater and is a representation of multiple constituents present in the groundwater. Typically, major ions (such as sulfate) represent the primary contributors to TDS. TDS exceeded the GWPS at APW02 and APW04. Concentrations and the extent of TDS at these locations is summarized as follows:

- APW02 – Concentrations range from 1,910 to 5,500 mg/L. The lateral and downgradient extent of TDS concentrations near APW02 is currently being investigated but is limited downgradient by Newton Lake. Concentrations of TDS in Newton Lake near this location were 170 mg/L (**Appendix B**). Vertically, the extent of sulfate is limited by the low permeability Vandalia Till which underlies this well (APW17 [40 to 42 feet bgs], 3.4×10^{-8} cm/s), and is supported by the low TDS concentrations reported in APW17 which is nested with APW02 and screened in the UA beneath the PMP.
- APW05S - Concentrations range from 3,200 to 4,000 mg/L. The lateral and downgradient extent of TDS concentrations near APW05S is currently being investigated to the north and east but is defined by APW12 (990 to 1,740 mg/L) to the east. Vertically, the extent of TDS is limited by the low permeability Vandalia Till which underlies this well (range of 6.3×10^{-9} to 9.7×10^{-8} cm/s measured in till onsite) and is supported by the low TDS concentrations reported in APW05 (470 to 1,000 mg/L) which is nested with APW05S and screened in the UA beneath the PMP. Concentrations above the GWPS do not extend past the waste boundary downgradient as evidenced by concentrations in wells APW03 and APW04.

4. GEOCHEMICAL CONCEPTUAL SITE MODEL (NATURE)

A GCSM was developed to describe the conditions of the groundwater in the vicinity of the NPP PAP and is summarized here (full analysis presented in **Appendix C**). The GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. Only parameters that have exceeded the GWPS in PAP groundwater and will be addressed in the corrective action plan are included in the GCSM. As discussed in previous sections the exceedances observed at the PAP include sulfate, TDS, and lithium.

The GCSM includes two hydrostratigraphic units: the shallow UD/PMP and the deeper UA. The UA is shallowest (*i.e.*, in closest proximity to the upper drift/primary migration pathway) on the east side of the PAP. Groundwater in the UD/PMP and eastern UA wells tend to be geochemically similar: groundwater from these locations tends to be more oxidizing, exhibit lower pH, and have a cation signature dominated by calcium and magnesium. Groundwater in the rest of the UA tends to be more reducing (exhibiting higher dissolved iron concentrations), have higher pH, and have a greater contribution of sodium and potassium to the cation signature. These results suggest some degree of hydraulic connection between the UD/PMP and UA east of the PAP.

Sulfate is the major contributor to TDS in the PAP groundwater. Therefore, processes that control sulfate concentrations also control TDS. Elevated sulfate concentrations were observed in shallow groundwater wells (screened in the upper drift/primary migration pathway) and UA wells located east of the PMP. Sulfate in CCR porewater and the UD/PMP groundwater is correlated with sodium, indicating that dissolution of sodium sulfate from the CCR material is the primary source of sulfate to the CCR porewater. Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. Potential sulfate attenuation mechanisms at the NPP PAP include sorption to solid-phase iron oxides. Based on results from laboratory batch testing, sulfate sorption may be more likely in the UA.

Lithium concentrations in groundwater are highest in UD/PMP and eastern UA groundwater. Although lithium was identified in solid samples located both upgradient and downgradient of the PAP, the similar distributions of lithium and sulfate suggest that CCR porewater is the primary source of lithium to the groundwater. The difference in groundwater lithium concentrations may be due to variability in porewater concentration or in attenuation to aquifer solids. Lithium in groundwater may be attenuated by sorption to exchangeable sites (readily reversible) or incorporation in clay mineral matrices (poorly reversible). According to results from laboratory batch testing, lithium may sorb to both UA/PMP and UA solids.

5. COMBINED GEOCHEMICAL AND HYDROGEOLOGIC CONCEPTUAL SITE MODELS

5.1 Sulfate and TDS Conceptual Site Model

The CSM describing current conditions at the PAP combining the hydrogeologic and geochemical CSMs for sulfate and TDS is as follows. Surface water within the PAP comes into contact with CCR and once it enters the pore spaces within the CCR we characterize it as porewater within the unlined CCR unit. Porewater containing elevated concentrations of sulfate mixes with groundwater of the UD. Groundwater within the UD/PMP in the vicinity of the PAP travels horizontally outward from the PAP, ultimately migrating toward Newton Lake, or vertically into the clay of the UCU that separates the UD from the UA. Sulfate concentrations are attenuated physically through dilution and dispersion; and may be geochemically attenuated by sorption to iron oxides. The limit of sulfate exceedances is defined by wells in the UA with concentrations below the GWPS and Newton Lake, where sulfate concentrations near APW10 are 39 mg/L (**Appendix B**). The sulfate concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1]. Sulfate exceedances of the GWPS have been observed in 3 of 5 UD wells and 1 of 13 UA wells. The presence or absence of exceedances can be attributed to variability in both sulfate concentration within the CCR of the PAP and the extent of water migration between the UD/PMP and UA.

5.2 Lithium Conceptual Site Model

The CSM describing current conditions at the PAP combining the hydrogeologic and geochemical CSMs for lithium is as follows. Surface water within the PAP comes into contact with CCR and once it enters the pore spaces within the CCR we characterize it as porewater within the unlined CCR unit. Porewater containing elevated concentrations of lithium mixes with groundwater of the UD/PMP. Groundwater within the UD in the vicinity of the PAP travels horizontally outward from the PAP, ultimately migrating toward Newton Lake, or vertically into the clay of the UCU that separates the UD from the UA. Lithium concentrations are attenuated physically through dilution and dispersion and may be geochemically attenuated by sorption to and incorporation into clay minerals. The lithium exceedance is limited to one location (APW02) and is being further investigated laterally, but is limited in extent by Newton Lake, where concentrations in surface water were < 0.02 mg/L (**Appendix B**). The lithium concentrations in Newton Lake were evaluated and they do not present unacceptable risk [1]. Lithium exceedances of the GWPS have only been observed in UD well APW02 located along the western side of the PAP, which is the same side of the PAP where the highest concentrations of lithium were observed in porewater (XPW01), indicating exceedances at APW02 may be a result of proximity to portions of the PAP where CCR porewater contains relatively higher concentrations of lithium.

6. CONCLUSIONS AND FUTURE ACTIVITIES

In accordance with 35 I.A.C. § 845.650(d)(1), the nature and extent of GWPS exceedances of sulfate, TDS, and lithium have been described in sufficient detail to support a complete and accurate assessment of the corrective measures necessary to effectively clean up all releases from the PAP.

The lateral extents of exceedances are illustrated in **Figures 3-1 and 3-2**. As discussed in Sections 3.3.1 and 3.3.2, the horizontal delineation of lithium at APW02 is ongoing, as well as additional characterization of sulfate exceedances at APW04, APW05S, and APW10. Wells will be installed upgradient of APW05S; downgradient of APW02, APW04, and APW10; and along the NEW PAP waste boundary, adjacent to APW02 in 2024. Findings from the installation and sampling of these additional wells will be incorporated into the final Corrective Action Plan Permit application, which will be submitted in 2025.

Sulfate was selected for modeling source control presented in the Final Closure Plan and was identified as a surrogate for the exceedances of lithium and TDS, as described in the Groundwater Modeling Report (GMR) [17]. For modeling purposes it was assumed that sulfate would not significantly sorb or chemically react with aquifer solids (soil adsorption coefficient [Kd] was set to 0 milliliters per gram [mL/g]), which is a conservative estimate for predicting contaminant transport times in the model. Additional geochemical modeling will be completed to evaluate how sorption to solid phases may affect sulfate and lithium mobility and therefore the time to reach the GWPS for these parameters.

Technical Memorandum - Monitored Natural Attenuation Field Investigation Status Update

GOLDER
MEMBER OF WSP

TECHNICAL MEMORANDUM

DATE December 15, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company (IPGC)

CC Brian Hennings - Ramboll

FROM Pat Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

MONITORED NATURAL ATTENUATION FIELD INVESTIGATION STATUS UPDATE, PRIMARY ASH POND (CCR UNIT 501) NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

The following Technical Memorandum summarizes the results received to date from the Monitored Natural Attenuation (MNA) Field Investigation completed by Golder Associates USA Inc. (Golder) for the Primary Ash Pond (PAP, CCR Unit 501) located at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. Data collected as a part of this investigation will be an integral part of the MNA Feasibility Demonstration for the PAP and will be used for IPGC's Illinois Part 845 Coal Combustion Residual (CCR) compliance program. A Site plan showing the PAP, existing Part 845 monitoring wells, and the MNA boring locations is provided in **Figure 1**.

This memorandum only includes laboratory analytical data that has been received to date. Golder will update this memorandum when the remaining data has been received and reviewed.

2.0 PROJECT SCOPE OF WORK

As part of the MNA Feasibility Demonstration, and ongoing discussions with IPGC, Golder completed the following activities as part of this Field Investigation:

- Screened for potential underground utilities in the vicinity of the proposed borings prior to completing any drilling or ground disturbance activities.
- Advanced a total of seven (7) soil borings ranging in depth from 15 to 90 feet below ground surface (ft bgs).
- Collected ten (10) soil samples from seven (7) soil borings for laboratory analysis.
- Collected groundwater samples from five (5) existing monitoring wells for laboratory analysis.

3.0 FIELD INVESTIGAITON

3.1 Private Utility Locate

Prior to conducting any work onsite, Golder reviewed Site plans/drawings provided by IPGC and/or Site representatives and met with Site representatives to assist in identifying underground utility locations in the vicinity

Golder Associates Inc.
13515 Barrett Parkway Drive, Suite 260, Ballwin, Missouri, USA 63021 T: +1 314 984-8800 F: +1 314 984-8770

Golder and the G logo are trademarks of Golder Associates Corporation

of the proposed borings. Golder also sub-contracted with GPRS to provide ground penetrating radar (GPR) and electromagnetic (EM) tracing services to screen the proposed boring locations in the field. All boring locations were cleared by GPRS personnel before drilling commenced.

3.2 Drilling and Aquifer Solids Sampling

Drilling was completed by Cascade Environmental Drilling (Cascade) using a roto-sonic drill rig under direct supervision of a Golder Geologist from August 17 – 21, 2021. Continuous soil core samples were obtained at each borehole location and were logged in the field by Golder personnel. Soils were classified according to the Unified Soil Classification System (USCS) and in accordance with the standard Golder Soil Logging Technical Procedure.

During the field investigation, seven (7) soil borings were advanced at the locations shown on **Figure 1**. Soil boring logs are provided in **Attachment A**. The following units were encountered during the field investigation (unit names are consistent with the Groundwater Monitoring Plan (Ramboll, 2021) in the Newton Part 845 Operating Permit):

- Shallow Saturated Zone – This zone is made up of the Upper Drift and the Upper Confining Units. The Upper Drift consists of low permeability silts and clays of the Peoria Silt and Sangamon Soil and the Hagarstown Member (Potential Migration Pathway) which consists of discontinuous sandier deposits. Below the Upper Drift is the Upper Confining unit, which consists of low permeability clay and silt of the Vandalia Till. The contact between the Upper Confining Unit and the underlying Uppermost aquifer ranges from approximately 467 feet above mean sea level (FT MSL) to 483 FT MSL in the borings completed for this investigation. Samples from the shallow saturated zone are shown in **Table 1**.
- Uppermost Aquifer – This zone consists of the Mulberry Grove Formation and is generally made up of fine to coarse, poorly to well graded sands, with occasional clayey sand layers and gravels. The formation is present between approximately 449 and 483 FT MSL. Samples collected from the uppermost aquifer are shown in **Table 1**.
- Lower Confining Unit – This unit consists of the Smithboro Till and is generally made up of compact glacial till consisting of low permeability silty clays and clayey silts with trace sand and gravel. The Till was present directly below the Uppermost Aquifer and the contact between these two units ranges from approximately 449 FT MSL to 474 FT MSL. Drilling was terminated in the Lower Confining Unit in most boreholes, therefore, evaluation of the full thickness of the unit was not completed as a part of this investigation. There were no samples collected from the lower confining unit.

Methane was encountered in soil boring SB-02, on August 18, 2021, while retrieving the soil from 60 to 80 feet below ground surface (FT BGS) within the bottom of the Shallow Saturated Zone and the top of the Uppermost Aquifer unit. Drilling was stopped until methane levels dropped below safe working levels and continued on August 19, 2021. Methane was only detected in this borehole during this investigation.

Ten (10) soil samples were collected for laboratory analysis from the soil borings (see **Figure 1** for sample location). Details regarding collected samples are included in **Table 1**.

Table 1: Laboratory Soil Sample Locations and Intervals Used for Laboratory Analysis

Borehole ID	Sample ID	Sample Depth (FT BGS)	Soil Type / Geologic Unit Sampled
N-SB-02	N-SB-02 (12.5 – 20.0)	12.5 - 20.0	Clayey Silt / Shallow Saturated Zone
	N-SB-02 (65.0 – 71.5)	65.0 – 71.5	Well Graded Sand /Uppermost Aquifer
N-SB-04	N-SB-04 (12.0 – 18.0)	12.0 – 18.0	Sandy Silty Clay / Shallow Saturated Zone
	N-SB-04 (38.8 – 45.4)	38.8 – 45.4	Clayey Sand / Uppermost Aquifer
N-SB-05	N-SB-05 (18.0 – 20.0)	18.0 – 20.0	Poorly Graded Sand / Shallow Saturated Zone
	N-SB-05 (60.0 – 67.1)	60.0 – 67.1	Poorly Graded Sand / Uppermost Aquifer
N-SB-14	N-SB-14 (44.2 – 52.0)	44.2 – 52.0	Sandy Clay / Uppermost Aquifer
N-SB-18	N-SB-18 (77.5 – 80.0)	77.5 – 80.0	Well Graded Sand / Uppermost Aquifer
N-SB-XPW01	N-SB-XPW01 (10.0 – 12.7)	10.0 – 12.7	CCR
N-SB-XPW04	N-SB-XPW04 (10.0 – 15.0)	10.0 – 15.0	CCR

Notes

1) FT BGS – Feet Below Ground Surface.

3.2.1 Soil Laboratory Analysis

Soil samples collected during the field investigation were placed in clean containers and properly labeled with sample location, depth, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to the following laboratories for analysis:

- Eurofins TestAmerica for 7-Step Sequential Extraction; and
- SiREM for the Batch Testing, Total Metals, Reitveld X-Ray Diffraction (XRD), leachability, Cation Exchange Capacity (CEC), and Total Organic Carbon (TOC) analyses.

The following laboratory analyses were conducted for each soil sample:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld XRD Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

Currently, only the results from Test America have been received, and are included in **Attachment B**. A separate Technical Memorandum will be provided when results from SiREM are completed.

3.2.2 Borehole Survey

On September 1, 2021, IngenAE completed a survey of the boring locations including the longitude/latitude of and elevation of each borehole location. Survey information is included in the boring logs in **Appendix A**.

3.3 Groundwater Sampling

Groundwater sampling was completed by Golder personnel on August 31, 2021. Five (5) existing monitoring wells were sampled, provided in **Figure 1**. Groundwater sample locations and adjacent borehole sample intervals for the MNA evaluation are included in **Table 2**.

Table 2: Groundwater Sample Locations

Well ID	Adjacent Borehole Sample
APW-02	N-SB-02 (12.5 – 20.0)
APW-04	N-SB-04 (12.0 – 18.0)
APW-05S (background)	N-SB-05 (18.0 – 20.0)
APW-05 (background)	N-SB-05 (60.0 – 67.1)
APW-14	N-SB-14 (44.2 – 52.0)

3.3.1 Groundwater Sample Laboratory Analysis

Groundwater samples collected during the field investigation were placed in clean containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to SiREM Laboratories to be included in batch testing analysis along with soil samples collected at adjacent boreholes. Results for the batch testing has not yet been completed and will be provided in a separate Technical Memorandum.

4.0 CLOSING

Golder appreciates the opportunity to serve as your consultant on this project. If you have any questions concerning this technical memorandum or need additional information, please contact the undersigned

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

APPENDIX B
Technical Memorandum – Surface Water Sampling

GOLDER
MEMBER OF WSP

TECHNICAL MEMORANDUM

DATE December 16, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company

FROM Patrick J. Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

SURFACE WATER SAMPLING SUMMARY, NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

Golder Associates USA Inc. (Golder) is pleased to submit this Technical Memorandum summarizing recent surface water sampling activities at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. During the field investigation, 28 samples were collected and sent for laboratory analysis from Newton Lake, which is adjacent to the Site, in the vicinity of the Primary Ash Pond (PAP, CCR Unit ID 501). A sample location map is provided in **Figure 1**.

2.0 PROJECT SCOPE OF WORK

The scope of work for this project consisted of the following:

- Preparation of a Site-specific Health, Safety, and Environment Plan (HASEP).
- Review of baseline data to determine sample locations and constituents for analysis.
- Collection of 28 surface water samples from Newton Lake.
- Preparation of a Technical Memorandum to summarize the sampling and the results.

3.0 FIELD INVESTIGATION

3.1 Health, Safety, and Environment Plan

This work was performed under a Site-Specific HASEP that was approved by IPGC. The HASEP was prepared in accordance with IPGC sub-contractor requirements and includes identification of occupation and health and safety hazards (risks) related to the field team, site conditions, specific risk controls, training requirements, personal protective equipment (PPE) requirements, and information on potential emergencies.

3.2 Surface Water Sampling Locations

Surface water sampling on Newton Lake was completed on October 4th and October 5th, 2021. To access the sample locations, Golder subcontracted with Environmental Restoration, LLC. (ER) to provide and operate an open boat with a low horsepower outboard motor. Twenty-eight (28) surface water samples were collected from Newton Lake at locations agreed upon prior to sampling between Golder and IPGC. Sample locations were

Golder Associates Inc.

Golder and the G logo are trademarks of Golder Associates Corporation

confirmed in the field using a Trimble Geo7X handheld GPS unit as displayed in **Figure 1**.

3.3 Surface Water Sample Collection and Results

At each sampling location, the field methods described in section 3.2.1.3 of the *Surface Water Sampling Work Plan – Newton Power Plan, Jasper County, Illinois* were completed as applicable. Field parameters including turbidity, pH, specific conductivity, dissolved oxygen, redox potential, and temperature were recorded prior to collecting each sample as shown on the field forms provided in **Appendix A**.

Surface water samples were placed in clean laboratory-supplied containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and the samples and COC were shipped to PDC Laboratories, LLC (PDC) for analysis. Sampling data validation was completed by Golder following receipt of the analytical data from PDC. A summary of the results is displayed in **Table 1** and the laboratory data packet from PDC as well as the data validation is provided in **Appendix B**.

No exceedances of the Site Groundwater Protection Standards (GWPS) used for Part 845 groundwater monitoring were noted based on our initial evaluation of the surface water sampling results. Further evaluation of the surface water data will be completed as part of the MNA evaluation for the site.

4.0 CLOSING

Golder appreciates the opportunity to continue to work on this project. Should you require any additional information about this technical memo, please feel free to contact the undersigned.

Sincerely,

Golder Associates Inc.

Jeffrey Ingram
Senior Project Geologist
JSI/PJB

Patrick J. Behling
Principal and Practice Leader

Notes:
1. Unit Abbreviations: °C - degrees celcius, µg/L - micrograms per liter, mg/L - milligrams per liter, SU - standard units, mV - millivolts, µS/cm - microsiemens per centimeter, NTU - nephelometric turbidity unit, pCi/L - picocuries per liter, FT BLE - feet below lake elevation.
2. ND - Non Detects. NDs reported as less than the Method Detection Limit (MDL) or adjusted Practical Quanitation Limit (PQL) basd on data validation.
3. Radium (226 + 228) is reported as the sum of the Radium 226 and the Radium 228 activity concentrations unless the sum of the Radium 226 and Radium 228 Minimum Detectable Concentrations (MDC) is higher in which case it is displayed as ND.
4. J - Flags are estimated values based on data validation.
5. Site Groundwater Protection Standards (GWPS) from Table 3-1, Background Groundwater Quality Standards from the Newton Groundwater Monitoring Plan.
6. For pH, the values represent the upper / lower limits. Values outside of these values represents a statistical exceedance.
7. No values are present above the Site GWPS, therefore, no highlighting is used in the table.

Notes:
1. Unit Abbreviations: °C - degrees celcius, µg/L - micrograms per liter, mg/L - milligrams per liter, SU - standard units, mV - millivolts, µS/cm - microsiemens per centimeter, NTU - nephelometric turbidity unit, pCi/L - picocuries per liter, FT BLE - feet below lake elevation.
2. ND - Non Detects. NDs reported as less than the Method Detection Limit (MDL) or adjusted Practical Quanitation Limit (PQL) basd on data validation.
3. Radium (226 + 228) is reported as the sum of the Radium 226 and the Radium 228 activity concentrations unless the sum of the Radium 226 and Radium 228 Minimum Detectable Concentrations (MDC) is higher in which case it is displayed as ND.
4. J - Flags are estimated values based on data validation.
5. Site Groundwater Protection Standards (GWPS) from Table 3-1, Background Groundwater Quality Standards from the Newton Groundwater Monitoring Plan.
6. For pH, the values represent the upper / lower limits. Values outside of these values represents a statistical exceedance.
7. No values are present above the Site GWPS, therefore, no highlighting is used in the table.

APPENDIX B

Laboratory Analytical Data

November 01, 2021

Jeffrey Ingram
Golder Associates, Inc
13515 Barrett Parkway Dr, Suite 260
Ballwin, MO 63021

RE: GOLDER VISTRA NEWTON

Dear Jeffrey Ingram:

Please find enclosed the **revised** analytical results for the **30** sample(s) the laboratory received on **10/5/21 4:30 pm** and logged in under work order **EJ00598**. All testing is performed according to our current TNI accreditations unless otherwise noted. This report cannot be reproduced, except in full, without the written permission of PDC Laboratories.

If you have any questions regarding your report, please contact your project manager. Quality and timely data is of the utmost importance to us.

PDC Laboratories. appreciates the opportunity to provide you with analytical expertise. We are always trying to improve our customer service and we welcome you to contact the Director of Client Services, Lisa Grant, with any feedback you have about your experience with our laboratory at 309-683-1764 or lgrant@pdclab.com.

Sincerely,

Gail J Schindler

Project Manager
(309) 692-9688 x1716
gschindler@pdclab.com

SAMPLE RECEIPT CHECK LIST

Items not applicable will be marked as in compliance

Work Order EJ00598

YES	Samples received within temperature compliance when applicable
YES	COC present upon sample receipt
YES	COC completed & legible
NO	Sampler name & signature present
YES	Unique sample IDs assigned
YES	Sample collection location recorded
YES	Date & time collected recorded on COC
YES	Relinquished by client signature on COC
YES	COC & labels match
YES	Sample labels are legible
YES	Appropriate bottle(s) received
YES	Sufficient sample volume received
YES	Sample containers received undamaged
NO	Zero headspace, <6 mm present in VOA vials
NO	Trip blank(s) received
YES	All non-field analyses received within holding times
YES	Short hold time analysis
YES	Current PDC COC submitted
NO	Case narrative provided

Certifications

CHI - McHenry, IL - 4314-A W. Crystal Lake Road, McHenry, IL 60050
TNI Accreditation for Drinking Water and Wastewater Fields of Testing through IL EPA Accreditation No. 100279
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory Registry No. 17556

PIA - Peoria, IL - 2231 W. Altorfer Drive, Peoria, IL 61615
TNI Accreditation for Drinking Water, Wastewater, Solid and Hazardous Material Fields of Testing through IL EPA Accreditation No. 100230
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory Registry No. 17553
Drinking Water Certifications/Accreditations: Iowa (240); Kansas (E-10338); Missouri (870)
Wastewater Certifications/Accreditations: Arkansas (88-0677); Iowa (240); Kansas (E-10338)
Solid and Hazardous Material Certifications/Accreditations: Arkansas (88-0677); Iowa (240); Kansas (E-10338)

SPMO - Springfield, MO - 1805 W Sunset Street, Springfield, MO 65807
USEPA DMR-QA Program

STL - Hazelwood, MO - 944 Anglum Rd, Hazelwood, MO 63042
TNI Accreditation for Wastewater, Solid and Hazardous Material Fields of Testing through KS KDHE Certification No. E-10389
TNI Accreditation for Wastewater, Solid and Hazardous Material Fields of Testing through IL EPA Accreditation No. - 200080
Illinois Department of Public Health Bacterial Analysis in Drinking Water Approved Laboratory, Registry No. 171050
Missouri Department of Natural Resources - Certificate of Approval for Microbiological Laboratory Service - No. 1050

Qualifiers

M	Analyte failed to meet the required acceptance criteria for duplicate analysis.
Q1	Matrix Spike failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q2	Matrix Spike Duplicate failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q3	Matrix Spike/Matrix Spike Duplicate both failed % recovery acceptance limits. The associated blank spike recovery was acceptable.
Q4	The matrix spike recovery result is unusable since the analyte concentration in the sample is greater than four times the spike level. The associated blank spike was acceptable.

Peoria, IL 61615

Entire Report Reviewed By:

Mark W. Beasley
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All radiochemical sample results for solids are reported on a dry weight basis with the exception of tritium, carbon-14 and radon, unless wet weight was requested by the client. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDA	Minimum Detectable Activity.
Rec.	Recovery.
RER	Replicate Error Ratio.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(T)	Tracer - A radioisotope of known concentration added to a solution of chemically equivalent radioisotopes at a known concentration to assist in monitoring the yield of the chemical separation.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C1	Tracer recovery limits have been exceeded; values are outside upper control limits.
J	The identification of the analyte is acceptable; the reported value is an estimate.
U	Below Detectable Limits: Indicates that the analyte was not detected.

DATA VALIDATION SUMMARY, VISTRA MNA – NEWTON, SURFACE WATER SAMPLING, DATA PACKAGE EJ00598, INORGANIC

The following is a summary of instances where quality control criteria in the functional guidelines were not met and data qualification was required:

- When a compound was detected in a blank (i.e. method, field), and the blank comparison criterion was not met, associated sample results were qualified as estimates (J) or non-detects (U).
- When duplicate criterion was not met, the associated sample result was qualified as an estimate (J for detects, UJ for non-detects).
- When matrix spike/matrix spike duplicate (MS/MSD) criterion was not met, the associated sample result was qualified as an estimate (J for detects, UJ for non-detects).
- When a compound was detected in a sample result between the MDL and the PQL the results were recorded at the detection value and qualified as estimates (J).

QA LEVEL II - INORGANIC DATA EVALUATION CHECKLIST

Company Name: Golder Associates, Inc
Project Manager: J. Ingram
Project Name: Vistra IL MNA - Newton
Project Number: 21454831
Reviewer: A. Muehlfarth
Validation Date: 11/19/2021

Laboratory: PDC and Pace Analytical National (Radium)
SDG #: EJ00598
Analytical Method (type and no.): Anions (EPA 300.0), Alkalinity (SM 2320B), TDS (SM 2540C), Sulfide (SM 4500 S2 F 2000*), Ferrous and Ferric Iron (SM 3500-Fe D MOD*),
Matrix: ☐ Air ☐ Soil/Sed. ■ Water ☐ Waste ☐ Dissolved and Total Metals (EPA 6020A/EPA 6010B*)
Sample Names N-D-2M, N-A-2D, N-A-2M, N-A-1, N-B-2D, N-B-2M, N-B-1, N-C-2D, N-C-2M, N-F-2M, N-F-1, N-UA-1D, N-UA-1M, N-E-2D, N-E-2M, N-E-1, N-D-1, N-D-2D, N-C-1, N-DUP-1, N-FB-1, N-I-2D, N-I-2M, N-I-1, N-UA-2D, N-UA-2M, N-G-2D, N-G-2M, N-G-1, N-F-2D

NOTE: Please provide calculation in Comment areas or on the back (if on the back please indicate in comment areas).

Field Information	YES	NO	NA	COMMENTS
a) Sampling dates noted?	x			10/4/2021 - 10/5/2021
b) Sampling team indicated?	x			EMS/JI/AMM
c) Sample location noted?	x			
d) Sample depth indicated (Soils)?			x	
e) Sample type indicated (grab/composite)?	x			Grab
f) Field QC noted?	x			See notes
g) Field parameters collected (note types)?	x			pH, Spec. Conductivity, turbidity, temperature, DO, ORP
h) Field Calibration within control limits?	x			
i) Notations of unacceptable field conditions/performances from field logs or field notes?		x		
j) Does the laboratory narrative indicate deficiencies?			x	

Note Deficiencies:

Chain-of-Custody (COC)	YES	NO	NA	COMMENTS
a) Was the COC properly completed?	x			
b) Was the COC signed by both field and laboratory personnel?	x			
c) Were samples received in good condition?	x			

General (reference QAPP or Method)	YES	NO	NA	COMMENTS
a) Were hold times met for sample pretreatment?	x			
b) Were hold times met for sample analysis?	x			
c) Were the correct preservatives used?	x			
d) Was the correct method used?	x			
e) Were appropriate reporting limits achieved?	x			
f) Were any sample dilutions noted?	x			See Notes
g) Were any matrix problems noted?	x			See Notes

QA LEVEL II - INORGANIC DATA EVALUATION CHECKLIST

Blanks	YES	NO	NA	COMMENTS
a) Were analytes detected in the method blank(s)?	x			See Notes
b) Were analytes detected in the field blank(s)?	x			See Notes
c) Were analytes detected in the equipment blank(s)?			x	
d) Were analytes detected in the trip blank(s)?			x	

Laboratory Control Sample (LCS)	YES	NO	NA	COMMENTS
a) Was a LCS analyzed once per SDG?	x			
b) Were the proper analytes included in the LCS?	x			
c) Was the LCS accuracy criteria met?	x			

Duplicates	YES	NO	NA	COMMENTS
a) Were field duplicates collected (note original and duplicate sample names)?	x			N-DUP-1 @ N-B-1
b) Were field dup. precision criteria met (note RPD)?		x		See Notes
c) Were lab duplicates analyzed (note original and duplicate samples)?	x			
d) Were lab dup. precision criteria met (note RPD)?		x		

Blind Standards	YES	NO	NA	COMMENTS
a) Was a blind standard used (indicate name, analytes included and concentrations)?			x	
b) Was the %D within control limits?			x	

Matrix Spike/Matrix Spike Duplicate (MS/MSD)	YES	NO	NA	COMMENTS
a) Was MS accuracy criteria met?		x		See Notes
Recovery could not be calculated since sample contained high concentration of analyte?			x	
b) Was MSD accuracy criteria met?		x		See Notes
Recovery could not be calculated since sample contained high concentration of analyte?			x	
c) Were MS/MSD precision criteria met?		x		See Notes

Comments/Notes:

Dilutions: Sulfate, Ferric Iron, Soluble Metals (excluding lithium), and Total Metals (excluding lithium) were analyzed at a dilution in multiple samples. No qualification was required.

Blanks:

B145055-BLK1: Alkalinity (2.50), associated with samples -01, -02, -05 through -09, -12 through -15, -17, -18, -20, 25, 27, and -30.

Sample results greater than 10x blank result, no qualification necessary.

B145143-BLK1: Alkalinity (2.50), associated with samples -03, -04, -10, -11, -16, -19, -22, -23, -24, -26, -29, -29.

Sample results greater than 10x blank result, no qualification necessary.

QA LEVEL IV - INORGANIC DATA EVALUATION CHECKLIST

Comments/Notes:

B145145-BLK1: Alkalinity (2.50), associated with samples -03, -04, -10, -11, -16, -19, -22, -23, -24, -26, -29, -29. Sample results greater than 10x blank result, no qualification necessary.

(MB) R3723020-1: Radium-228 (0.549 +/- 0.219). Associated with samples L1416552-20 through -30. Sample results <10x blank were qualified as an estimate (J).

FB:

N-FB-1 @ N-E-1: Dissolved Sodium (0.12). Associated result is >RL and 10x blank, no qualification necessary.

DUP:

N-DUP-1 @ N-B-1: DUP RPD exceeded limit (20%) for Total Iron (27.0%); Total Nitrate Nitrogen and Radium-228 detected in DUP and non-detect in sample.

The lab analyzed sample duplicates for Radium, TDS,

B144564-DUP2: RPD limit (5%) exceeded by TDS (27%). Associated with sample -20

B144565-DUP1: RPD limit (5%) exceeded by TDS (14%). Associated with sample -22

B144565-DUP2: RPD limit (5%) exceeded by TDS (7%). Associated with sample -23

B145055-DUP1: RPD limit (10%) exceeded by Alkalinity (15%). Associated with sample -01

MS/MSD:

B144698-MS1/B144698-MSD1: MS/MSD % recovery unusable since analyte concentration in sample is >4x spike for Chloride and Sulfate, associated with sample -29. Qualified as an estimate.

B144698-MS2/B144698-MSD2: MS/MSD % recovery unusable since analyte concentration in sample is >4x spike for Chloride and Sulfate, associated with sample -30. Qualified as an estimate.

B145177-MS1/B145177-MSD1: % recovery low and RPD exceeds limit for Ferrous Iron, associated with sample N-F-1. Qualified as an estimate.

QA LEVEL IV - INORGANIC DATA EVALUATION CHECKLIST

Data Qualification:

Sample Name	Constituent(s)	Result	Qualifier	Reason
N-B-1	Total Iron	210	J	DUP RPD exceeds limit
"	Total Nitrate Nitrogen	0.03	UJ	Detected in DUP, ND in sample
"	Radium-228	-0.0798 +/- 0.462	UJ	Detected in MB, result <10x blank; Detected in DUP, ND in sample
N-DUP-1	Total Iron	160	J	DUP RPD exceeds limit
"	Total Nitrate Nitrogen	0.04	J	Detected in DUP, ND in sample
"	Radium-228	1.49 +/- 0.509	J	"
N-DUP-1	TDS	170	J	Lab DUP RPD exceeds limit
N-I-2D	"	200	J	"
N-I-2M	"	170	J	"
N-D-2M	Alkalinity	75	J	"
N-G-1	Chloride	9.5	J	MS/MSD % recovery not calculated, result >4x spike
"	Sulfate	39	J	"
N-F-2D	Chloride	9.6	J	"
"	Sulfate	40	J	"
"	Radium-228	0.378 +/- 0.305	J	Detected in MB, result <10x blank
N-I-2D	"	0.582 +/- 0.345	J	"

XRF	X-ray fluorescence

1. EXECUTIVE SUMMARY

This report documents the geochemical conceptual site model GCSM describing the conditions of the groundwater in the vicinity of Newton Power Plant (NPP) Primary Ash Pond (PAP). A GCSM describes the geochemical processes that contribute to the mobilization, distribution, and attenuation of chemicals in the environment. This report describes the GCSM for parameters that have exceeded the GWPS in PAP groundwater and which will be addressed in the corrective action plan. The exceedances observed at the PAP were sulfate, total dissolved solids (TDS), and lithium.

Groundwater was monitored in two hydrostratigraphic units: the shallow upper drift/potential migration pathway (UD/PMP) and the deeper uppermost aquifer (UA). The uppermost aquifer is shallowest (*i.e.*, in closest proximity to the upper drift/primary migration pathway) on the east side of the PAP. Groundwater in the UD/PMP and eastern UA wells tend to be geochemically similar: groundwater from these locations tends to be more oxidizing, exhibit lower pH, and have a cation signature dominated by calcium and magnesium. Groundwater in the rest of the UA tends to be more reducing (exhibiting higher dissolved iron concentrations), have higher pH, and have a greater contribution of sodium and potassium to the cation signature. These results suggest some degree of hydraulic connection between the UD/PMP and UA east of the PAP.

Sulfate is the major contributor to TDS in the PAP groundwater. Therefore, processes that control sulfate concentrations also control TDS. Elevated sulfate concentrations were observed in shallow groundwater wells (screened in the upper drift/primary migration pathway) and uppermost aquifer wells located east of the PMP. Sulfate in CCR porewater and the UD/PMP groundwater is correlated with sodium, indicating that dissolution of sodium sulfate from the CCR material is the primary source of sulfate to the CCR porewater. Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. Potential sulfate attenuation mechanisms at the NPP PAP include sorption to solid-phase iron oxides. Based on results from laboratory batch testing, sulfate sorption may be more likely in the UA.

Lithium concentrations in groundwater are highest in UD/PMP and eastern UA groundwater. Although lithium was identified in solid samples located both upgradient and downgradient of the PAP, the similar distributions of lithium and sulfate suggest that CCR porewater is the primary source of lithium to the groundwater. The difference in groundwater lithium concentrations may be due to variability in porewater concentration or in attenuation to aquifer solids. Lithium in groundwater may be attenuated by sorption to exchangeable sites (readily reversible) or incorporation in clay mineral matrices (poorly reversible). According to results from laboratory batch testing, lithium may sorb to both UA/PMP and UA solids.

2. INTRODUCTION

This report documents the GCSM describing the conditions of the groundwater in the vicinity of NPP PAP. This GCSM serves as an attachment to thee NPP PAP Nature and Extent Report (NPP PAP N&E Report) and describes the chemical processes that contribute to the mobilization, distribution, and potential attenuation mechanisms of parameters that exceed the GWPS in PAP groundwater (*i.e.*, the nature of the exceedance parameters). Exceedances in PAP monitoring network wells were submitted to the Illinois Environmental Protection Agency (IEPA) in accordance with Illinois Administrative Code (I.A.C) Title 35 § 845 (35 I.A.C. § 845) for the second, third, and fourth quarters of 2023 (Ramboll, 2023, 2024a, b).The exceedances observed at the PAP were sulfate and total dissolved solids (TDS) at monitoring wells APW02, APW04, APW05S, and APW10 and lithium at monitoring well APW02. Wells APW02, APW04, and APW05 are screened in the upper drift/potential migration pathway (UD/PMP) and well APW10 is screened in the uppermost aquifer (UA).

2.1 Site Overview

A detailed overview of the site history, geology, and hydrogeology is presented in (NPP PAP N&E Report). Briefly, the NPP is located in Jasper County in the southeastern part of central Illinois, approximately seven miles southwest of the town of Newton. The PAP is located south of the NPP and surrounded by Newton Lake to the south, east, and west (**Figure 2-1**). Beyond the lake is agricultural land. The PAP is an unlined coal combustion residual (CCR) surface impoundment constructed in 1977 and used to manage CCR and non-CCR waste streams at the NPP. The PAP is known to contain bottom ash and fly ash derived from Illinois (pre-1997) and Powder River Basin (post-1997) coals.

There are six hydrostratigraphic units in the vicinity of the PAP: CCR, the UD/PMP, the upper confining unit, the UA, the lower confining unit, and the bedrock unit (from shallowest to deepest). The UD/PMP is composed of low permeability clays and silts of the Peoria Silt and Sangamon Soil with discontinuous sand and sandy clay lenses of the Hagarstown Member. The UA is a continuous zone of moderate permeability comprising poorly graded sand, silty sand, clayey sand, and gravel of the Mulberry Grove Formation. The UA is shallowest east of the PAP and deeper west of the PAP. Background and compliance monitoring well locations (per the Groundwater Monitoring Plan for the PAP; Ramboll, 2021) and the fourth quarter 2023 (Q4 2023) UA groundwater contours are shown on **Figure 2-1**. Groundwater flow in the UA is generally north to south beneath the center of the PAP (from APW05/APW06 toward APW09/APW15). Beneath the western portion of the PAP, flow is west to southwest converging towards a former surface drainage feature located west of the PAP and an area where the uppermost aquifer is lowest in elevation and has the highest hydraulic conductivity. Beneath the eastern portion of the PAP groundwater flows east to southeast (from APW05 toward APW11-APW14). The groundwater elevation within the PAP is greater than the groundwater elevation in the UD/PMP, indicating that there may be radial flow away from the unit within the UD/PMP.

2.2 Constituent Transport and Fate

Sulfate is the primary form of oxidized sulfur (S(VI)) in the environment and is a divalent oxyanion at pH values greater than 2 SU (Stumm and Morgan 1996). Sulfate in groundwater may sorb onto positively charged sites on solid metal oxide phases, most commonly iron and manganese oxides (Brown et al., 1999). The extent and strength of sulfate sorption to metal

oxide surfaces depends on pH, ionic strength, and oxide surface area available for sorption. Sulfate can also form insoluble complexes such as barite (BaSO4) (Nation Center for Biotechnology Information (NCBI), n.d.). Sulfate in groundwater may be reduced to elemental sulfur (S(0)) or sulfide (S(-II)) under sufficiently reducing conditions, a process governed by local microbial communities(Stumm and Morgan, 1996). Generally, reduced sulfur is less mobile in groundwater than sulfate. Reduced sulfur readily precipitates as metal sulfides and sorbs to solid phases (such as iron and manganese oxides; Stumm and Morgan, 1996).

TDS represents the mass of dissolved material in the water rather than a specific chemical constituent. Individual constituent contributions to TDS depend on both the concentration and molar mass of each contributor. Typically, major ions (*i.e.*, calcium, sodium, magnesium, potassium, chloride, sulfate, and carbonate species) represent the primary contributors to TDS. Therefore, source and sink terms that affect the primary contributors to TDS, such as sulfate, will ultimately have the greatest effect on TDS concentrations.

Lithium is a monovalent cation in the same periodic table group as sodium and potassium but has a smaller ionic radius. Lithium can sorb to exchangeable sites on metal oxides and clay minerals (Steinhoefel et al., 2021) but tends to be displaced by other cations during ion exchange. However, lithium sorbed to clays may be incorporated deeper into the mineral matrix for more permanent immobilization, a process which drives lithium fractionation in the environment (Li and Liu, 2020; Steinhoefel et al., 2021).

3. SOLIDS CHARACTERIZATION

3.1 Methods

Attachment 1 details CCR and aquifer solid boring locations and collection methodology. Both CCR and aquifer solid borings were located adjacent to monitoring wells at depth corresponding to screened intervals. **Table 3-1** summarizes boring identifiers and collection depths per **Attachment 1**; adjacent groundwater monitoring well names, used in this section to refer to the solid phase samples for easier comparison with groundwater results; and methods of analysis. Aquifer solids collected adjacent to APW05 represent upgradient (*i.e.*, background) conditions in the UA. The UD and PMP are discussed together because they are screened at similar depths and only one sample location represents the PMP (APW05S). The UD/PMP does not have background samples due to the hydraulic gradients between the pond and the UD/PMP.

Bulk solids characterization included cation exchange capacity (CEC), loss on ignition (LOI), X-ray fluorescence (XRF), and total metals. The CEC of a solid phase represents the negative surface charge, and therefore the potential to sorb cations such as lithium. Clays and organic matter in aquifer materials typically carry a negative surface charge and therefore tend to enhance cation exchange capacity. LOI represents the combustible portion of a solid material and is often an approximation of organic matter in a sample. Therefore, it may be inferred that organic matter (as quantified by LOI) is a major contributor to CEC if CEC and LOI are directly correlated in solid phase materials. XRF analysis is a test that measures the fluorescent x-rays emitted from a solid sample excited by a primary x-ray source to quantify the relative proportions of major elements in a sample. Results from XRF analysis are reported as oxides due to the borate fusion preparation method used.

Sequential extraction procedure (SEP) is an analytical method that uses progressively stronger reagents to dissolve solid phase fractions and measures the metal content associated with each fraction. The natures of the solid-phase fractions are functionally defined by the reagents used in each dissolution step and should therefore not be considered definitive characterizations.

Metals in aquifer solids samples were analyzed by SEP by Eurofins in 2021 and by SGS in 2023. The two labs used different methods for the SEP analysis: Eurofins used a seven-step procedure while SGS used a six-step procedure (**Attachment 2** and **Attachment 3** respectively for details). The extractions performed for the two test methods generally target a similar set of soil fractions, though variations in extraction conditions and reagents (**Table 3-2**) may lead to differences in absolute values. It is therefore helpful to define nomenclature to discuss results based on the target fractions. In the Eurofins 2021 seven-step procedure, step three ("Non-Crystalline Materials") represents, in part, non-crystalline iron and manganese oxides, while step four ("Metal Hydroxides") encompasses more crystalline iron and manganese oxides. In the SGS 2023 six-step procedure, the iron and manganese oxides (implicitly both non-crystalline and crystalline) are represented by a single "Fe and Mn Oxides" fraction (step four). In the following discussion, "metal oxides" is used to describe Eurofins steps three and four and SGS step four results across analyses. In the Eurofins 2021 seven-step procedure, the most recalcitrant (*i.e.,* resistant to mobilization) fractions are extracted separately as "Acid/Sulfides" (step six, extracted by aqua regia) and "Residual" (step seven, extracted by mixed acids including HF), whereas in the SGS 2023 six-step procedure the "Residual" (step six, extracted by mixed acids including HF) fraction will encompass all of the recalcitrant material. Therefore, "recalcitrant" is used to

describe Eurofins steps six and seven and SGS step six results across analyses. Differences in results between the two methods may also be due to sample heterogeneity as different depths may have been analyzed for the same location and hydrostratigraphic unit (summarized in **Table 3-1**). The percent contribution of each fraction was calculated by summing the results of fractions one through seven (excluding non-detect values) and dividing each detected result by that sum.

Mineralogy was determined using x-ray diffraction (XRD), TESCAN integrated mineral analysis (TIMA), and electron microprobe analysis (EMPA) with laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS). Identifying mineral phases aids in understanding attenuation mechanisms and aquifer capacity. XRD quantifies the relative proportion of crystalline mineral phases by comparing the x-ray diffraction patterns observed in a sample to those of known compounds in a reference database. TIMA identifies mineral phases using a combination of energy dispersive X-ray silicon drift detectors and backscattered electron and secondary electron detectors. EMPA analyzes the chemical composition of selected minerals (in this case, clays and micas). LA-ICP-MA is combined with EMPA to determine the lithium content of the clays and micas characterized by EMPA.

3.2 CCR

The SEP results for lithium, iron, and manganese in CCR materials are shown in **Figure 3-1** and tabulated in **Table 3-3**. Iron and manganese oxides and hydroxides tend to coat soil particles and carry a surface charge that vary based on pH. Iron and manganese oxides and hydroxides therefore represent possible sorption sites for many ions, including lithium and sulfate. There is considerable heterogeneity in lithium, iron, and manganese concentrations and dominant SEP fractions between the two sampling locations.

Results of XRD characterization of CCR solids are summarized in **Table 3-4** (lab report in **Attachment 4**). The material from XPW01 was primarily quartz with other major contributions from albite (a sodium-rich feldspar), microcline (a potassium-rich feldspar), and muscovite (a mica). In contrast, the material from XPW04 contained a lower proportion of quartz and had at least 8% contribution each from albite, calcite (calcium carbonate), diopside, perovskite, and gehlenite. Perovskite, gehlenite, and many of the trace (<5% abundance) minerals found in XPW04 (periclase, hematite, magnetite, mullite, and ganophyllite) were not detected in XPW01.

The SEP and XRD characterization of these two CCR samples suggest considerable variability in the chemical composition of the CCR stored in the PAP. Additionally, the differences in SEP fractions and minerals suggest differences in chemical mobility between the two samples. The ash composition and the local geochemical environment will control porewater composition within the unit.

3.3 Aquifer Solids

3.3.1 Bulk Characterization

Figure 3-2 shows the CEC and LOI results for solid samples from the aquifer solids. The UD and PMP samples typically had a higher CEC and lower LOI (suggesting lower organic content) relative to the UA samples. This suggests that the greater CEC of the UD and PMP samples is not related to greater organic matter content and may instead be due to clay mineral components.

3.3.2 Metals

Figure 3-3 shows the concentrations of iron, manganese, and lithium in each SEP fraction as well as the proportion each fraction represents out of the summed SEP results for samples analyzed in 2021 (**Figure 3-3a**) and 2023 (**Figure 3-3b**) (results tabulated in **Table 3-3**). Summed iron in the 2021 UD/PMP results was lowest in APW05S and highest in APW02. In 2023 analyses, summed SEP iron was lowest in APW05S and highest in APW04. APW05S may have the lowest concentrations of iron due to a smaller surface area of sandier PMP material. In both analyses, over 50% of the total iron was in the recalcitrant fractions followed by presence in the metal oxide fractions. The 2021 results indicate that in the UD/PMP, iron was not abundant in the non-crystalline material (<3% of iron). Summed SEP iron concentrations in the UA were similar to UD/PMP concentrations, and downgradient concentrations were not consistently different from the background location. Similar to in the UD/PMP, iron in UA samples in both the 2021 and 2023 analyses was most abundant in the recalcitrant fractions followed by the metal oxide fractions. Results from the 2021 samples indicate that iron in UA samples is present in more equal proportion between the non-crystalline material and metal hydroxide fractions in the UA relative to the UD/PMP. The exception to this is the sample from APW10, which has a distribution more similar to UD/PMP wells. Non-crystalline iron hydroxides tend to have a greater capacity to sorb ions compared to more crystalline phases (Trivedi & Axe, 2001). These results suggest that despite similar concentrations of iron in the combined non-crystalline material and metal hydroxide fractions in the UD/PMP and UA, solid-phase iron in many UA locations may have greater capacity for sorbing ions.

Summed SEP manganese concentrations in the UD/PMP were lowest in APW05S and highest in APW04 in both 2021 and 2023 results. Similar to iron, APW05S may have the lowest concentrations of manganese due to a smaller surface area of sandier PMP material. Summed SEP manganese concentrations at downgradient UA locations were not consistently different from the background location. The 2021 analysis of UD/PMP and UA samples shows manganese distributed throughout the carbonate, non-crystalline material, metal hydroxide, and recalcitrant fractions, whereas the 2023 analysis showed the majority of the manganese in the carbonate fraction in both UA and UD/PMP samples. The 2021 analysis shows that the proportion of manganese in the non-crystalline material in UA samples tended to be lower relative to the UD/PMP, potentially indicating greater manganese oxide crystallinity in the UA compared to the UD/PMP. These results indicate that manganese is predominantly in reactive, rather than recalcitrant, in UD/PMP and UA aquifer solids.

Summed SEP results for lithium are slightly higher in the UD/PMP relative to the UA in both 2021 and 2023 analyses. Summed SEP lithium concentrations at UA compliance locations were not consistently different from the background location. Results from 2021 SEP analysis indicate that lithium is predominantly in the recalcitrant fractions and organic fraction with a small proportion in the metal hydroxide fraction in both the UD/PMP and UA. Results from 2023 suggest that lithium is predominantly in the recalcitrant fractions with a some in the Fe Mn oxide fraction and even less in the organic, carbonate, and exchangeable fractions in both UD/PMP and UA samples. This discrepancy in organic phase results may be due to the difference in reagents used (see **Section 3.1**). The higher lithium concentrations in the UD/PMP relative to the UA are largely due to a higher concentration measured in the recalcitrant fractions.

In general, these results indicate that lithium is strongly associated with recalcitrant solid-phase fractions (rather than weakly bound in the water soluble or exchangeable fractions). The

presence of lithium in the recalcitrant fraction of the background location indicates some naturally occurring lithium within the aquifer. However, aqueous lithium in groundwater may contribute to the lithium found in the metal oxide fractions by co-precipitation or sorption and/or to the recalcitrant fractions by sorption to clays and incorporation into the clay matrix (Steinhoefel, et al., 2021).

Aquifer solid contents were also analyzed by X-ray fluorescence (XRF) (**Attachment 5**). XRF analyses determine the percent by weight of individual elements (reported as their oxides due to the analytical method) based on their electron properties. Unlike in XRD, the XRF results are not normalized to 100%, so some proportion of the mass remains uncharacterized. **Figure 3-4** shows XRF results for the 2023 solids samples (the 2021 samples were not analyzed by XRF; **Table 3-1**). The dominant element in the XRF analysis was silicon, a major component of quartz (omitted from **Figure 3-4** due to scale). The next most prevalent species was aluminum, the other major component of aluminosilicate minerals. Calcium and magnesium, the central species in many carbonate minerals, were also abundant in all samples with the exception of APW05S. Iron was also relatively abundant in the XRF analysis, consistent with SEP results.

3.3.3 Mineralogical Analysis

The mineralogical composition of UD/PMP and UA solid phase samples was characterized by XRD (**Attachment 4**) and TESCAN integrated mineral analysis (TIMA) (**Attachment 6**). **Figure 3-5** shows the XRD results for the 2021 and 2023 samples (tabulated with mineral formulas in **Table 3-4**). XRD results are normalized to 100% of the total weight, meaning that material not characterized by XRD is ignored in the percent calculation. The dominant crystalline mineral contributor to solids in the UD and UA is quartz, which is omitted from **Figure 3-5** due to scale. In most samples, the next most abundant mineral phases were the carbonate minerals dolomite ($CaMg(CO_3)_2$) and calcite ($CaCO_3$). This finding is consistent with the abundance of manganese associated with the carbonate fraction in the SEP analysis. The one notable exception to the general abundance of carbonate minerals is the 2023 sample of APW05S, which had minimal carbonate minerals detected in the 2023 sample. This is consistent with the low contributions of calcium and magnesium in the XRF results measured on a sample from the same depth range, 10 to 16.6 feet below ground surface (ft bgs). In contrast, the 2021 XRD analysis for APW05S (collected from 18-20 ft bgs; **Table 3-1**) showed more abundant carbonate minerals. This difference in results at APW-05S indicates variability in aquifer solid composition within the PMP at this location. Muscovite, a phyllosilicate clay mineral, is more prevalent in most UD/PMP samples relative to UA samples. Other mineral phases detected include tectosilicate minerals (albite, orthoclase, and microcline); other phyllosilicate minerals (biotite and chlorite); inosilicate minerals (diopside and actinolite); ankerite (a carbonate mineral with varying proportions of calcium, magnesium, iron, and manganese as cations); and fluorapatite (a phosphate mineral). These minerals do not show substantial variability between UD/PMP and UA samples. Montmorillonite was detected only in the 2023 APW05S sample. The UA compliance samples did now show consistent variability relative to the background sample results.

Three UD/PMP samples were analyzed by TIMA (**Figure 3-5**). These samples represented the same depth ranges as those analyzed by XRD in 2023 (**Table 3-1**). The dominant mineral phase in all samples was quartz (omitted from **Figure 3-5** due to scale). Mixed clays/micas represented the next most abundant phase at APW04 and APW05S and had notably lower contributions to APW02. Plagioclase minerals (the mineral family to which albite, which was identified in XRD analysis, belongs) were prevalent in all three samples. Calcite and dolomite were also prevalent

phases samples from APW02 and APW04 but not in APW05S, consistent with the 2023 XRD results for carbonate minerals.

Figure 3-6 shows the results of the EMPA and LA-ICP-MS analysis. Data for EMPA is reported as a mass percent for the simple oxide of each element (**Attachment 7**). For Figure 3-6, mass percent was converted to the moles of each element and the mole fraction was obtained by normalizing to total moles of all elements. Using mole fraction rather than mass percent allows for a direct comparison of the abundance of each element independent of their weight. EMPA analysis identified that the composition of mixed clays/micas is predominantly silicon and aluminum followed by either calcium (APW02) or iron (APW04 and APW05S) (**Figure 3-6**). Concentrations of lithium in mixed clays/micas were between 53.3 mg/kg and 93.3 mg/kg, which are higher than concentrations observed in the total soil analyzed by SEP. This suggests that lithium is at higher concentrations in mixed clays/micas than in other mineral phases.

4. AQUEOUS CHARACTERIZATION

The PAP porewater and groundwater data discussed in this section are summarized in **Table 4-1** and tabulated in full in **Attachment 8**. Over time, different parameters have been collected at different frequencies at various wells due to the regulatory history of the unit. Wells in this discussion are grouped by the hydrostratigraphic unit in which they are screened (CCR porewater, UA, or UD/PMP) and by their classification in the monitoring network (background [B] or compliance [C]). Background wells are only screened in the UA (APW05 and APW06); upgradient UD/PMP locations are not available due to the hydraulic gradients present around the unit (NPP PAP N&E Report). Porewater is evaluated as a mobile source endmember representing conditions within the unit since collection began in 2021 (**Table 4-1**).

4.1 Exceedance Parameters and CCR Tracers

Figure 4-1 shows boxplots of boron, sulfate, and lithium data collected since 2015 from porewater, background groundwater, and compliance groundwater. Boron and sulfate are commonly used CCR tracers, and sulfate and lithium are the exceedance parameters of interest at the PAP because TDS includes sulfate concentrations. Boron is higher in all CCR porewater wells relative to groundwater and is highest in XPW01. With the exception of UD well APW03, boron concentrations in compliance groundwater are within the range of background boron concentrations. Compliance wells with the highest sulfate concentrations are UD/PMP wells and UA wells located east of the PAP where the UA is closest to the ground surface (APW10, APW11, APW13, and APW14). These eastern UA wells represent the extent of elevated sulfate in the UA and are referred to as a group throughout this discussion. Sulfate concentrations at other UA wells were largely consistent with background. Lithium was highest in porewater location XPW01 and UD well APW02. Lithium concentrations were generally higher in the UD and in eastern UA wells compared to background and other UA compliance wells.

4.2 Redox/pH Summary

The reduction-oxidation (redox) potential and pH of water are major controls on the speciation of redox-active chemicals such as iron, manganese, and sulfate. The redox potential of a solution is often measured in the field as the oxidation-reduction potential (ORP). ORP measurements represent the average electrical potential of all chemical species an aqueous solution. Eh is the measure of redox potential based on the standard hydrogen electrode and is calculated by converting an ORP measurement using an equation appropriate to the type of electrode used in the ORP sensor (typically silver/silver chloride or calomel). All Eh values presented here were converted from ORP measurements based on the guidance[1] provided by the field meter manufacturer (Horiba).

Figure 4-2 summarizes all available[2] measurements of Eh and pH in boxplots. CCR porewater tends to have more reducing and more basic conditions relative to groundwater wells. Wells in the UD tend to have more oxidizing conditions relative to wells in the UA (including UA background) with the exception of APW10, which has the most oxidizing groundwater in the UA and is comparable to conditions in the UD/PMP. Other UA compliance wells have Eh potentials

[1] https://static.horiba.com/fileadmin/Horiba/Products/Process_and_Environmental/Water_Pollution/Instruction_Manuals/U-50/U-50_Manual.pdf
[2] Data from 2023 Q1 excluded due to a malfunctioning ORP meter.

consistent with background. Wells in the UD/PMP tend to have lower pH relative to UA wells, and UA compliance wells have pH values consistent with background locations.

4.2.1 Pourbaix Diagram

Pourbaix diagrams show the predicted speciation of a constituent across pH values and redox potentials at thermodynamic equilibrium. **Figure 4-3** shows the median of the three most recent groundwater samples (Q2, Q3, and Q4 of 2024) plotted on the Pourbaix diagrams for manganese and iron species. Iron and manganese oxides and hydroxides tend to coat soil particles and carry a surface charge that varies based on pH. Iron and manganese oxides and hydroxides therefore represent possible sorption sites for many ions, including lithium and sulfate. The median metal concentrations (below), groundwater temperature (17 degrees Celsius), and bicarbonate alkalinity concentration (504 mg/L) were used to generate the aqueous and mineral equilibrium phases present on the diagram. Using median results as inputs allows for an evaluation of the prevailing conditions in the groundwater; however, speciation predictions for individual sample points are approximate.

The median dissolved manganese concentration in groundwater (0.083 mg/L) was used in the manganese Pourbaix diagram (**Figure 4-3a**). Manganese oxides (represented by birnessite, a common manganese oxide in soils) are not expected to be stable at any of the Eh and pH values observed in the porewater and groundwater. At lower pH values, manganese is expected to exist as the reduced divalent cation (Mn^{++}). At higher pH values representative of background and UA groundwater conditions, samples plot closer to rhodochrosite ($MnCO_3$) stability. The pH at which rhodochrosite is expected to form depends on the alkalinity. In general, rhodochrosite is closer to saturation in UA samples relative to UD/PMP samples. Although rhodochrosite was not observed in the XRD or TIMA analysis, manganese was associated with the carbonate phase in the SEP analysis and reduced manganese may substitute as a cation in carbonate minerals.

The median dissolved iron concentration in groundwater (1.3 mg/L) was used in the iron Pourbaix diagram (**Figure 4-3b**). Crystalline iron oxide phases (hematite, magnetite, and goethite) are suppressed because these phases were not detected in XRD or TIMA samples. Amorphous solid-phase iron hydroxides ($Fe(OH)_3$(ppd)) are expected to be generally stable at UD/PMP locations and at UA well APW10. The pH and redox signatures of other UA groundwaters approaches the line of equilibrium between iron oxides, dissolved ferrous iron (Fe^{++}), and siderite. Although siderite was not observed in the XRD or TIMA analysis, ankerite with a composition of $CaFe(CO_3)_2$ was detected in XRD and a small amount of iron was associated with the carbonate phase in the SEP analysis. Therefore, a mixed cation carbonate phase may host iron. The position of the UA samples relatively close to the intersection of $Fe(OH)_3$(ppd), ferrous iron, and an iron carbonate suggest that equilibrium reactions between these phases may occur in the groundwater.

4.2.2 Manganese and Iron Concentrations

Figure 4-4 presents boxplots summarizing dissolved ferrous iron, dissolved iron, and dissolved manganese concentrations in groundwater and porewater. Aqueous manganese concentrations are lowest in the porewater, and the median concentration of manganese is higher in the UD/PMP than the UA. The highest UA manganese concentrations were in the eastern UA wells. Dissolved ferrous iron (measured on filtered samples in the field using a colorimetric kit with a range of 0 to 6 mg/L and photometer) and dissolved iron concentrations were highest in both background and downgradient UA samples. APW10 was a low outlier in dissolved iron concentrations in the UA,

which is consistent with the more oxidizing conditions at this well contributing to $Fe(OH)_3$ stability. The UD/PMP groundwater samples had the highest frequency of dissolved ferrous iron and dissolved total iron below the detection limits but had lower median and maximum concentration than in CCR porewater.

Median dissolved manganese and dissolved iron concentrations for each well are shown in **Figure 4-5** with respect to longitude (x axis) and depth below ground surface (y axis), with all wells projected onto the same plane. Dissolved manganese is higher in UD/PMP and shallow eastern UA wells, whereas dissolved iron concentrations are higher in UA wells (with the exception of APW10, which is a low outlier as discussed earlier) relative to UD/PMP wells. Dissolution of manganese-containing carbonate minerals due to lower pH may be the source of elevated manganese in UD/PMP and eastern UA wells. Based on the dissolved iron concentrations and the Pourbaix diagram (**Figure 4-3b**), conditions in the UD/PMP and APW10 groundwater are insufficiently reducing to cause substantial iron reduction, whereas the rest of the UA groundwater is more likely to be iron reducing.

4.3 Major Ion Distribution/Signature

The major ion signature of the porewater and groundwater can be visualized using a Piper diagram. A piper diagram of the three most recent sampling events for each sampling location is shown in **Figure 4-6**. Porewater is consistently characterized by a higher proportion (>65%) of monovalent cations (*i.e.*, Na^+ and K^+) relative to divalent cations (*i.e.*, Ca^{2+} and Mg^{2+}), with monovalent cation contributions at porewater locations XPW01 and XPW04 consistently greater than 95%. Porewater locations show considerable heterogeneity in anion composition by location. Porewater location XPW03 has a relatively even proportion of carbonate species (i.e., HCO_3^- and CO_3^{-2}) versus sulfate and chloride, while XPW04 has over 95% contribution from sulfate and chloride.

Background groundwater at the site has roughly equivalent proportions of monovalent and divalent cations and is dominated by carbonate species over sulfate and chloride. Groundwater in the UD/PMP has a predominantly divalent cation signature and a wide range of anion signatures (from 88% carbonate species at APW03 to 84% sulfate and chloride at APW02). Groundwater in the UA varies from a similar signature as background to having a more prevalent divalent cation signature similar to the UD/PMP, with APW10 representing this extreme in the UA wells.

4.4 Statistical Analyses Supporting Source/Sink Terms

4.4.1 Multivariate Analysis

Groundwater data is frequently defined by many chemical parameters and may therefore be described statistically as "multivariate". Principal components analysis (PCA) is a common multivariate statistical approach that simplifies multivariate data by combining those variables into a smaller number of new variables called principal components. This is possible because in multivariate data sets, there is often some correlation between variables. These correlations represent "redundant" information that may be mathematically removed by PCA. The principal components (PCs) represent linear combinations of the original data which maximize the variance between the samples, and which are uncorrelated with one another. The PCs explain some proportion of the variance in the data, with a robust PCA analysis usually explaining at least 50% of the variance in the first two PCs. PCA thereby allows patterns in the data to be more easily recognized and correlations between input variables to be assessed. The goal of this PCA was to

characterize chemical composition similarities and differences between porewater and groundwater.

The PCA analysis included samples collected since the beginning of 2021 through fourth quarter of 2023 to represent the most recent site conditions. Samples with a turbidity greater than 50 nephelometric turbidity units (NTU) were excluded from the analysis to mitigate the confounding influence of suspended solids. Geochemical parameters were excluded from PCA when greater than 50% of the measurements were either missing or below detectable limits. Individual samples were excluded for those samples missing greater than 50% of measured parameters. Any measurements that were below the reporting limit were assumed to be half the reporting limit. Results for pH were converted to milligrams per liter (mg/L) H^+ ion for consistency with other analytes. Any missing values were imputed (*i.e.,* interpolated based on the available data) using the nearest neighbor method. The final data set (**Attachment 9**) contained 2,352 parameter measurements (145 of which were imputed) from 147 individual groundwater samples at 22 wells in the vicinity of the PAP (four porewater wells, two background wells, and 16 compliance wells). All data were log transformed, scaled, and centered so that parameters with larger concentrations did not have disproportionate influence on the results.

The results of PCA can be understood by evaluating how parameters relate to one another and the relationships between individual samples and the PCs. A PCA biplot is used to show the relationship of parameters and individual samples with the first two PCs. In a PCA biplot, the axes represent the PCs, and arrows originating from the center represent the input parameters. The length of the arrows and alignment with the axes represent how strongly each input parameter contributes to the PCs, and the direction of the arrow along an axis represents the direction of the contribution (positive or negative). Each data point represents a sample plotted according to the PCs.

Figure 4-7 shows a biplot of the first two PCs with the percent of variance explained by each PC indicated in the axis label. Sulfate concentrations are shown in a log scale by point size. CCR porewater samples plot most negatively on PC 1 (the x axis) and mostly in the upper-left quadrant, indicating a correlation with boron and potassium. This is consistent with the elevated boron concentrations (**Figure 4-1**) and the dominance of monovalent cations shown by the Piper diagram (**Figure 4-6**). Groundwater tends to plot positively on PC1 and therefore tends to be more acidic and have higher contributions from divalent cations. UD and eastern UA groundwater tends to plot positively on PC2 (upper right quadrant), in the direction of higher sulfate concentrations. In contrast, background and other UA groundwater plot negatively on PC2 (lower right quadrant) in the direction of higher barium. The inverse relationship between sulfate and barium in the PCA are consistent with barite formation as a control on sulfate and barium concentrations. Manganese and calcium characterize the signature (*i.e.*, point in the direction) of UD groundwater, which is consistent with a mixed calcium manganese carbonate mineral contributing these elements to the groundwater.

The cyan outline (within upper right quadrant) is the 95% confidence ellipse (which encompasses the area where 95% of the sample points fall) for the UD/PMP locations with sulfate exceedances. The darker blue outline represents the 95% confidence ellipse for eastern UA groundwater samples. There is considerable overlap between 95% confidence ellipses for the UD/PMP locations with sulfate exceedances and the eastern UA samples, indicating that these groups of samples have similar chemical compositions. In contrast, background and other UA groundwater samples plot in a distinct group from the UD and eastern UA groundwater.

4.4.2 Correlation Analysis

Figure 4-9a shows a biplot of sodium and sulfate in porewater and UD/PMP groundwater (the hydrostratigraphic unit with the highest sulfate concentrations[3]) with the results of a least squares linear regression. Concentrations in this figure are presented in millimolar (mM) rather than in mg/L to understand potential reaction stoichiometry. The relationship between sulfate and sodium in porewater and UD/PMP samples is strong (coefficient of determination $R^2 = 0.77$) and statistically significant ($p < 0.001$). Sulfate in UD/PMP groundwater is correlated with sodium in a similar ratio as CCR porewater (**Figure 4-8a**). The consistent relationship between sodium and sulfate in the porewater and UD/PMP groundwater suggests a similar source of both elements. In the porewater wells XPW01 and XPW04, which have distinctly elevated sulfate and sodium concentrations, the R^2 is even stronger at 0.89 and the slope of this regression is 0.49 (**Figure 4-8b**). This slope indicating that each atom of sulfate is associated with approximately two atoms of sodium.

One potential attenuation sulfate attenuation mechanism in groundwater is precipitation as barite (**Section 2.2**). **Figure 4-9** show a biplot of barium and sulfate in PAP groundwater. Concentrations in this figure are presented in millimolar (mM) rather than in mg/L to understand potential reaction stoichiometry. Concentrations of lower sulfate correspond to higher barium concentrations in the most of UA wells, indicating that barite may affect concentrations of sulfate and barium in the deeper groundwater. However, the molar concentrations of barium are generally much lower than sulfate, indicating a limited capacity for barite formation to remove sulfate from groundwater.

[3] Sulfate and sodium concentrations in UA wells do not show sufficient variability to contribute to this analysis.

5. LABORATORY TEST RESULTS

In 2021, aquifer solids and groundwater samples were submitted by Golder WSP to SiREM laboratory to test sorption and desorption behavior of sulfate and lithium using batch testing. Batch test studies combine soil and groundwater collected from a site of interest to evaluate the sorption and desorption of chemical constituents (**Attachment 10**).

5.1 Adsorption Batch Tests

For the adsorption tests, soil from APW05 (60.0 to 67.1 ft bgs) was paired with groundwater from well APW-04, representing sorption to UA soils. Soil from APW04 (12 to 18 ft bgs) was paired with groundwater from APW-14, representing sorption to UD/PMP soils. Groundwater was spiked to known concentrations of lithium and sulfate before being combined with soil in soil:water ratios ranging from 2:1 to 1:20. Control samples using only groundwater were also prepared. Samples and controls were prepared under an anoxic atmosphere and incubated in the dark under anoxic conditions at room temperature for 7 days. At the end of the test, concentrations of lithium and sulfate in the water were analyzed. The total amount of lithium and sulfate in the water versus in the solids of each sample were plotted according to three sorption models: linear, Langmuir, and Freundlich (for additional details about these sorption models, see **Attachment 10**). The fit of each sorption model to the data was evaluated using the coefficient of determination (R^2).

The sulfate sorption data for the UD/PMP did not exhibit good fit for any sorption model (see **Attachment 10** for full results). The sulfate data for the UA showed a linear relationship and had a linear sorption coefficient (K_d) of 3.58 L/kg (**Figure 5-1**). These results suggest the potential for some sulfate sorption in the UA, but do not support sorption in the UD/PMP.

The lithium sorption data for both the UD/PMP and UA samples were strongly consistent with the Langmuir sorption model (**Figure 5-1**). The Langmuir sorption coefficients (K_L) were 1.2×10^9 L/kg for the UD/PMP solid sample and 4.2×10^8 L/kg for the UA solid sample. These results suggest the potential for lithium sorption in both the UD/PMP and UA, with somewhat greater sorption in the UA indicated by the higher K_L.

5.2 Desorption Batch Tests

For the desorption tests, APW-05 groundwater (representing UA background) was paired with soil from APW02 (N-SB-02 at 12.5 to 20 ft bgs; UD/PMP) and from APW07 (N-SB-07 at 65 to 71.5 ft bgs; UA) at a 1:10 soil:water ratio. Samples were prepared under an anoxic atmosphere. Three sets of samples were prepared in duplicate and incubated either under ambient conditions, with oxygen sparging (representing oxic groundwater conditions), or with hydrogen sparging (representing anoxic groundwater conditions). Samples were incubated at room temperature for 7 days. The ambient control pH and ORP values on day 7 were more similar to results from hydrogen sparged samples than oxygen sparged samples (**Figure 5-2**).

Desorption of sulfate and lithium from the UD/PMP sample was observed under all redox conditions (**Figure 5-3**). There were no substantial differences in desorption under different redox conditions, which may be due to the variability between duplicates. These results suggest that sulfate and lithium are sorbed to UD/PMP solids and that sorption is to some extent reversible under background groundwater conditions. No sulfate or lithium sorption was observed

from the UA sample under any redox condition (with the exception of lithium in one oxygen-sparged duplicate sample; **Figure 5-3**). This may indicate little sorption of sulfate and lithium to UA solids and/or that existing sorption is not reversible under background groundwater conditions.

6. GEOCHEMICAL CONCEPTUAL SITE MODEL

6.1 Source and Distribution of Sulfate and TDS

Following evaluation of the solids and aqueous geochemical data collected, the primary source of sulfate to the UD/PMP is the CCR porewater. No minerals were identified in aquifer material that would contribute sulfate to groundwater. Heterogeneity in UD/PMP sulfate concentrations may be due to differences in porewater contribution or differences in local porewater contributions.

Sulfates in CCR material are commonly created during desulfurization processes. Commonly, materials such as calcium oxide, calcium carbonates, or sodium carbonates are used. The process by which these materials remove sulfate from flue gas is the formation of solid phase sulfates (*e.g.*, $CaSO_4$ and Na_2SO_4). When sodium carbonates are used as the desulfurization material, other sodium salts (residual sodium chemicals) may also be present in the waste material as combustion by-products (Raclavska et al., 2010; Kalisz et al., 2023). The use of sodium bicarbonates and the presence of residual sodium chemicals in fly ash may drive a higher leaching potential of TDS, sulfates, and metals (Raclavska et al., 2010; Kalisz et al., 2023). The molar ratio between sulfate and sodium in high-sulfate porewater (*i.e.*, from XPW01 and XPW04) is consistent with sodium sulfate dissolution (**Figure 4-9b**), suggesting that the dissolution of sodium sulfates in CCR material within the PAP is the primary driver of high sulfate concentrations in the porewater. The heterogeneity of sodium and sulfate concentrations in the PAP porewater suggests sporadic placement within the PAP of CCR produced when sodium carbonate injection was used in desulfurization processes at the NPP from 1979 to 1996.

Sulfate exceedances in the UA, which occur exclusively on the east side of the PAP, are consistent with water migration from the UD/PMP. The UA is shallower on the eastern side of the PAP, putting the UD/PMP and UA in closer proximity (NPP PMP N&E Report, Figure 2-8). Water in the UD/PMP and eastern UA wells is similar in redox chemistry (**Section 4.2**) and geochemical signature (**Section 4.3** and **Section 4.4.1**), suggesting communication between the UD/PMP and UA in this area.

6.2 Source and Distribution of Lithium

Both naturally occurring soil and CCR porewater sources of lithium were identified (**Section 3.3** and **Section 4.1**). The bedrock underlying the site is shale (NPP PAP N&E Report). Lithium is naturally occurring in shale bedrock and overlying regolith and is released to groundwater during weathering processes (Steinhoefel et al., 2021). SEP analysis indicates lithium in recalcitrant aquifer solid fractions which is consistent with soil native lithium. However, lithium is higher in wells with elevated sulfate concentrations, suggesting a similar source as sulfate (**Figure 4-1**). Additionally, lithium concentrations are not elevated in background wells. It is therefore likely that the PAP is the source of most of the lithium contributing the GWPS exceedance.

6.3 Potential Attenuation Mechanisms

The primary mechanisms of sulfate in the environment are reduction to sulfide followed by mineral precipitation, sorption to positively charged sites on iron oxides, and precipitation as insoluble sulfate minerals (**Section 3.3**). Given the observed redox chemistry of the PAP groundwater, reduction of sulfate to sulfide is unlikely. Concentrations of barium in the groundwater are substantially lower than those of sulfate, suggesting limited capacity for barite precipitation to attenuate sulfate. The presence of iron oxides in the aquifer solids is indicated by

SEP results. Iron oxides may not have appeared in the XRD results due to poor crystallinity. Amorphous (*i.e.*, poorly crystalline) iron oxides tend to provide greater capacity for ion sorption (Trivedi and Axe, 2001). The surface charge on iron oxides is related to groundwater pH, with the surface carrying a more positive charge at more acidic pH values (Stumm and Morgan, 1996). The circumneutral to slightly acidic pH of the UD/PMP and the presence of iron oxides are therefore conducive to sulfate sorption and attenuation. However, the batch test results indicate that the capacity of UD/PMP solid phase materials to sorb sulfate may be saturated.

Lithium in groundwater may be attenuated by sorption to exchangeable sites or incorporation in clay mineral matrices. Lithium is readily displaced by exchangeable sites by other cations which are abundant in the PAP groundwater. However, some proportion of lithium may sorb to clay minerals, particularly aluminum hydroxides, and subsequently become incorporated into the mineral matrix with poor reaction reversibility (Pistiner and Henderson, 2003; Prodromou, 2016). TIMA results identified micas/clays as an abundant solid phase (>20%) at APW04 and APW05S, supported by the identification of clays in boring logs (NPP PAP N&E Report). The abundance of clays/micas was lower in APW02 (<10%) where aqueous lithium concentrations are highest. These results suggest that sequestration to clay minerals may provide a sink for lithium in the UD/PMP.

TECHNICAL MEMORANDUM

DATE December 15, 2021 **Project No.** 21454831

TO David Mitchell, Stu Cravens, Vic Modeer
Illinois Power Generating Company (IPGC)

CC Brian Hennings - Ramboll

FROM Pat Behling, Jeffrey Ingram - Golder **EMAIL Jingram@golder.com**

MONITORED NATURAL ATTENUATION FIELD INVESTIGATION STATUS UPDATE, PRIMARY ASH POND (CCR UNIT 501) NEWTON POWER PLANT, JASPER COUNTY, ILLINOIS

1.0 INTRODUCTION AND BACKGROUND

The following Technical Memorandum summarizes the results received to date from the Monitored Natural Attenuation (MNA) Field Investigation completed by Golder Associates USA Inc. (Golder) for the Primary Ash Pond (PAP, CCR Unit 501) located at the Newton Power Plant (NPP or Site) operated by Illinois Power Generating Company (IPGC) in Jasper County, Illinois. Data collected as a part of this investigation will be an integral part of the MNA Feasibility Demonstration for the PAP and will be used for IPGC's Illinois Part 845 Coal Combustion Residual (CCR) compliance program. A Site plan showing the PAP, existing Part 845 monitoring wells, and the MNA boring locations is provided in **Figure 1**.

This memorandum only includes laboratory analytical data that has been received to date. Golder will update this memorandum when the remaining data has been received and reviewed.

2.0 PROJECT SCOPE OF WORK

As part of the MNA Feasibility Demonstration, and ongoing discussions with IPGC, Golder completed the following activities as part of this Field Investigation:

- Screened for potential underground utilities in the vicinity of the proposed borings prior to completing any drilling or ground disturbance activities.
- Advanced a total of seven (7) soil borings ranging in depth from 15 to 90 feet below ground surface (ft bgs).
- Collected ten (10) soil samples from seven (7) soil borings for laboratory analysis.
- Collected groundwater samples from five (5) existing monitoring wells for laboratory analysis.

3.0 FIELD INVESTIGAITON

3.1 Private Utility Locate

Prior to conducting any work onsite, Golder reviewed Site plans/drawings provided by IPGC and/or Site representatives and met with Site representatives to assist in identifying underground utility locations in the vicinity

Golder Associates Inc.
13515 Barrett Parkway Drive, Suite 260, Ballwin, Missouri, USA 63021 T: +1 314 984-8800 F: +1 314 984-8770

Golder and the G logo are trademarks of Golder Associates Corporation

of the proposed borings. Golder also sub-contracted with GPRS to provide ground penetrating radar (GPR) and electromagnetic (EM) tracing services to screen the proposed boring locations in the field. All boring locations were cleared by GPRS personnel before drilling commenced.

3.2 Drilling and Aquifer Solids Sampling

Drilling was completed by Cascade Environmental Drilling (Cascade) using a roto-sonic drill rig under direct supervision of a Golder Geologist from August 17 – 21, 2021. Continuous soil core samples were obtained at each borehole location and were logged in the field by Golder personnel. Soils were classified according to the Unified Soil Classification System (USCS) and in accordance with the standard Golder Soil Logging Technical Procedure.

During the field investigation, seven (7) soil borings were advanced at the locations shown on **Figure 1**. Soil boring logs are provided in **Attachment A**. The following units were encountered during the field investigation (unit names are consistent with the Groundwater Monitoring Plan (Ramboll, 2021) in the Newton Part 845 Operating Permit):

- Shallow Saturated Zone – This zone is made up of the Upper Drift and the Upper Confining Units. The Upper Drift consists of low permeability silts and clays of the Peoria Silt and Sangamon Soil and the Hagarstown Member (Potential Migration Pathway) which consists of discontinuous sandier deposits. Below the Upper Drift is the Upper Confining unit, which consists of low permeability clay and silt of the Vandalia Till. The contact between the Upper Confining Unit and the underlying Uppermost aquifer ranges from approximately 467 feet above mean sea level (FT MSL) to 483 FT MSL in the borings completed for this investigation. Samples from the shallow saturated zone are shown in **Table 1**.
- Uppermost Aquifer – This zone consists of the Mulberry Grove Formation and is generally made up of fine to coarse, poorly to well graded sands, with occasional clayey sand layers and gravels. The formation is present between approximately 449 and 483 FT MSL. Samples collected from the uppermost aquifer are shown in **Table 1**.
- Lower Confining Unit – This unit consists of the Smithboro Till and is generally made up of compact glacial till consisting of low permeability silty clays and clayey silts with trace sand and gravel. The Till was present directly below the Uppermost Aquifer and the contact between these two units ranges from approximately 449 FT MSL to 474 FT MSL. Drilling was terminated in the Lower Confining Unit in most boreholes, therefore, evaluation of the full thickness of the unit was not completed as a part of this investigation. There were no samples collected from the lower confining unit.

Methane was encountered in soil boring SB-02, on August 18, 2021, while retrieving the soil from 60 to 80 feet below ground surface (FT BGS) within the bottom of the Shallow Saturated Zone and the top of the Uppermost Aquifer unit. Drilling was stopped until methane levels dropped below safe working levels and continued on August 19, 2021. Methane was only detected in this borehole during this investigation.

Ten (10) soil samples were collected for laboratory analysis from the soil borings (see **Figure 1** for sample location). Details regarding collected samples are included in **Table 1**.

Table 1: Laboratory Soil Sample Locations and Intervals Used for Laboratory Analysis

Borehole ID	Sample ID	Sample Depth (FT BGS)	Soil Type / Geologic Unit Sampled
N-SB-02	N-SB-02 (12.5 – 20.0)	12.5 - 20.0	Clayey Silt / Shallow Saturated Zone
	N-SB-02 (65.0 – 71.5)	65.0 – 71.5	Well Graded Sand /Uppermost Aquifer
N-SB-04	N-SB-04 (12.0 – 18.0)	12.0 – 18.0	Sandy Silty Clay / Shallow Saturated Zone
	N-SB-04 (38.8 – 45.4)	38.8 – 45.4	Clayey Sand / Uppermost Aquifer
N-SB-05	N-SB-05 (18.0 – 20.0)	18.0 – 20.0	Poorly Graded Sand / Shallow Saturated Zone
	N-SB-05 (60.0 – 67.1)	60.0 – 67.1	Poorly Graded Sand / Uppermost Aquifer
N-SB-14	N-SB-14 (44.2 – 52.0)	44.2 – 52.0	Sandy Clay / Uppermost Aquifer
N-SB-18	N-SB-18 (77.5 – 80.0)	77.5 – 80.0	Well Graded Sand / Uppermost Aquifer
N-SB-XPW01	N-SB-XPW01 (10.0 – 12.7)	10.0 – 12.7	CCR
N-SB-XPW04	N-SB-XPW04 (10.0 – 15.0)	10.0 – 15.0	CCR

Notes

1) FT BGS – Feet Below Ground Surface.

3.2.1 Soil Laboratory Analysis

Soil samples collected during the field investigation were placed in clean containers and properly labeled with sample location, depth, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to the following laboratories for analysis:

- Eurofins TestAmerica for 7-Step Sequential Extraction; and
- SiREM for the Batch Testing, Total Metals, Reitveld X-Ray Diffraction (XRD), leachability, Cation Exchange Capacity (CEC), and Total Organic Carbon (TOC) analyses.

The following laboratory analyses were conducted for each soil sample:

- 6010B for 7-step sequential extraction (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- EPA 6010B for Total Metals (Iron, Aluminum, Arsenic, Manganese, Lead, Lithium, Molybdenum, Cobalt, Calcium, Beryllium, Selenium, and Chromium);
- Bulk Mineralogy by Reitveld XRD Analysis;
- Cation Exchange Capacity (CEC) Analysis;
- Total Organic Carbon Analysis; and,
- SPLP Method 1312 Leachability Test (for CCR source samples only).

Currently, only the results from Test America have been received, and are included in **Attachment B**. A separate Technical Memorandum will be provided when results from SiREM are completed.

3.2.2 Borehole Survey

On September 1, 2021, IngenAE completed a survey of the boring locations including the longitude/latitude of and elevation of each borehole location. Survey information is included in the boring logs in **Appendix A**.

3.3 Groundwater Sampling

Groundwater sampling was completed by Golder personnel on August 31, 2021. Five (5) existing monitoring wells were sampled, provided in **Figure 1**. Groundwater sample locations and adjacent borehole sample intervals for the MNA evaluation are included in **Table 2**.

Table 2: Groundwater Sample Locations

Well ID	Adjacent Borehole Sample
APW-02	N-SB-02 (12.5 – 20.0)
APW-04	N-SB-04 (12.0 – 18.0)
APW-05S (background)	N-SB-05 (18.0 – 20.0)
APW-05 (background)	N-SB-05 (60.0 – 67.1)
APW-14	N-SB-14 (44.2 – 52.0)

3.3.1 Groundwater Sample Laboratory Analysis

Groundwater samples collected during the field investigation were placed in clean containers and properly labeled with well ID, project name, sampler initials, analyses to be performed, date, and time of collection. Sample information was logged on a chain of custody (COC) and shipped to SiREM Laboratories to be included in batch testing analysis along with soil samples collected at adjacent boreholes. Results for the batch testing has not yet been completed and will be provided in a separate Technical Memorandum.

4.0 CLOSING

Golder appreciates the opportunity to serve as your consultant on this project. If you have any questions concerning this technical memorandum or need additional information, please contact the undersigned

Project/Site: Newton Power Station - Illinois

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Qualifiers

Metals

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
B	Compound was found in the blank and sample.
F3	Duplicate RPD exceeds the control limit
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.
L	A negative instrument reading had an absolute value greater than the reporting limit

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Job ID: 140-24350-1

Laboratory: Eurofins TestAmerica, Knoxville

Narrative

Job Narrative
140-24350-1

Receipt
The samples were received on 8/24/2021 at 9:40am and arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.4º C.

Metals
7 Step Sequential Extraction Procedure

These soil samples were prepared and analyzed using Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0008, "7 Step Sequential Extraction Procedure". SW-846 Method 6010B as incorporated in Eurofins TestAmerica Knoxville standard operating procedure KNOX-MT-0007 was used to perform the final instrument analyses.

An aliquot of each sample was sequentially extracted using the steps listed below:

· Step 1 - Exchangeable Fraction: A 5 gram aliquot of sample was extracted with 25 mL of 1M magnesium sulfate (MgSO4), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 2 - Carbonate Fraction: The sample residue from step 1 was extracted with 25 mL of 1M sodium acetate/acetic acid (NaOAc/HOAc) at pH 5, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 3 - Non-crystalline Materials Fraction: The sample residue from step 2 was extracted with 25 mL of 0.2M ammonium oxalate (pH 3), centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 4 - Metal Hydroxide Fraction: The sample residue from step 3 was extracted with 25 mL of 1M hydroxylamine hydrochloride solution in 25% v/v acetic acid, centrifuged and filtered. 5 mL of the resulting leachate was digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 5 - Organic-bound Fraction: The sample residue from step 4 was extracted three times with 25 mL of 5% sodium hypochlorite (NaClO) at pH 9.5, centrifuged and filtered. The resulting leachates were combined and 5 mL were digested using method 3010A and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 6 - Acid/Sulfide Fraction: The sample residue from step 5 was extracted with 25 mL of a 3:1:2 v/v solution of HCl-HNO3-H2O, centrifuged and filtered. 5 mL of the resulting leachate was diluted to 50 mL with reagent water and analyzed by method 6010B. Results are reported in mg/kg on a dry weight basis.
· Step 7 - Residual Fraction: A 1.0 g aliquot of the sample residue from step 6 was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Results are reported in mg/kg on a dry weight basis.

In addition, a 1.0 g aliquot of the original sample was digested using HF, HNO3, HCl and H3BO3. The digestate was analyzed by ICP using method 6010B. Total metal results are reported in mg/kg on a dry weight basis.

Results were calculated using the following equation:

Result, µg/g or mg/Kg, dry weight = (C × V × V1 × D) / (W × S × V2)

Where:
C = Concentration from instrument readout, µg/mL
V = Final volume of digestate, mL
D = Instrument dilution factor
V1 = Total volume of leachate, mL
V2 = Volume of leachate digested, mL
W = Wet weight of sample, g
S = Percent solids/100

A method blank, laboratory control sample and laboratory control sample duplicate were prepared and analyzed with each SEP step in

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

order to provide information about both the presence of elements of interest in the extraction solutions, and the recovery of elements of interest from the extraction solutions. Results outside of laboratory QC limits do not reflect out of control performance, but rather the effect of the extraction solution upon the analyte.

A laboratory sample duplicate was prepared and analyzed with each batch of samples in order to provide information regarding the reproducibility of the procedure.

SEP Report Notes:

The final report lists the results for each step, the result for the total digestion of the sample, and a sum of the results of steps 1 through 7 by element.

Magnesium was not reported for step 1 because the extraction solution for this step (magnesium sulfate) contains high levels of magnesium. Sodium was not reported for steps 2 and 5 since the extraction solutions for these steps contain high levels of sodium. The sum of steps 1 through 7 is much higher than the total result for sodium and magnesium due to the magnesium and sodium introduced by the extraction solutions.

The digestates for steps 1, 2 and 5 were analyzed at a dilution due to instrument problems caused by the high solids content of the digestates. The reporting limits were adjusted accordingly.

Method 6010B: The sample duplicate (DUP) precision for preparation batch 140-54251 and analytical batch 140-55243 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B: The serial dilution performed for the following samples associated with batch 140-55243 was outside control limits: (140-24350-A-1-A SD ^5) and (140-24350-A-1-A SD ^50)

Method 6010B: The following samples were diluted due to the presence of titanium which interferes with Cobalt and Lead: N-SB-04 (12.0-18.0) (140-24350-7), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-02 (65.0-71.5) (140-24350-5). Elevated reporting limits (RLs) are provided.

Method 6010B: The following sample was diluted due to the presence of iron which interferes with Arsenic and Selenium: N-SB-02 (12.5-20.0) (140-24350-4). Elevated reporting limits (RLs) are provided.

Method 6010B: The following samples were diluted due to the nature of the sample matrix: N-SB-05 (18.0-20.0) (140-24350-1), N-SB-05 (60.0-67.1) (140-24350-2), N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (12.5-20.0) (140-24350-4), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-14 (44.2-52.0) (140-24350-6), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided for aluminum and calcium.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54371 and 140-54400 and analytical batch 140-55087 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The sample duplicate (DUP) precision for preparation batch 140-54401, 140-54485, 140-54486 and 140-54566 and analytical batch 140-55146 was outside control limits. Sample matrix interference and/or non-homogeneity are suspected because the associated laboratory control sample / laboratory control sample duplicate (LCS/LCSD) precision was within acceptance limits.

Method 6010B SEP: The laboratory control sample (LCS) and laboratory control sample duplicate (LCSD) for preparation batch 140-54486 and 140-54566 and analytical batch 140-55146 recovered outside control limits for the following analyte: Lithium. This analyte was biased high in the LCS/LCSD and was detected in the associated samples as an estimated value; therefore, the data have been

Job ID: 140-24350-1 (Continued)

Laboratory: Eurofins TestAmerica, Knoxville (Continued)

reported.

Method 6010B SEP: The following sample was diluted to bring the concentration of target analyte, calcium, within the calibration range: N-SB-05 (60.0-67.1) (140-24350-2). Elevated reporting limits (RLs) are provided.

Method 6010B SEP: The following samples were diluted due to the presence of silicon which interferes with Arsenic, Lead and Selenium: N-SB-18 (77.5-80.0) (140-24350-3), N-SB-02 (65.0-71.5) (140-24350-5), N-SB-04 (12.0-18.0) (140-24350-7), N-SB-04 (38.7-45.4) (140-24350-8), N-SB-XPW 04 (10.0-15.0) (140-24350-9) and N-SB-XPW 01 (10.0-12.7) (140-24350-10). Elevated reporting limits (RLs) are provided.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

General Chemistry
No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Review Items	Yes	No	NA	If No, what was the problem?
1. Are the shipping containers intact?	/			☐ Containers, Broken
2. Were ambient air containers received intact?			/	☐ Checked in lab
3. The coolers/containers custody seal if present, is it intact?	/			☐ Yes ☐ NA
4. Is the cooler temperature within limits? (> freezing temp. of water to 6 °C, VOST: 10°C) Thermometer ID : SC 71 Correction factor: +0.1	/			☐ Cooler Out of Temp, Client Contacted, Proceed/Cancel ☐ Cooler Out of Temp, Same Day Receipt
5. Were all of the sample containers received intact?	/			☐ Containers, Broken
6. Were samples received in appropriate containers?	/			☐ Containers, Improper; Client Contacted; Proceed/Cancel
7. Do sample container labels match COC? (IDs, Dates, Times)	/			☐ COC & Samples Do Not Match ☐ COC Incorrect/Incomplete ☐ COC Not Received
8. Were all of the samples listed on the COC received?	/			☐ Sample Received, Not on COC ☐ Sample on COC, Not Received
9. Is the date/time of sample collection noted?	/			☐ COC; No Date/Time; Client Contacted
10. Was the sampler identified on the COC?	/			☐ Sampler Not Listed on COC
11. Is the client and project name/# identified?	/			☐ COC Incorrect/Incomplete
12. Are tests/parameters listed for each sample?	/			☐ COC No tests on COC
13. Is the matrix of the samples noted?	/			☐ COC Incorrect/Incomplete
14. Was COC relinquished? (Signed/Dated/Timed)	/			☐ COC Incorrect/Incomplete
15. Were samples received within holding time?	/			☐ Holding Time - Receipt
16. Were samples received with correct chemical preservative (excluding Encore)?			/	☐ pH Adjusted, pH Included (See box 16A) ☐ Incorrect Preservative
17. Were VOA samples received without headspace?			/	☐ Headspace (VOA only)
18. Did you check for residual chlorine, if necessary? (e.g. 1613B, 1668) Chlorine test strip lot number:			/	☐ Residual Chlorine
19. For 1613B water samples is pH<9?			/	☐ If no, notify lab to adjust
20. For rad samples was sample activity info. Provided?			/	☐ Project missing info

Special notes:

Tessier sequential extraction

Mineralogy LIMS: MI7011-NOV22
Project: CA20I-00000-211-19465-03

3260 Production Way
Burnaby - British Columbia - V5A 4W4
Phone: 604-638-2349 FAX: 604-444-5486

ANALYSIS REPORT

Method Summaries *Test method information available upon request.*

S(T) and C(T): Total sulfur and total carbon by LECO, Method CSA06V
S(SO4): Sulfate by HCl digestion with ICP finish, Method CSA07V
S(S2-): Sulfide by calculation of S(T) - S(SO4)

TIC: Total inorganic carbon by coulometry, Method CSB02V
AP: Acid generating potential based on sulfide sulfur
NP: Modified neutralisation potential by excess acid addition and back titration to pH 8.3
Net NP: Net neutralisation potential = NP - AP
NPR: Neutralisation potential ratio = NP/AP

Metals by Aqua regia digest with ICP-OES/MS finish, Method ICP21B20/ICM21B20
Metals by multi-acid digest with ICP-OES/MS finish, Method ICP40Q12/IMS40Q12
Tessier Sequential Extraction - method available on request

This document is issued by the Company under its General Conditions of Service accessible at https://www.sgs.com/en/Terms-and-Conditions.aspx. Attention is drawn to the limitation of liability, indemnification and jurisdiction issues defined therein. Any holder of this document is advised that information contained hereon reflects the Company's findings at the time of its intervention only and within the limits of Client's instructions, if any. The Company's sole responsibility is to its Client and this document does not exonerate parties to a transaction from exercising all their rights and obligations under the transaction documents. Any unauthorized alteration, forgery or falsification of the content or appearance of this document is unlawful and offenders may be prosecuted to the fullest extent of the law. WARNING: The sample(s) to which the findings recorded herein (the "Findings") relate was(were) drawn and / or provided by the Client or by a third party acting at the Client's direction. The Findings constitute no warranty of the sample's representativeness of any goods and strictly relate to the sample(s). The Company accepts no liability with regard to the origin or source from which the sample(s) is/are said to be extracted. The findings report on the samples provided by the client and are not intended for commercial or contractual settlement purposes

Preliminary Data

SGS X-RAY DIFFRACTION LABORATORY REPORT

Quantitative X-Ray Diffraction by Rietveld Refinement

Report Prepared for:	*Environmental Services*
Project Number/ LIMS No.	*Custom XRD/MI4503-OCT21*
Sample Receipt:	*October 4, 2021*
Sample Analysis:	*October 8, 2021*
Reporting Date:	*November 2, 2021*

Instrument:	BRUKER AXS D8 Advance Diffractometer
Test Conditions:	Co radiation, 35 kV, 40 mA Regular Scanning: Step: 0.02°, Step time: 1s, 2θ range: 3-80°
Interpretations :	PDF2/PDF4 powder diffraction databases issued by the International Center for Diffraction Data (ICDD). DiffracPlus Eva and Topas software.
Detection Limit :	0.5-2%. Strongly dependent on crystallinity.

Contents:

1) Method Summary
2) Quantitative XRD Results
3) XRD Pattern(s)

Kim Gibbs, H.B.Sc., P.Geo.
Senior Mineralogist

Huyun Zhou, Ph.D., P.Geo.
Senior Mineralogist

ACCREDITATION: SGS Minerals Services Lakefield is accredited to the requirements of ISO/IEC 17025 for specific tests as listed on our scope of accreditation, including geochemical, mineralogical and trade mineral tests. To view a list of the accredited methods, please visit the following website and search SGS Canada - Minerals Services - Lakefield: http://palcan.scc.ca/SpecsSearch/GLSearchForm.do.

Method Summary

The Rietveld Method of Mineral Identification by XRD (ME-LR-MIN-MET-MN-D05) method used by SGS Minerals Services is accredited to the requirements of ISO/IEC 17025.

Mineral Identification and Interpretation:

Mineral identification and interpretation involves matching the diffraction pattern of an unknown material to patterns of single-phase reference materials. The reference patterns are compiled by the Joint Committee on Powder Diffraction Standards - International Center for Diffraction Data (JCPDS-ICDD) database and released on software as Powder Diffraction Files (PDF).

Interpretations do not reflect the presence of non-crystalline and/or amorphous compounds, except when internal standards have been added by request. Mineral proportions may be strongly influenced by crystallinity, crystal structure and preferred orientations. Mineral or compound identification and quantitative analysis results should be accompanied by supporting chemical assay data or other additional tests.

Quantitative Rietveld Analysis:
